HAM, in *Rural Economy*, formerly a name frequently applied provincially to a ſtinted common, or cow paiture.

HAM, in *Commerce*, &c. is uſed for a leg or thigh of pork, dried, ſeaſoned, and prepared to make it keep, and to give it a briſk agreeable flavour.

Weſtphalia hams, ſo much in vogue, are prepared by ſalting them with ſalt-petre, preſſing them in a preſs eight or ten days, then ſteeping them in juniper water, and drying them by the ſmoke of juniper-wood.

A ham may be ſalted in imitation of thoſe of Weſtphalia, by ſprinkling a ham of young pork with ſalt for one day, in order to fetch out the blood: then wiping it dry, and rubbing it with a mixture of a pound of brown ſugar, a quarter of a pound of ſalt-petre, half a pint of bay ſalt, and three pints of common ſalt, well ſtirred together in an iron pan over the fire till they are moderately hot: let it lie three weeks in this ſalting, and be frequently turned, and then dry it in a chimney.

There are different methods purſued in curing hams in different places, but the practice that is the moſt ready and certain, has not yet been ſhewn by any well-conducted ſet of experiments upon the ſubject. In thoſe diſtricts which are the moſt celebrated for the making of good hams, the buſineſs is performed by firſt rubbing them very hard with ſome bay or other ſalt, but moſt commonly the former; then letting them remain ſome time upon a ſtone-bench, in order that the brine may drain away and diſcharge itſelf. But on the contrary, in other caſes, they are covered up quite cloſe. After the lapſe of a few days, however, (whatever method has been at firſt followed,) they are again rubbed as hard as before, with the ſame kind of ſalt, in mixture with about half an ounce of ſaltpetre to each ham. They are then continued about a week longer on the bench, or in the ſalting tub

among the brine, when they are ſuppoſed ready to hang up to dry, which is often done on the ſides of large open chimneys, it being the practice with ſome to have them ſmoked by means of expoſure to the ſmoke of peat, coal, or ſome other ſort of fuel, while others cautiouſly avoid having them ſmoked at all.

Where they are not diſpoſed of before, they are uſually kept in theſe ſituations until the warm weather begins to ſet in, when they are packed up in caſks with ſtraw, or the ſeeds of oatmeal, and ſent to the market to be ſold.

The Survey of the County of Weſtmoreland ſtates the loſs in the weight of hams by drying to be ſo great as 20 per cent, but we can hardly ſuppoſe it to be quite ſo much, though it muſt evidently be very conſiderable, and ſhould not by any means be overlooked by the farmer or ſalter who cures any great number of pigs. The former ſhould indeed carefully weigh it before he enters upon the practice in any extenſive manner.

Ham, in *Scripture Biography*, the youngeſt ſon of Noah, who having indecently expoſed the nakedneſs of his father, was curſed by the patriarch in the line of Canaan and his poſterity. (See Canaan.) In conſequence of this irreverent act on the part of Ham, ſome have fancifully conjectured, that not only Ham and Canaan, but all their poſterity, became ſlaves, and the colour of their ſkin was ſuddenly rendered black; and accordingly they maintain, that all the blacks have deſcended from Ham and Canaan. Others have conſidered Ham as the introducer of wickedneſs after the flood, and they charge him with a variety of enormities and abominations. They ſuppoſe that he and his poſterity were principally concerned in the building of Babel, that they ſuggeſted the deſign, and formed the preſumptuous project. He is alſo repreſented as the firſt propagator of idolatry after the flood, and the inventor of magic and other ſimilar ſuperſtitions. Ham was the father of Cuſh, Mizraim, Phut, and Canaan: and it has been ſuppoſed that he peopled Africa, and that he dwelt in Egypt, the moſt fruitful part of this country. Africa is called the land of Ham in ſeveral paſſages of the Pſalms. Some have believed that Hammon, adored in Egypt and Lybia, was Ham, the ſon of Noah. But M. Baſnage is of opinion, that neither Ham nor Mizraim was ever in Egypt, but that their poſterity ſettled in this country, and called it by the name of their anceſtor. And as to Ham's being worſhipped as a god, and called Jupiter Ammon, he thinks that this is a miſtake occaſioned by ſimilitude of names, and that Jupiter Ammon was the ſun, to which divine honours have been paid at all times in Egypt.

Ham, in *Geography*, the name of two pariſhes of Eſſex, England, reſpectively called Eaſt and Weſt, from their relative ſituations to each other. Both are in the hundred of Becontree, and are ſeated in a flat marſhy tract of land, between the rivers Lee and Thames, to the S E. of London. Eaſtham contained, in the year 1801, 159 houſes and 1065 inhabitants. About one mile from the church is Green-ſtreet houſe, an ancient manſion, which progreſſively belonged to the Nevils, Holcrofts, Garrards, and Morleys. In the church is an old monument, with effigies of Edmund Neville, earl of Weſtmoreland, and his lady. The church contains ſome other monuments, and the ſouth wall of the chancel has ſome Saxon arches. This pariſh conſiſts of about 2000 acres of land; of which 900 are marſh, about 60 upland paſture, and the remainder arable; the greater part of the latter is uſually planted with potatoes, cabbages, and other vegetables. Weſt Ham pariſh contains 4500 acres of land, of which 1970 are arable, the remainder meadow and marſh. Here were formerly a weekly market and an annual fair, the charter for which was procured in 1253. In this pariſh was an abbey called Stratford Langthorne, founded in the year 1135, for monks of the Ciſtercian order. The abbey buildings were contiguous to the pariſh church, but nearly the whole have been deſtroyed and removed. The pariſh church, a large edifice, contains ſeveral monuments, ſome of which are fine and curious. In this pariſh are ſome water-works, which were eſtabliſhed in the year 1745, and are worked by a ſteam engine. Lyſons's Environs of London, vol. iv. p. 245, &c.

Ham, a town of France, in the department of the Somme, and chief place of a canton, in the diſtrict of Peronne, ſituated on the Somme. The place contains 1544, and the canton 9382 inhabitants, on a territory of 132½ kiliometres, in 21 communes. N. lat. 50° 11′. E. long. 3 9′.

Ham *Bluff*, a cape at the W. extremity of the iſland of Santa Cruz, in the Weſt Indies. N. lat. 17 51′. W. long. 63 34′.

HAMADA, a town of Arabia, in the province of Yemen; 24 miles S.E. of Chamir.

HAMADAN. See Amadan.

HAMADRYADES, formed of ἁμα, *together*, and δρυας, *dryad*, of δρυς, *oak*, in *Antiquity*, certain fabulous deities revered among the ancient heathens, and believed to preſide over woods and foreſts, and to be encloſed under the bark of oaks.

The Hamadryades, ἁμαδρυαδες, were ſuppoſed to live, and die with the trees to which they were attached; as is obſerved by Servius on Virgil, Eclog. x. ver. 62, after Mneſimachus, the ſcholiaſt of Apollonius, &c. who mentions other traditions relating to this ſubject.

The poets, however, frequently confound the Hamadryades with the Naiads, Napææ, and rural nymphs in general: witneſs Catullus, Carm. lxviii. ver. 23. Ovid. Faſt. iv. 229. Met. i. ver. 695. xiv. ver. 628. Propertius, Eleg. xx. 32. Virg. Ecl. x. ver. 64. Georg. iv. ver. 382, 383.

Feſtus calls them *Querquetulanæ*, as being iſſued or ſprung from oaks.

An ancient poet, Pherenicus, in Athenæus, lib. iii. calls the vine, fig-tree, and other fruit trees, hamadryades, from the name of their mother the oak.

This common idea among the ancients, of nymphs or intellectual beings annexed to trees, will account for their worſhipping of trees; as we find they did, not only from their poets but their hiſtorians. Livy ſpeaks of an ambaſſador's addreſſing himſelf to an old oak, as to an intelligent perſon and a divinity. Lib. iii. § 25.

HAMADRYAS, in *Botany*, ſo named by Commerſon, from ἁμα, *accompanying*, and δρυς, *a grove*; becauſe it inhabits woods or ſhady places. The word, though at firſt ſight appearing to be compounded of another generic name, (ſee Dryas,) is not really ſo, and therefore not exceptionable. Juſſ. 232. Lamarck. Dict. v. 3. 67.—Claſs and order, *Dioecia Polyandria*. Nat. Ord. *Multiſiliquæ*, Linn. *Ranunculaceæ*, Juſſ.

Gen. Ch. Male. *Cal.* Perianth of five or ſix ovate, pointed, concave, deciduous leaves. *Cor.* Petals ten or twelve, linear, acute, ſpreading, twice as long as the calyx, without any nectariferous pore at their baſe. *Stam.* Filaments numerous, ſhorter than the calyx, thread-ſhaped; anthers vertical, elliptical, obtuſe, thick-edged, of two marginal cells.

Female, *Cal.* and *Cor.* as in the male. *Piſt.* Germens ſuperior, numerous, collected into an ovate head; ſtyles none; ſtigmas ſimple, ſlightly reflexed. *Peric.* none. *Receptacle* roundiſh.

roundiſh. *Seeds* numerous, ovate, compreſſed, hooked at the point.

Eſſ. Ch. Male, Calyx of five or ſix leaves. Petals twice as many, linear, deſtitute of a nectary. Stamens about fifty.

Female, Cal. and Cor. as in the male. Germens collected into a head. Stigma ſimple. Seeds naked.

1. H. *magellanica*. Lamarck. Gathered by Commerſon in the ſtraits of Magellan. Mr. Menzies found the ſame in February, 1787, half way up the mountains at Staten land. The *root* is perennial, conſiſting of long ſtraight fibres, as in other plants of this natural family. *Stem* none. *Leaves* few, radical, erect, deeply divided into three parts, which are more or leſs lobed and cut; ſmooth above; downy or cottony beneath. *Footſtalks* three or four inches long, being twice or thrice the length of the leaf, ſtout, downy, dilated and ſheathing at their baſe. *Flower-ſtalk* ſolitary, rather taller than the leaves, naked, ſimple, very cottony in the upper part. *Flowers* few, denſely ſpiked, pale green or yellowiſh, about half an inch in diameter, the males feweſt, on a more ſlender ſtalk; females about four or five in the ſpike, from a different plant. We have not ſeen the ripe fruit, but there is every appearance of its being as above deſcribed.

The flowers, except their being dioecious, and the general habit, though herbaceous, of this plant, bear much reſemblance to the *Knowltonia* of Saliſbury and Sims, Curt. Mag. t. 775, which is *Anamenia* of Ventenat, Jard. de la Malm. t. 22, *Adonis capenſis*, *veſicatoria* and *ſilia* of Linnæus, but the fruit of the latter genus is a berry or drupa, and the ſtigmas are accompanied by ſtyles.—The *Hamadryas* either varies in the number of ſegments, and degree of downineſs, of its leaves, perhaps according to its degree of elevation above the ſea, or Mr. Menzies' is another ſpecies, its leaves being much leſs cut than in Commerſon's ſpecimens, and very woolly. We are, however, hence inclined to aſſent to Mr. Saliſbury's idea, that the above *Knowltoniæ* are rather varieties than ſpecies, for they all differ from each other much in the ſame manner.

Hamadryas, in *Zoology*, the name given by Linnæus to an animal of the baboon tribe. See Simia.

HAMAH, or Hama, in *Geography*, a town of Syria, ſituated in a narrow valley, on the banks of the Orontes, containing about 4000 inhabitants, and poſſeſſing ſome trade, from its ſituation on the road from Aleppo to Tripoli. This town is celebrated for its water-works; the wheels are the largeſt in that country, being 32 feet in diameter, and to the circumference are faſtened troughs, ſo diſpoſed as to fall in the river, and when they reach the vertex of the wheel, the water is diſcharged into a reſervoir, whence it is conveyed by conduits to the public and private baths. The gardens of Hamah are pleaſant and productive; and the ſoil in the adjacent country is well adapted to wheat and cotton; but agriculture, expoſed to the rapine of the Motſallam and the Arabs, is in a very languiſhing condition. The chiefs or ſcheiks of Hamah are very famous, as they are deſcended from Mahomet. Abulfeda, the great Arabian hiſtorian and geographer, was prince of Hamah about the year 1345, and he reigned three years, the ſovereign power being in his family. The Maronites built a chapel and a tomb in this place, whence ſoon aroſe a convent, very celebrated in that part of Syria; 62 miles S.S.W. of Aleppo. N. lat. 34 45'. E. long. 37° 10'.

HAMAM, a town of Africa, in the eaſtern province of Algiers, celebrated for its baths, anciently called "Aquæ Tibilitanæ;" 45 miles E. of Conſtantina.

HAMAMELIS, in *Botany*, ἁμαμηλὶς, an ancient Greek name from ἅμα, *accompanying*, and μηλέα, or μῆλις, an *apple-tree*, becauſe the plant which bore it bloſſomed at the ſame ſeaſon, and is ſuppoſed by modern botaniſts to have been the *Meſpilus Amelanchier*, or ſomething near it. Linnæus choſe this now unoccupied name for a new American ſhrub, which Mitchell had called *Trilopus*, in his letters. The reaſon of its application in the preſent inſtance ſeems to be, that as the fruit is a whole year in ripening, it accompanies the flowers in autumn, which are deſtined to produce the next year's fruit.—Linn. Gen. 66 Schreb. 90. Willd. Sp. Pl. v. 1. 701. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. ed. 2. v. 1. 275. Juſſ. 288. Lamarck. Illuſtr. t. 88.—Claſs and order, *Tetrandria Digynia*. Nat. Ord. *Amentaceæ*, Linn. *Berberides*, Juſſ.

Gen. Ch. *Cal.* Perianth double, permanent, inferior; the outer of two roundiſh ſmaller leaves; inner of four erect, ovate-oblong, obtuſe, equal leaves. *Cor.* Petals four, linear, equal, very long, obtuſe, reflexed. Nectary of four truncated ſcales, attached to the petals. *Stam.* Filaments four, linear, alternate with the petals, ſhorter than the calyx; anthers vertical, elliptical, of two cells, each opening by a valve. *Piſt.* Germen ſuperior, ovate, villous; ſtyles two, the length of the ſtamens; ſtigmas capitate. *Peric.* Capſule coriaceous, ſupported by the baſe of the calyx, ovate, two-horned, with two cells, and two valves. *Seeds* ſolitary, oblong, poliſhed.

Eſſ. Ch. Calyx double; the outer of two, inner of four leaves, inferior. Petals four, with a nectariferous ſcale to each. Anthers with two lateral valves. Capſule of two cells. Seeds ſolitary.

Obſ. The paradoxical remarks on this plant in *Linn. Mant.* 333, aroſe from the author having confounded with it the *Fothergilla*, ſee that article, which circumſtance the younger Linnæus overlooked when he deſcribed the latter in his *Supplementum*, or he doubtleſs would have explained the matter. What is in the *Mantiſſa* termed the Carolina monoecious kind, is *Fothergilla*, the likeneſs of whoſe leaves to *Hamamelis* cauſed the miſtake. Willdenow and Reichard copy theſe remarks, and Schreber copies the laſt-named writer, as if his obſervation had been original. Dr. Garden was well aware of the differences between theſe genera, and intended to have called the *Fothergilla* by a name alluding to the other, *Anamelis*.

The only ſpecies is,

1. H. *virginiana*. Linn. Sp. Pl. 180. Mill. Illuſtr. t. 10. (Hamamelis; Du Hamel. Arb. 287. t. 288. Gron. Virg. 22.)—Native of Virginia and Carolina, where it is called, according to Clayton, Witch-Hazel, a name corrupted from Wych-Hazel, and applied, we preſume, on account of ſome reſemblance to the Elm, ſo denominated in England. The *leaves* however, and aſpect of the plant, more reſemble the Hazle-nut, or ſtill more the Alder. The *flowers* are in little axillary bunches, with downy ſtalks, bracteas, and calyx, their petals long, whitiſh and conſpicuous. They come out late in autumn, or early in ſpring, before the leaves, and the *capſules*, which are ſhaped ſomewhat like a mitre, ſcarcely half an inch long, are not perfected till the following ſummer. Linnæus's remark, that the flowers are polygamous, ſeems correct, and probably that circumſtance is owing to the caſual imperfection of one or other of their organs, from the precarious ſeaſon of their coming forth; yet hence Walter has made three different ſpecies in his *Flora Caroliniana*, 255, but Willdenow judiciouſly declined adopting theſe.

HAMAM-ET, in *Geography*, a ſea-port town of Africa,

in the kingdom of Tunis, on the E. coaſt, in a bay or gulf of the Mediterranean, to which it gives name. The pillars, the blocks of marble, and other tokens of antiquity which are found in this place, were brought from the neighbouring ruins of Caſſir Aſcite, the "Civitas Siagitana" of the ancients. The name is derived from the Hamam, or wild pigeons, that copiouſly breed in the adjacent cliffs; 30 miles S. of Tunis. N. lat. 36° 13'. E. long. 10° 38'.

HAMAPATLI, a town of Hindooſtan, in the province of Madura; 17 miles W. of Madura.

HAMAPEL, a town of Hindooſtan, in the Carnatic; 14 miles E. of Tanjore.

HAMARA, a town of Greater Bucharia; 30 miles E. of Saganien.

HAMATH, in *Ancient Geography*, a celebrated city of Syria, ſuppoſed to be *Emeſa*, on the Orontes, and now called *Homs*. See EMESA.

HAMAXOBII, HAMAXOBIANS, in *Ancient Geography*, a people who had no houſes, but lived in carriages.

The word is formed from ἁμαξα, a *carriage* or *chariot*, and βιος, life.

The Hamaxobii, called alſo *Hamavobitæ*, were an ancient people of Sarmatia Europæa, inhabiting the ſouthern part of Muſcovy, who, inſtead of houſes, had a ſort of tents made of leather, and fixed on carriages, to be ready for ſhifting and travel.

HAMAZAN, in *Geography*, a town of Abyſſinia; 40 miles W. of Arkeeko.

HAMBATO, an affiento, or department, in the juriſdiction of Riobamba, in the province of Quito, ſituated in S. lat. 1° 41' 40", and 22' W. of the city of Quito. In 1523 it was an Indian town, and in the following year marſhal Diego de Almagro laid the foundation of the preſent town. It ſtands on a very large plain, ſurrounded by mountains, particularly on the N. ſide, which is bounded by Chimborazo, from the foot of which it is at no great diſtance. On the S. ſide is a lake, called "Colta," about a league in length and three quarters of a league in breadth, where are a great number of wild geeſe and gallaretas; and its banks are covered with plantations. The principal ſquare and ſtreets are regular, ſtraight, and airy; the houſes, built of a light ſtone, are low, on account of the earthquakes. The Indians, who inhabited this place, were, before their converſion to Chriſtianity, known by the name of Puruayes, and are to this day diſtinguiſhed from all the other Indians in the whole province. It has two churches, ſeveral convents, a nunnery, and a hoſpital, in a ruined ſtate. On the W. ſide of the affiento is a river, cut into ſmall trenches, for watering the adjoining fields, which are thus rendered ſo fertile, that they produce corn through the whole year. The inhabitants amount to between 10 and 20 thouſand. The magiſtrates are regidores, who are always perſons of the firſt diſtinction. The air is colder here than at Quito, on account of its vicinity to the mountain of Chimborazo; the uncomfortable ſeaſon laſts from December to June, the N. and N.W. winds then principally prevailing; but it is free from the violent tempeſts that are common at Quito. Here are many conſiderable plantations and farms; and in the number and ſize of its manufactories, it ſurpaſſes every other part of this province. The Indians are much employed in weaving, particularly thoſe of the village of Guano, who are famous for their manufacture of worſted ſtockings, being amply ſupplied with wool, from the ſheep which abound in this juriſdiction. The ſoil is very fertile, producing plenty of grain and pulſe. The inhabitants, in their manners and cuſtoms, reſemble thoſe of Quito. This department includes ſix villages.

HAMBERGER, GEORGE EDWARD, in *Biography*, profeſſor of chemiſtry and of the practice of medicine in the univerſity of Jena, was born in that city on the 21ſt of December 1697, his father being profeſſor of mathematics in the ſame univerſity. From his earlieſt years he had evinced a diſpoſition to the ſtudy of anatomy, and was accuſtomed to ſteal from his parents, who deſtined him for the church, to attend the lectures of Slevoigt on that ſubject. After the death of his father, he relinquiſhed even the ſtudy of the mathematics, to which he had applied himſelf during ſeveral years, and gave up his attention excluſively to medical purſuits. In 1721 he took the degree of M.D., and in 1726 was appointed profeſſor; and he held the chair of the practice of medicine at the time of his death, which occurred on the 22d of June 1755.

Hamberger is entitled to the merit of having illuſtrated phyſiology by the doctrines of philoſophy, and of having rendered both more popular than they had ever before been in Germany; but in the diſpute with the celebrated Haller, in which the publication of his hypotheſis concerning reſpiration involved him, and which was carried on with conſiderable aſperity, he was altogether in error; he lived long enough, indeed, to be convinced of the weakneſs of his hypotheſis, which he avowed to his friends. It was contained in a diſſertation, "De Reſpirationis mechaniſmo et uſu genuino," publiſhed in 1727, and conſiſted of a ſuppoſition, that there was a quantity of air within the cavity of the pleura, as a counterbalance to the air taken in by reſpiration. He alſo aſſerted that the internal intercoſtal muſcles were employed to depreſs the ribs, and the external to elevate them. His other works are, "Elementa Phyſices, Methodo Mathematica in uſum Auditorum conſcripta," Jenæ 1727, 8vo. cum fig.—"Diſputatio de Venæſectione, quatenus Motum Sanguinis mutat," ibid. 1729.—"Diſſertation ſur la Mechanique des Secretions dans le Corps Humain," Bourdeaux, 1746. This diſſertation obtained a prize from the academy of that city. We omit ſeveral tracts publiſhed between 1744 and 1754, in continuation of the Hallerian controverſy, and have only to notice his "Phyſiologia Medica, ſeu de Actionibus Corporis Humani Sani Doctrina," Jenæ 1751, 4to. cum fig.—"Elementa Phyſiologiæ Medicæ, &c." 1757, an abridgment of the preceding for ſtudents; and "Methodus Medendi Morbos, cum præfatione de præſtantia Theoriæ Hambergeri, præ ceteris," ibid. 1763, publiſhed by profeſſor Baldinger. Eloy. Dict. Gen. Biog.

HAMBOIS, *Dr.* JOHN, is ſaid to have poſſeſſed a conſiderable ſhare of learning in all the arts, and to have been no contemptible mathematician, but his biographers add, that muſic held the firſt place among all his ſtudies. It is related of him likewiſe, that he was remarkable for a fertile fancy, and a humour of a peculiar kind; and Pits, taking his ideas of muſical compoſition from a later period, tells us, that his knowledge in harmony, in the combination of concords, and preparation and reſolution of diſcords, was ſuch as no other perſon of his own age and nation poſſeſſed. To theſe talents, Hambois is allowed to have joined a great knowledge in the Latin tongue, in which he wrote a tract, entitled "Summum Artis Muſices;" and "Cautionum Artificialium diverſi generis," &c. Tanner was of opinion that this muſical treatiſe was the ſame as that in the Bodleian library, Digby 90, "De Quatuor Principalibus Muſicæ;" but that is proved to be the property of another. See SIMON TURNSTILE.

Whether Hambois was a member of the univerſity of Oxford

ford or Cambridge does not appear, nor indeed is it precisely known at what time he received his diploma.

In Hollinshed's Chronicle, p. 1355, there is an enumeration of the most eminent men of learning in the reign of Edward IV. among whom the author includes John Hambois, "an excellent musician," adding, that "for his notable cunning therein, he was made a Doctor of Music."

HAMBURGH, in *Geography*, a free imperial city of Germany, and one of the three cities of the Hanseatic league (see HANSE-*towns*), and, next to Vienna and Berlin, the most considerable in Germany, is situated in the circle of Lower Saxony, and in that part of Holstein which is called "Stormar," on the rivers Elbe, Alster, and Bille, about 60 miles from the influx of the Elbe into the ocean. The Elbe is here, including the islands, near a mile broad; and, on the other side of the city, the Alster forms a bason, about 1000 feet long, which is chiefly used by parties of pleasure, being furnished with a number of boats for their accommodation. Near this bason is a large broad place called the "Jung farnsteig," or Ladies walk, planted with rows of trees, and branching out into three distinct pleasant walks; and opposite to the Alster are some of the best houses in the city, which afford a charming prospect. The Elbe, besides forming two spacious harbours, runs through most parts of the city in canals, which being generally broad and deep, are very convenient for the merchants, whose houses are situated near them. The tide also contributes to their additional convenience by ebbing and flowing in these canals, as well as in the river itself, twice a day; though it is sometimes productive of inundations, which fill the lower buildings and cellars with water. The bridges that cross these canals are not fewer in number than 84; but many of them, forming the continuations of streets, and on the same level with them, are not visible. The city is divided into the *old*, which is the largest, the most crowded, and the most convenient for business, and the *new*, by one of the best streets in Hamburgh, called the "Neue-wall." There are some other streets, which are spacious and of good appearance; but the streets and lanes are for the most part narrow and dirty, and very much crowded with inhabitants, the extent of the city being by no means proportionate to its inhabitants. The houses have no external elegance to recommend them, and within, whatever recommendations they may afford, the admission of light is obstructed by the awkward disposition of their stair-cases. This city was fortified by Charlemagne, A.D. 808. But the fortifications are constructed in the old Dutch taste, with spacious ramparts, planted with trees, the circuit of which is about an easy two hours' walk, or, as some estimate them, about three miles. These ramparts are lofty and so broad, that several carriages may go abreast; the moats are deep and wide. The number of bastions round the town is 24, besides some out-works; particularly those called the "Sternchanze" and the "Neuewerk;" the latter is merely a line regularly fortified, and enclosing the streets, houses, and gardens, called by some the "Neuenwerk," or the "Suburb of St. George." The "*Hamburgh-Berg*" is a high land on the bank of the Elbe, between Hamburgh and Altona, and properly a suburb of the city. This suburb extends to Altona, and consists of a range of houses, with different docks, large warehouses for the manufacture of tar and whale oil, a hemp-magazine, a church, and an hospital for idiots and lunatics. The city has four principal gates, two smaller, and two water gates, called the "Upper" and "Lower Baum." All ships that go to or come from the sea, pass through the latter of these gates. The city-gates are shut in winter from the hour of four to eight, and in summer from seven to ten, and when once shut, they are never opened on any account till morning. As soon as the gates open in the morning, a multitude of boats and small barks appear, which are loaded with milk, fruit, and all kinds of provisions; and thus the markets are plentifully supplied chiefly from Hanover and Holstein; but provisions of every kind are dear. Those who will take the trouble to rise early and go to the banks of the Elbe, about two miles from the town, will obtain every article brought from Hanover and Holstein at less than half the price which it will fetch in the markets. To those who amuse themselves with this walk, the harbour of the Elbe exhibits a rich and varying prospect of vessels of every size, sailing up and down the river, and occupied in bringing provisions into the city or carrying back the produce. The public buildings at Hamburgh are the following churches; *viz.* St. Peter's near the Alster, St. Nicholas, St. Catharine's, St. Michael's, the Dome church, in which a fair is held for eight days preceding Christmas, and Johannes church, the English chapel, near the Exchange, in which service is performed every Sunday by an English clergyman. The palace of the imperial minister in the "Neue Wall" is a grand and beautiful building, and within it is a very neat Catholic chapel. In Admiralty street is a house for orphans, and an armoury. The city has also several hospitals and schools. In the Lombard, or town-pledge house, money is advanced on every kind of merchandize, without the intervention of a broker. The senate-house stands in the centre of the city, near the Exchange, and is joined by the Bank. Over the Exchange is the "Borsensaal," or Auction-room, where goods of every kind are daily brought to be sold from every quarter of the world. Hamburgh abounds also with hotels and taverns; and it has also a French and German theatre. The principal amusements of Hamburgh are music and dancing, card playing and billiards; in winter, riding upon sledges richly ornamented; and in summer, walking or riding to public gardens in the environs of the town. Hamburgh has been supposed to contain 100,000 inhabitants, or, according to the statement of Hoeck, 95,000, the principal of whom are opulent merchants; and many are foreigners and Jews. The government is aristocratic, and consists of a senate of 37 persons. Lutheranism is the established religion of the city, and the number of clergy, including those of the dependent territories, amount to 53. And though no other public exercise of religion is tolerated here, Calvinists and Papists may have an opportunity of attending worship at the chapels of the envoys of the emperor and other sovereigns, who reside in the city. Hamburgh has been usually reckoned the third commercial city in Europe; and it is undoubtedly the first in Germany. Formerly the principal occupation of the inhabitants consisted in brewing and the cloth manufacture; but at present the principal manufacture is the sugar-refinery, for which Hamburgh has long been famous. The cotton, stocking, gold thread, ribbon, and velvet manufactures of this place have been held in high estimation. The most considerable branches of its commerce have been linens, woollens, wine, sugar, coffee, spiceries, metals, tobacco, timber, leather, corn, dried fish, furs, &c.; and of late it has been the great mart of the British isles with the continent. Great quantities of all kinds of British goods have passed from hence to the different fairs, which are held three times every year at Frankfort on the Mayn, Frankfort on the Oder, Leipsic, and Brunswick. The merchants of Hamburgh have been in the habit of deriving great benefit from the specie bank, founded in 1619: this city has no paper-money except the bills of

exchange that paſs between individuals; the ſilver, not wanted for daily uſe, is depoſited in the cellars of the bank, ſecured with iron bars. The plan of this bank is ſaid to be very ſimple, and, on that account, commended. Each burgher has a right by inheritance to his folio on its books, in which the ſum is put down, that is at the ſame time depoſited in bars of pure ſilver. The amount of the ſum depoſited is ſet down in the folio; if there are 10,000 marks in the name of one perſon upon one folio, and as much upon another, and one pays 8000 marks to the other, the folio of the perſon paying is altered to that of 2000 marks, and that of the perſon paid to that of 18,000; this is called "writing off," and the ſame ſum remains in the bank, although ſtanding in conſequence of transfers, in different names. All marks here are called "marks banco," and average the value of 20*d.* Engliſh. Nothing is paid in but bullion or pure ſilver and gold, and it never diſcounts. In conſequence of this arrangement there can be no forgeries; no transfer can be made by bill, *i. e.* the party paying muſt attend in perſon; if ill and confined, he is attended by a clerk from the bank, if abroad, he muſt ſend a power of attorney, and the perſon receiving ſuch power, muſt be previouſly identified, before he can touch a ſhilling.

There is another part of the bank, where money may be paid in, and received back again, on drafts, as in the caſe of common bankers. The bank of Hamburgh has been regarded as one of the ſafeſt in Europe. The principal gold-coins in uſe here are the ducats, the Louis, and the Frederic d'or: the Daniſh ducat paſſes for 3*s.* The Engliſh and Dutch for 10*s.*; the Louis and Frederic d'or for 18*s.* The principal ſilver money is the two-mark piece, 2*s.* 3*d.* Engliſh, and the dollar, commonly called a ſpecie, which is 3 marks, 12 ſtivers, or 5*d.* Of ſilver money Hamburgh coins very large quantities. In Hamburgh there are numerous libraries, which do honour to the literary taſte of its inhabitants. The chief dependencies of this city are the river Alſter, the bailliage of Ham, ſome iſles and low-lands on the Elbe; and, beſides ſome diſtricts acquired from Holſtein, the bailliage of Ritzebuttel, on the N. of the duchy of Bremen, including the port of Cuxhaven, and the iſle called Neuewerk, ſituated oppoſite to that port. Towards the latter end of the year 1806, Hamburg was taken by the French. N. lat. 53° 36′. E. long. 9° 56′.

Hamburgh has long been remarkably active in the cultivation of muſical dramas or operas, and it ſeems by Matthe-ſon's liſt of them, in his Muſical Patriot, that the operas performed there, during the latter end of the 17th century, and the beginning of the laſt, exceeded in number thoſe of every other city in the German empire.

The firſt muſical drama, to be found in the annals of the Hamburgh ſtage, is "Orontes," ſet by the chapel-maſter, Theil, 1678; but this, and moſt of the operas performed here till the beginning of the preſent century, were in the German language.

The compoſitions of Keiſer, Mattheſon, Handel, and Telemann, who all began their career in this city, are the moſt renowned. See the biographical articles for theſe compoſers, in their ſeveral places.

A liſt of the numerous operas that were performed at Hamburgh after 1678, is recorded in Marpurg's Hiſtorical and Critical Eſſays on Muſical Subjects.

The principal compoſers of theſe early attempts at operas, during the latter part of the 17th century, were Strunck, Franck, Förtſch, Conradi, and Couſſer, who afterwards came to England, where he obtained the place of compoſer and maſter of the ſtate band of muſic in Ireland. In 1694, Keiſer, Brenner, and Krieger began to compoſe for the Hamburgh theatre, and in 1696 the operas of the celebrated Abate Steffani, which he had ſet in Italian for the court of Hanover, began to be tranſlated and performed in the German language at Hamburgh, except the airs, which were uſually ſung in Italian. This cuſtom prevailed in ſeveral parts of Germany ſo late as the year 1733, when Graun ſet his opera of "Pharao," the "Gianguir" of Apoſtolo Zeno, for the theatre at Brunſwic, of which only the recitatives were tranſlated into German, while the airs were ſet and ſung in their original language. See GRAUN.

In the beginning of the laſt century, according to Riccoboni, (General Hiſt. of the Stage,) the performers in the German operas at Hamburgh "were all tradeſmen or handicrafts; when your ſhoe-maker was often the firſt performer on the ſtage; and you might have bought fruit and ſweetmeats of the ſame girls whom the night before you ſaw in the character of Armida or Semiramis." This may, perhaps, have been literally true in the infancy of the muſical drama in that city; and even later, ſome of the under-characters may have been filled in the manner mentioned by Riccoboni; but afterwards, it is known that Mattheſon was many years a performer in thoſe operas; and the celebrated compoſer Haſſe, before he went to Italy, was a tenor ſinger on the Hamburg ſtage, in the operas of Keiſer. Life of Graun.

The celebrated Telemann, who ſucceeded Keiſer as muſic director in 1739, and died in 1767, in the 86th year of his age, was ſucceeded by the admirable Carl. Phil. Emanuel Bach, the greateſt muſician of his time, who died at above 80, in 1788.

HAMBURG, a ſmall poſt-town of America, in New Jerſey, 18 miles from Goſhen in New York.—Alſo, a handſome poſt-town, in Berke's county, Pennſylvania, on the E. ſide of Schuylkill, containing about 50 or 60 houſes, and a church for united Germans, Lutherans and Calviniſts; 70 miles N.N.W. from Philadelphia. N. lat 40° 34′. W. long. 76°.

HAMBURGHER's BAY, a bay on the W. coaſt of Spitzbergen. N. lat. 79° 23′. E. long. 9° 15′.

HAMDEN, a town in Hancock county, and ſtate of Maine, on the W. ſide of Penobſcot river, which is navigable to this town for veſſels of any ſize. This town has conſiderable trade; about 40 miles N.E. from Wincaſſet.—Alſo, a townſhip in New Haven county, Connecticut, about 8 miles N. of New Haven; containing 1482 inhabitants.

HAME-TREES, in *Rural Economy*, a term provincially employed to ſignify the hames of team horſes.

HAMED, EL, in *Geography*, a town of Egypt; 4 miles S. of Roſetta.

HAMEESE, a town of Algiers, 8 miles W.N.W. of Teffiſh; whence proceeds a river of the ſame name.

HAMEL DU MONCEAU, HENRY LEWIS DU, in *Biography*, an eminent French writer on rural economy ard vegetable phyſiology, was born at Paris in 1700. Being a member of the *Academie des Sciences*, he publiſhed in the memoirs of that body, in 1728, his firſt economical eſſay, on a kind of Paraſitical Fungus, which infeſts the roots of the Cultivated Saffron, and is ſo fatal to them, as to be known amongſt cultivators in France by the name of *Mort du Saffran*. This is the *Sclerotium crocorum* of Perſoon, *Fung.* 119; *Tuber paraſiticum* of Bulliard, *t.* 456. In the ſame year he publiſhed in that work his firſt treatiſe on a much more important ſubject, the propagation of trees by grafting, where he hazarded ſome phyſiological opinions, and entered

on a courſe of experiment and obſervation, ſubſequently purſued to an extent which has been of great ſervice to ſcience, and has juſtly rendered his name famous. He continued, from time to time, to communicate to the academy various papers relative to theſe matters. In 1750 he began to publiſh, in 12mo, his *Traité de la Culture des Terres*, which was continued in following years till 1761, when the ſixth volume came out. Our Engliſh writer Tull was his firſt guide, but he ſubſequently profited widely by the experience of himſelf and of various other people, aided by his phyſiological ſagacity, of which, it deſerves to be noted, he made a far more cautious uſe and application than is general with farming philoſophers. In ſhort, he left this moſt important practical ſcience in a ſtate far different indeed from that in which he found it, and deſerves to be reckoned the father of intelligent agriculture in France. His *Eléments d'Agriculture*, in two vols. 12mo publiſhed in 1764, may be conſidered as a ſequel to the preceding work. Theſe two volumes have been tranſlated into German, Spaniſh, and Engliſh. Du Hamel wrote alſo on the cultivation and preparation of Madder, in 4to. in 1757.

A more ſplendid and extenſive work of our author was publiſhed in 1755, making two vols. 4to. entitled *Traité des Arbres et Arbuſtes qui ſe cultivent en France en pleine terre.* Having been made inſpector of the Marine, the ſtudies which had been his amuſement, became, as he ſays, his duty; and while he undertook to inveſtigate all that concerned the cultivation and preſervation of timber, for that immediate object, he, in this work, extended his views to the treatment and botanical diſcrimination of all trees and ſhrubs capable of bearing the climate of France. Hence a number of American ſpecies became firſt known to his countrymen, and even to other nations, by his means. Haller reckons that this work treats of a thouſand ſpecies and varieties. They are arranged alphabetically, according to their Latin generic names, and he took for the baſis of the work the nomenclature of Tournefort. To this he was, in a manner, obliged by national prejudice in the time he wrote, but he has ventured to borrow ſome improvements from Linnæus, and he expreſſes himſelf with ſenſe and candour on this ſubject, as well as on that of botanical ſyſtems. To each genus is prefixed a copper-plate of its parts of fructification, with diſſections, after the manner of Tournefort; then follow the generic characters in French. The ſpecies are enumerated by the appellations of Caſpar Bauhin, or ſome other author, in Latin and French, and general remarks on their culture, properties, and uſes are ſubjoined. One or more ſpecies is repreſented by wooden cuts, in the adjoining pages. Moſt of theſe were furniſhed by the very identical blocks of the fine Venetian editions of Matthiolus, which Du Hamel was ſo fortunate as to procure almoſt complete, and the deficiencies are ſupplied by new cuts, of a far inferior ſtyle indeed, but very often of conſiderable merit. The economical remarks on the more important genera, as *Morus*, *Olea*, *Pinus*, and *Quercus*, are extenſive and valuable. It is to be regretted that the author did not regularly adopt the Linnæan nomenclature, as to ſpecies, which had appeared two years before in the *Species Plantarum*, a work he occaſionally cites; but he was not enough of a practical botaniſt to feel its tranſcendent utility. He would not, like Haller, have rejected it from prejudice or envy, for his character was far above ſuch feelings, from which his own modeſty ſecured him, and he was always in amicable correſpondence with the illuſtrious Swede, to whom he ſent his publications as they came out. We have now before us a copy, with his own hand-writing addreſſed to Linnæus, of his moſt eminent and important work, the *Phyſique des Arbres*, which came out in 1758, in two vols. 4to., with numerous copper-plates. On this his merit as a phyſiologiſt ſecurely reſts. In it he has collected and reviſed all that had been done before him, eſpecially by Malpighi, Grew, Hales, and Bonnet, as well as his own preceding experiments and remarks. We paſs over his preliminary obſervations on ſyſtem and nomenclature, in which the difficulties of the ſubject are more apparent than its advancement. They are however the performance of an intelligent and candid man, and he gives due credit to ſuch as deſerve it, whether his own countrymen or not. The great merit of this work conſiſts in its details reſpecting the ſtructure and anatomy of plants, and the phyſiology of their different organs. If Duhamel, like every body elſe till very lately, miſtook the woody fibres for the ſap-veſſels, he has formed very juſt conceptions of vegetable ſecretions, the production of the wood, the uſe of the leaves, &c. See CIRCULATION *of Sap*, and CORTEX.

In 1760 he publiſhed another valuable practical volume in 4to. with plates, entitled *Des Semis et Plantations des Arbres, et de leur Culture.* This had an eſpecial view to the great national object of improving the foreſts of the kingdom, highly important in a country where ſo much wood is continually uſed for fuel, and ſo little, in proportion to ſome other countries, naturally produced. The author laudably takes advantage of the panic, with which his countrymen are every now and then ſeized, of a ſcarcity of fuel, to excite their attention to the means he would recommend for the prevention of ſo dreadful an evil, and his book is a mine of practical information for the woodman, the planter, and the gardener, of the firſt authority and value.

The ſame ſubject is followed up in two vols. 4to. publiſhed in 1764, under the title of *De l'exploitation des bois, ou moyen de tirer parti des taillis demi futayes et hautes futayes.*

In 1767 appeared another 4to. volume, *Du tranſport, de la conſervation, et de la force du bois*, full of practical information relative to the properties, qualities, and uſes of different woods, intermixed with phyſiological remarks, as in the preceding performances of this excellent writer, who publiſhed alſo, in 1764, upon the art of refining ſugar, in folio, and, in 1765, on the preſervation of grain, in 12mo.

His moſt ſplendid work was printed at Paris in 1768, in two vols. 4to. with fine coloured plates. Its title is *Traité des arbres fruitiers.* In this the varieties of fruit-trees are elegantly diſtinguiſhed, by figures and deſcriptions, and their treatment illuſtrated with the uſual ſcience of the author.

Du Hamel was aſſociated to the chief learned ſocieties of Europe, lived in high reſpect and eſteem, and died at Paris in 1782, when he was dean of the Academy of Sciences. Beſides the above works, he wrote on the management of rope-yards, and fiſheries, and on naval architecture.—Works of Du Hamel. Haller. Bibl. Bot. Aikin's Gen. Biog.

HAMELBURG, in *Geography*, a town of Germany, in the biſhopric of Fulda; 24 miles S. of Fulda.

HAMELING, or HAM-*ſtringing*, the act of cutting the great tendon, vulgarly called the *ham-ſtring*.

Hameling or *hambling* of dogs, amounts to the ſame with *expeditation* or lawing.

HAMELLIA, in *Botany*, ſo named by Jacquin, in honour of the great vegetable phyſiologiſt Henry Lewis Du Hamel du Monceau; ſee that article. Jacquin by miſtake calls him John Baptiſt, and he ſpells the name of the genus with one *l*, in which he is followed by Juſſieu and others. In ſpite of theſe authorities, we preſume to think Linnæus the moſt correct, a double *l* being neceſſary to preſerve the ſhortneſs of the preceding vowel, as is juſtified by Latin analogy.—Linn. Gen. 93. Jacq. Amer. 71. Schreb. 123. Willd. Sp. Pl. v. 1. 980. Mart. Mill. Dict. v. 2.

Ait.

Ait. Hort. Kew. ed. 2. v. 1. 375. Juſſ. 207. Lamarck Dict. v. 3. 68. Illuſtr. t. 155. Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceæ*, Juſſ.—Linnæus reckons it doubtful, not having a comprehenſive idea of this order.

Gen. Ch. *Cal.* Perianth ſuperior, ſmall, in five deep, upright, acute, permanent ſegments or teeth. *Cor.* of one petal; tube cylindrical, with five angles, often ſwelling upwards; limb in five deep, equal, ſmall, acute ſegments. *Stam.* Filaments five, awl-ſhaped, inſerted into the tube; anthers vertical, long, linear, included in the tube. *Piſt.* Germen inferior, ovate, with a conical apex; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma linear, obtuſe. *Peric.* Berry oval, of five cells, crowned with the calyx. *Seeds* numerous, roundiſh, compreſſed, very ſmall.

Eſſ. Ch. Corolla tubular, five-cleft. Berry inferior, with five cells and many ſeeds.

1. H. *patens*. Jacq. Amer. 72. t. 50. Linn. Sp. Pl. 246. Swartz. Obſ. 77. Sm. Exot. Bot. v. 1. 45. t. 24. (H. coccinea; Sw. Prod. 46. Periclymenum aliud arboreſcens, ramulis inflexis, flore corallino; Plum. Ic. 212. t. 218. f. 2.) —Cluſters terminal, downy. Leaves three together, ſoft and downy, eſpecially beneath.—Gathered by Jacquin, as well as by Swartz more recently, on the buſhy ſides of mountains in Hiſpaniola. The late lady Amelia Hume received a fine plant from Jamaica, which flowered abundantly in her ſtove in October 1796, making a very ſplendid appearance. It ſeems, however, to have been firſt introduced into this country by Houſton's bringing a plant to Miller, who mentions it in his dictionary, by the name of *Periclymenum verticillatum*, ed. 8. n. 3. Yet it found no place in the firſt edition of Hort. Kew. being probably loſt ſoon after its introduction. The *ſtem* is ſhrubby, about four feet high, with round ſpreading leafy branches, downy when young. *Leaves* three together, ſpreading, three inches long, on red downy ſtalks, elliptical, tapering at each end, entire, ſoft and pliable, veiny; ſlightly downy above, more ſo, and paler, beneath. Sometimes they are ſaid to ſtand four or five in a whorl. *Stipulas* tapering, between the foot-ſtalks. *Cluſters* terminal, compound, their ſtalks red, downy, three together, forked, each bearing many ſeſſile flowers, in two rows with a ſolitary flower between. The *calyx* is purpliſh red, downy, as well as the germen to which it is united. *Corolla* an inch long, ſcarlet, paler, or yellow, at the baſe. *Berry* black, the ſize of a pea.

Jacquin's *H. erecta* is deemed a mere variety.

2. H. *axillaris*. Swartz. Ind. Occ. v. 1. 443.—Nearly herbaceous. Cluſters from the forks of the ſtem. Flowers turned to one ſide. Leaves oppoſite, ſmooth.—Native of Jamaica and Hiſpaniola, in buſhy rocky places by the brinks of rivers, according to Dr. Swartz, from whom and Dr. Wright we have ſpecimens. The *ſtem* is two or three feet high, branching, ſmooth; the lower part only being ſhrubby, the reſt herbaceous. *Leaves* oppoſite only, not whorled, about two inches long, elliptical, pointed at each end, dark green, ſmooth. *Cluſters* from the forks of the upper part of the ſtem, ſurmounted by branches and leaves, nearly or quite ſmooth. *Flowers* numerous, ſmall, pale yellow. *Berry* oval, crowned with the elongated, ſlightly recurved, calyx-teeth.

3. H. *chryſantha*. Swartz. Ind. Occ. v. 1. 444. Lamarck t. 155. f. 1. (Campanula minor fruteſcens, foliis ovatis oppoſitis ſtipulis acutis interpoſitis, capſulis quinquelocularibus; Browne Jam. 166. t. 14. f. 1.)—Cluſters terminal. Partial flower-ſtalks long and ſlender. Leaves oppoſite, obovato-lanceolate, pointed, very ſmooth.—Communicated by Dr. Swartz, who gathered it in mountain thickets on the weſt ſide of Jamaica. We cannot but think the ſynonyms of Plumier and Jacquin, quoted by him and copied by Willdenow under this ſpecies, are widely miſapplied, and that Browne's is the only true one. *H. chryſantha* is a *ſhrub* from four to ſix feet high, ſmooth in all its parts, and eſſentially diſtinguiſhed by the elongated ſlender ſtalks which ſupport each flower. The *corolla* is almoſt of a cylindrical figure, ſcarcely inflated, and near an inch long; its colour a ſhining yellowiſh orange. *Berry* bright ſcarlet. The *leaves* are uſually broadeſt beyond their middle.

4. H. *lutea*. Von Rohr. MSS. (H. chryſantha; Jacq. Coll. v. 3. 204. Ic. Rar. t. 335.)—Cluſters terminal, divaricated, recurved. Flowers nearly ſeſſile. Tube inflated. Leaves oppoſite, elliptic-lanceolate, pointed, ſmooth.—Gathered by Von Rohr in Cayenne, and by Mærter, who, though never mentioned by Jacquin, ſent this and abundance of fine plants from the Caraccas. It flowered in the Vienna ſtove all ſummer long, ripening its black berries in October. The *ſtem* is ſhrubby, very ſmooth. *Leaves* two inches or more in length, broad in the middle, tapering much at each end, quite ſmooth, except a little occaſional down where their veins branch from the midrib. *Footſtalks* red and rather long. *Cluſters* ſmooth, or ſlightly downy. *Flowers* numerous, ſpreading every way, nearly ſeſſile, yellow, their *corolla* rather above half an inch long, the tube dilated ſuddenly juſt above the baſe, ſo as to be almoſt bell-ſhaped. This dilatation ſeems to contract ſomewhat in drying. No ſpecies can be more diſtinct than this is from the laſt.

5. H. *ventricoſa*. Swartz. Ind. Occ. v. 1. 446. (Nerio affinis arbor, verſicolora materie, lauri folio lucido, flore pentapetaloide ſulphureo amplo; Sloane Jam. v. 2. 63. t. 183. f. 2? Periclymenum arboreſcens, ramulis inflexis, flore luteo; Plum. Ic. 212. t. 208. f. 1? Campanula arboreſcens, &c.; Browne Jam. 166. n. 1.)—Cluſters terminal or axillary, ſpreading. Flowers on ſhort ſtalks. Tube inflated. Leaves three together, elliptical, pointed, ſmooth.—Native of dry ſhrubby hills in Jamaica. A large *ſhrub* or ſmall *tree*, according to Swartz. Sloane ſays it is "a very large and ſtately *tree*, affording very broad boards to make tables or cabinets, the wood being of the ſoftneſs or grain of elm," marked with wavy light brown or grey lines; and that it is called "Spaniſh elm, or Prince wood, being imported to Europe in great quantities for the uſe of cabinet-makers." We preſume it is the grey ſattin-wood, but nothing is more ill explained than theſe exotic articles of commerce. Sloane's plant may very poſſibly be diſtinct from Swartz's, for his figure by no means anſwers well to our ſpecimens, though too bad to afford any ſolid marks of difference. Swartz's ſpecimen is ſo like Plumier's figure, that we have preſumed to remove his ſynonym hither, as it can moſt aſſuredly have nothing to do with *H. chryſantha*. The *branches* of Dr. Swartz's plant are ſmooth. *Leaves* three together, broadly elliptical, tapering at each end, with more or leſs of an elongated point; they are from two or three to four or five inches long, and one or almoſt two broad, ſmooth, ribbed, and veiny, moſtly red-edged. *Footſtalks* half an inch to an inch long. *Stipulas* ovate, pointed, incurved. Swartz deſcribes them "in pairs" and "awl-ſhaped;" we find them ſolitary in his ſpecimen. The *cluſters* are moſtly terminal, though occaſionally ſurmounted by branches, many-flowered, three-branched, ſpreading nearly or quite ſmooth. *Flowers* nearly ſeſſile, or on ſhort partial ſtalks, leaning to one ſide, and ſomewhat drooping. *Calyx-teeth* ſhort, and broad at the baſe. *Corolla* yellow, an inch and quarter long, its tube contracted juſt above the bottom, then ſuddenly dilated, or nearly bell-ſhaped, as in the laſt, but, like that, ſhrunk in when dry. *Berry* ſcarlet.

6. H.

6. H. *grandiflora*. Saliſb. Parad. t. 55. L'Herit. Sert. Angl. 4. t. 7?—Cluſters terminal or axillary. Flowers few, on longiſh ſtalks. Tube inflated. Leaves three together, lanceolate, acute, nearly ſmooth.—Native of the Weſt Indies. We received it in Auguſt, 1791, from the earl of Tankerville's ſtove at Walton upon Thames. In ſeparating this from the laſt, we rather wiſh to direct the attention of botaniſts to the ſubject, than abſolutely to decide; but it appears to us that the ſpecies of this beautiful genus are ſtill open to correction, and yet we are not furniſhed with ſufficient materials to elucidate the whole, they being very rare in gardens, and even in herbariums. The *leaves* of the preſent ſpecies are either three or four in a whorl, on longiſh ſtalks, elliptic-lanceolate, three inches long, hardly an inch wide, acute, ſlightly downy towards the edge, with far leſs conſpicuous lateral veins than in *H. ventricoſa*. In our ſpecimen the inſertion of the leaves ſeems to be, by ſome accident of its growth, for we have ſeen no other ſo, diſturbed into a ſpiral direction. The *ſtipulas* are in pairs betwixt every leaf-ſtalk, and awl-ſhaped, as repreſented in the *Paradiſus Londinenſis*, not broad and ſolitary as in L'Heritier, or in our ſpecimens of the foregoing ſpecies. The *flowers* alſo are much fewer in the cluſter, more inflated, and ſupported by much longer and ſlenderer partial ſtalks than in the laſt, which circumſtances, and eſpecially the double ſtipulas, have induced us to ſeparate the two, with a mark of doubt as to L'Heritier's ſynonym, chiefly on account of his delineation of the ſtipulas. The *corolla* is of a fine golden yellow, with a ſpreading border; the tube even, not angular.

7. H? *ſeſſiliflora*. Willd. n. 5. (H. glabra; Lamarck. Dict. v. 3. 69. Amaioua guianenſis; Aubl. Guian. v. 2. ſuppl. 13. t. 375.)—Flowers terminal, capitate. Leaves three together, elliptic-lanceolate, pointed, ſmooth.—Gathered by Aublet in the wild foreſts of Guiana, bearing fruit in May. Of the *flowers* he ſaw nothing, and the capitate inflorescence is certainly very much againſt its belonging to this genus, though the habit is tolerably like. The *trunk* of the ſhrub is four feet or more in height, and five or ſix inches thick, with a reddiſh bark and white wood. *Branches* ſeveral, ſtraight, triangular, knotty, ſix or ſeven feet long. *Leaves* three together, ſometimes eight inches long, and three or three and half broad, taper-pointed, ſtalked, firm, ſmooth. *Stipulas* annular, fringed. *Fruit* oval, angular, yellow, eaten by the armadillos. The *ſtipulation* of this ſhrub ſeems to indicate a different tribe of the *Rubiaceæ* from *Hamellia*. S.

HAMELN, in *Geography*, a town of Weſtphalia, and capital of the principalty of Calenberg, to which it gives name, ſituated on the Weſer, which here forms an iſland, and is furniſhed with a ſluice for the convenience of ſhipping. It derives its name from the river Hamel, which here joins the Weſer. The town contains 600 houſes of merchants and tradeſmen, with 50 eccleſiaſtical and other ſplendid buildings, among which are two churches. The magiſtrates poſſeſs civil and criminal juriſdiction. In November 1806 it ſurrendered to the French; 18 miles S. W. of Hanover. N. lat. 52° 5'. E. long. 9° 18'.

HAMEN, El, a town of the Arabian Irak; 140 miles W.S.W. of Baſſora.

HAMES, the name of the iron or wooden harneſs by which draught horſes are attached to the carts or other ſorts of farming carriages.

HAMETNAGUR, in *Geography*, a town of Hindooſtan, in Cude; 34 miles N. W. of Kairabad.

HAMFARE, in our *Old Writers*, a breach of the peace in a houſe.

HA-MI, Chemi, or *Chamel*, in *Geography*, a country of Aſia, ſituated to the N. E. of China, at the extremity of that deſert which the Chineſe call "Cha-mo," and the Tartars "Cobi." (See Cobi.) It is only 90 leagues diſtant from the moſt weſterly point of the province of Chen-ſi, and by the maps of the Jeſuits, 70 leagues from the Chineſe wall; whereas Goez ſays, that he travelled the ſpace in nine days, which can ſcarcely equal that length, as 30 miles a day ſeems too much for a caravan, eſpecially when we conſider that 20 days are occupied in travelling from Chaliſh to Purhan, not far from Turfan, a ſpace which in our maps does not occupy above half the extent between Ha-mi and the Chineſe wall. This country in the early ages was inhabited by a wandering people, named "Iong." About the year 950 B. C. they ſent deputies to pay homage to the emperor of China, and preſented ſome fabres by way of tribute. Theſe people, not having received timely aſſiſtance, fell under the dominion of the "Hiong-nou," who appear to have been the ſame as the Huns, and who at that time were a formidable nation. The Chineſe ſeveral times loſt and recovered the country. After ſeveral changes and revolutions, the Mahometans, who had made a rapid progreſs in all the countries that are ſituated between Perſia, Cobi, and the Caſpian ſea, advanced as far as Ha-mi, which they conquered. Afterwards it had princes of its own, but dependent on the Tartars, who ſucceſſively ruled theſe immenſe regions. The Yuen, or Mogul Tartars, again united the country of Ha-mi to the province of Chen-ſi; and this union ſubſiſted till the year 1360, when the emperor formed it into a kingdom, ſtipulating that its princes ſhould do homage and pay tribute. Several viciſſitudes afterwards occurred; however, the prince who occupied the throne in 1696, acknowledged himſelf a vaſſal of the empire, and ſent as tribute to Pekin, camels, horſes, and fabres. Kang-hi having received his homage with the uſual ceremonies, publiſhed a diploma, which eſtabliſhed the rank to be held by the king of Ha-mi among the tributary princes, the time when homage ſhould be rendered, the preſents neceſſary for his tribute, the number of auxiliaries which he was bound to furniſh in time of war, and the manner of his appointing a ſucceſſor.

This country, though ſurrounded with deſerts, is reckoned one of the moſt delightful in the world. The ſoil produces abundance of grain, fruits, leguminous plants, and paſture of every kind. The rice which grows here is particularly eſteemed in China; and its pomegranates, oranges, peaches, raiſins, and prunes have a moſt exquiſite taſte; and even the jujubes are ſo juicy, and have a flavour ſo delicious, that the Chineſe call them "perfumed jujubes." The melons are much valued, and are carried to Pe-king, for the emperor's table; and they have this ſingular property, that they may be kept freſh during great part of the winter. But the moſt eſteemed productions of this country are its dried raiſins, which are of two kinds. The firſt reſemble thoſe known in Europe by the name of Corinthian, the ſecond are ſmaller and more delicate than thoſe of Provence. Theſe raiſins are preſcribed in various diſorders. An infuſion of the firſt is ſaid to facilitate an eruption of the ſmall-pox about the fourth day, and to promote a gentle perſpiration in ſome kinds of pleuriſies, or malignant fevers. Althoug Ha-mi lies farther towards the north than ſeveral provinces of France (*viz.* N. lat. 42° 53' 20"), we are nevertheleſs aſſured, that its climate is more favourable to the culture of vines, and that the grapes have a ſuperior quality. It never rains at Ha-mi; dew and fogs are ſcarcely ever ſeen here; the country is only watered by the ſnow which falls in winter, and this ſnow is collected at the bottoms of the mountains, and carefully preſerved. The king-

dom of Ha-mi contains a great number of villages and hamlets, but it has properly only one city, which is its capital, of the ſame name. It is ſurrounded by lofty walls, half a league in circumference; and it has two gates, one fronting the eaſt and the other the weſt. Theſe gates are exceedingly beautiful, and make a fine appearance at a diſtance. The ſtreets are ſtraight and well laid out; but the houſes, which contain only a ground-floor, and which are almoſt all conſtructed of earth, make very little ſhow; however, as this city enjoys a ſerene ſky, and is ſituated in a beautiful plain, watered by a river, and ſurrounded by mountains, which ſhelter it from the north winds, it is a moſt delightful reſidence. On whatever ſide it is approached, it has gardens, which contain every thing which a fertile and cultivated country can produce in the mildeſt climates. All the ſurrounding fields are enchanting, but they do not extend far, as they terminate in dry plains, where a number of beautiful horſes is fed, and alſo a ſpecies of excellent ſheep, with large flat tails, ſome of which weigh three pounds. Ha-mi abounds in foſſils and valuable minerals. The Chineſe have, for a long time, procured diamonds and a great quantity of gold from it; at preſent it ſupplies them with agate, which they highly value. As to the inhabitants of this ſmall ſtate, they are brave, capable of enduring fatigue, very dexterous in all bodily exerciſes, and are excellent ſoldiers, but they are fickle, and ſoon irritated; and when in a paſſion, they are extremely ferocious and ſanguinary. Du Halde places Ha-mi in N. lat. 42° 53'. W. long. from Pe-king 22° 23'. Du Halde. Groſier.

HAMILCAR, Barcas, in *Biography*, father to the celebrated Hannibal, a Carthaginian general, was in Sicily during the firſt Punic war, and after a peace had been made with the Romans, he quelled a rebellion of ſlaves, who had taken many African towns, and had laid ſiege to Carthage itſelf. This internal war was concluded by the almoſt total deſtruction of the enemy: and the towns which had eſpouſed their cauſe, or which had ſubmitted to their power, were obliged to ſurrender to the arms of Hamilcar. He now meditated ſomething more important for his country, and extended the dominion of the republic beyond its former limits in Africa, and brought the whole country to a tranquil condition. After this he paſſed into Spain with his ſon Hannibal, whom he cauſed to ſwear at the altar eternal and irreconcileable enmity againſt the Romans, a paſſion by which he himſelf had ever been animated. In Spain he carried on a war for nine years, with great ſucceſs, ſubduing many nations, and enriching his army and country with abundance of plunder. In this expedition he laid the foundation of the city of Barcelona. Univer. Hiſt.

HAMILTON, Anthony, *Count of*, deſcended from a younger branch of the dukes of Hamilton, was born in Ireland about 1646. His mother was ſiſter to the duke of Ormond, viceroy of that iſland. The troubles in which the country was involved drove his family to France while he was an infant, and he was educated in the religion and language of the country. During the reign of Charles II. he made ſeveral viſits to England, but his religion prevented him from obtaining any public employment here. James II. however, gave the count Hamilton a regiment of infantry in Ireland, and raiſed him to the important poſt of governor of Limerick, but when James abdicated the throne, the count thought it prudent to accompany him back to France, where he ended his days. He died at the age of ſeventy-four, and his works were printed collectively in ſix volumes 12mo. in the year 1749. They conſiſt of "Poems," "Fairy Tales," and of the "Memoirs of count Grammond." This laſt, according to Voltaire, is of all books that in which the moſt ſlender ground work is ſet off with the gayeſt, moſt lively, and agreeable ſtyle. "The hero," ſays his biographer, "is little more than a genteel ſharper; and the adventures which befal him are the common ones of ſuch a character; but they are related with irreſiſtible pleaſantry, and all the grace of faſhionable converſation." The work is filled with portraits and anecdotes of the moſt celebrated perſons in the court of Charles II., which has rendered it peculiarly intereſting to Engliſh readers. Moreri.

Hamilton, Gavin, a painter of hiſtory, deſcended from a branch of a noble family in Scotland, who reſided the greater part of his life at Rome. He had not, perhaps, the genius of an inventor; but the advantages of a liberal education, of a claſſic taſte in the choice of his ſubjects, and the ſtyle at which he always aimed, made him, at leaſt, equal to his moſt celebrated contemporaries. Some of the ſubjects which he painted from the Iliad bear ample teſtimony to this. Achilles graſping the dead body of Patroclus, and rejecting the conſolation of the Grecian chiefs, and Hector tied to his chariot, have ſomething of Homeric ſimplicity and pathos. His expreſſions, however, are not always juſt. In his Achilles diſmiſſing Briſeis, the geſticulation of an actor ſupplants the expreſſion of the man.

Of his women, the Briſeis in the ſame ſubject is the moſt attractive. Neither his Andromache mourning over Hector, nor the Helen of the ſame; or the ſcene with Paris, reach our ideas of the dignity and anguiſh of the former, or the forms and graces of the latter. Indeed, what idea can be ſuppoſed to reach that beauty, which, in the confeſſion of age itſelf, deſerved the ten years' ſtruggle of two nations? and yet, in the ſubject of Paris, thoſe graces, and that form, are to be ſubordinate to the ſuperior ones of Venus. He would rank with the firſt names in art, who from ſuch a combination ſhould eſcape without having provoked the indignation, contempt, or pity of diſappointed expectation.

Though he was familiar with the antique, the forms of Hamilton have neither its correctneſs nor characteriſtic purity: ſomething of the modern eclectic principle prevails in his works, and his compoſition is not ſeldom as much beholden to common-place, ornamental conceits, and habits, as to propriety. Though ſolicitous about colour, he was no colouriſt; he ſhould have diſdained what the grandeur of his ſubjects rejected, and contented himſelf with negative hues, and grave and ſimple tones.

A conſiderable part of the latter period of this artiſt's life was dedicated to the diſcovery of antique monuments. He made excavations and opened buried chambers in various places of the Roman ſtate, Centumcellæ, Velletri, Oſtia, and above all at Tivoli, among the ruins of Adrian's Villa; and it muſt be acknowledged that the ſucceſs which attended moſt of his reſearches, made ample amends to the art in general, for the loſs which painting may have ſuffered by the intermiſſion of his practice and example. In the collection of the Muſeo Clementino, next to the treaſures of the Belvidere, the contributions of Hamilton in ſtatues, buſts, and baſſo relievo, were by far the moſt important to the progreſs of arts and claſſic learning; and the beſt collections ſcattered over Ruſſia, Germany, and this country owe many of their principal ornaments to his diſcoveries. Nor was he leſs attentive to modern art; he publiſhed his "Schola Italica Picturæ," to trace the progreſs of its ſtyles from Leonardo da Vinci to the ſucceſſors of the Caracci.

It yet remains to be ſaid of Hamilton, that however eminent his talents, or other qualities were, they were ex-

ceiled

celled by the liberality, benevolence, and humanity of his character. He died in 1794. Fuſeli's Pilkington.

HAMILTON, WILLIAM, a painter of hiſtorical and fancy ſubjects: he was of Scotch extraction, but probably born in London, and went, when ſcarcely a youth, with Zucchi, the arabeſque ornamental painter, to Rome. At his return he ſoon acquired general employment by the verſatility of his talents, the amenity of his method, his knowledge of colours, his aſſiduity and expertneſs. Though he was employed in all the public works which the ſpeculations of commerce had contrived to form a new ſource of opulence from the talents of living artiſts, as in the Shakeſpeare, the poets and biblical galleries, and that of national hiſtory; and in each of them obtained the praiſe of his employers, and the applauſe of the public; yet his choice of ſtyle is too vague in drawing, execution, and expreſſion, to obtain the meed of exalted praiſe from the true connoiſſeur. To pleaſe the eye appears to have been more his object than to inform the mind; and ornament, rather than truth, captivated his imagination. In works of mere ornament he excelled, and gave to it propriety, richneſs, and a claſſic air. His coloured drawings imitate the fulneſs of his oil paintings with more freſhneſs, and without much labour are finiſhed with taſte. Hamilton was a member of the Royal Academy; was poſſeſſed of affability and gentle manners; and died univerſally lamented, in 1801, at the age of fifty.

HAMILTON's *Bawn*, in *Geography*, a ſmall fair town in the barony of Fews, county of Armagh, and province of Ulſter, Ireland, about two miles ſouth from Rich-hill, and 61 N. by W. from Dublin. It is a well built town, on the ſpot recorded under this name in the poetical works of dean Swift.

HAMILTON, the chief town of the middle ward of Lanarkſhire, in Scotland, pleaſantly ſituated on the banks of the rivers Clyde and Evan near their confluence. The ſituation of Hamilton is extremely pleaſant, and the ſurrounding country level, fertile, and richly cultivated. It is of no great conſequence as a place of trade, the only manufactures cultivated here being thoſe of weaving and figuring muſlins, and thoſe employed in theſe branches almoſt univerſally work for the manufacturers of Glaſgow, from which it is about eleven miles diſtant. The ducal reſidence, or, as it is generally called, the palace, is a large building, by no means remarkable for its architecture, but commodious and ſplendidly furniſhed. It contains a fine gallery of paintings, many of which are originals of eminent maſters. A Daniel in the Den of Lions, by Reubens, is greatly admired by connoiſſeurs. The pleaſure grounds are very extenſive, and during the life of the late duke, who was very much attached to equeſtrian and other athletic amuſements, there were horſe-races annually, but ſince his death this practice is diſcontinued. Near Hamilton is the village and bridge of Bothwell, famous in Scottiſh hiſtory for the defeat of the Covenanters, in the reign of Charles II. Near the village of Bothwwell, upon the banks of the Clyde, is Bothwell caſtle, one of the ſeats and the chief reſidence of lord Douglas, of Douglas. Situated on a winding part of this noble river, with precipitous banks, richly covered with wood and ſhrubby, the pleaſure grounds of Bothwell are delightful. The ancient caſtle, from which the huſband of the unfortunate Mary Stewart derived his title, is in ruins.

HAMILTON, a poſt-town of America, in Eſſex county, Maſſachuſetts; 26 miles N.E. from Boſton, containing 749 inhabitants.—Alſo, three townſhips in Pennſylvania; one in each of the counties of York, Franklin, and Northampton.—Alſo, a poſt-town in Chenango county, New York, containing 2673 inhabitants.—Alſo, a town in Albany county, New York, ſo called in honour of Alexander Hamilton, eſq. a great patron of American manufacture; 10 miles W. of Albany: famous for its glaſs manufactory. The air is highly ſalubrious.—Alſo, a county in the ſtate of Ohio, bounded N. on Warren and Buller counties, S. on the Ohio; E. on Clermont and Warren; and W. on the State line or Indiana. Its towns are Cincinnati and Columbia. It is ſaid to contain 14,692 inhabitants.—Alſo, a port in the Bermuda iſlands.—Alſo, a cape on the N. coaſt of Newfoundland iſland.—Alſo, a ſettlement in Vermont, on the Canada line.

HAMILTON *Ban*, a townſhip of Adam's county, Pennſylvania. In a mountain, on the W. part of the town, are found gold, ſilver, copper, and iron.

HAMILTON *Diſtrict*, deriving its name from A. Hamilton, eſq. is ſituated in the ſtate of Teneſſee, on the waters of the Holſton and Clinch, bounded S. by Teneſſee river, and ſeparated from Mero diſtrict on the W. by an uninhabited country. It contains the counties of Knox, Jefferſon, Blount, Seveer, Grainger, and Coche, and has 37,836 inhabitants, of whom 2996 are ſlaves.

HAMILTON *Fort*, a blockaded fort which ſtands on the E. ſide of the Great Miami, in the ſtate of Ohio, 25 miles S. of fort St. Clair, and 25 N. of Cincinnati. It is capable of containing 200 men. The ſoil near it is rich.

HAMILTON *Townſhip*, a townſhip in the county of Northumberland, Upper Canada, lying W. of Haldimand, with lake Ontario in front, and Rice lake in the rear.

HAMIN, a town of Arabia Felix, in the province of Oman.

HAMING, a town of Sweden, in Sudermanland; 10 miles S. of Stockholm.

HAMLET, a diminutive of *ham*, ſignifies a little village, or rather a part of a village.

Spelman, upon theſe words, ſhewing the difference between *villa integra* and *villa dimidia & hamleta*, ſays, "Hamleta vero, quæ medietatem friborgianon obtinuit hoc eſt ubi quinque capitales plegii non deprehenſi ſint." The ſtatute of Exon. 14 Edw. I. mentions this word thus, "Les nommes de toutes les villes et hamlets que ſont en ſon wapentake." In the ancient MS. hamlet is expounded the ſeat of a freeholder.

HAMM, in *Geography*, a town of Germany, the capital of the county of Mark; large, well built, ſurrounded with ditches and palliſades. In this town the Calviniſts have an academy with three profeſſors, a Latin ſchool, and a pariſh church. The Lutherans have a church, and the Roman Catholics a convent. It is a place of good trade, and was formerly Hanſeatic. Its linen bleacheries are extenſive; 17 miles S. of Munſter. N. lat. 51° 40'. E. long. 7° 53'.

HAMMA, ἁμμα, of ἅπτω, *I tie*, a word uſed, by ſome chirurgical writers, for a knot that faſtens a bandage.

HAMMACÆ, or HAMMOCK *Racks*, are the battins nailed to the ſide of the beams, to which the ſailors hang their hammocks.

HAMMAH, EL, or ELHAMMAH *of Gabs*, in *Geography*, a town of Affica, in Tunis, lies four leagues to the weſtward of Gabs, being one of the frontier towns of the Tuniſcens, where they have a ſmall caſtle and garriſon. The old town, at a little diſtance, was anciently called "Aquæ Tacapitanæ," on account of its baths. Theſe baths are ſheltered from the weather by low thatched hovels, and their baſons, about 12 feet ſquare and four deep, have, a little below the ſurface of the water, ſome benches of ſtone for the bathers to ſit upon. One of theſe baths is called the "Bath of the Lepers," below which the water ſtagnates and forms a pool, called the

"Lake of the Lepers." A ſmall rivulet is formed by the water which flows from theſe baths, which, after having been conducted in a number of ſmall ſtreams through the adjacent gardens, becomes united, and directs its courſe towards the "Lake of Marks," and loſes itſelf in the ſand. Shaw's Travels, p. 128.

HAMMAM LEEF, a town of Africa, in Tunis, having a celebrated hot bath, much reſorted to by the inhabitants of the capital, and near it is a mountain rich in lead-ore; 14 miles S. of Tunis.

HAMMAM *Mereega*. See MEREEGA.

HAMMAM *Meſkonteen*, a town of Africa, in Algiers; 36 miles E. of Conſtantina.

HAMMAMLU, a town of Aſiatic Turkey, in Natolia; 36 miles W. of Alphiom-Karahiſar.

HAMME, a town of France, in the department of the Scheldt, and chief place of a canton, in the diſtrict of Termonde. The place contains 7238, and the canton 14,251 inhabitants, on a territory of 50 kiliometres, in four communes.

HAMMEL's TOWN, a town of America, in Dauphiné county, Pennſylvania, five miles from Suſquehannah river, and 85 from Philadelphia, containing a German church, and about 35 dwelling-houſes.

HAMMER, an inſtrument of iron, with a handle of wood; uſed, in moſt mechanic arts, to beat, ſtretch, drive, &c. Bodies capable of being ſtretched or extended under the hammer, are ſaid to be *malleable*.

The Latins call it *malleus*, anciently *martulus* or *marculus*; by which name Pliny calls it when he ſays that Cyntra, ſon of Agrippa, invented the hammer and pincers. Hiſt. Nat. lib. vii. cap. 56. Vide Hardouin. Not. ad loc.

The hammers of our great forges are moved or worked by a water-mill.

HAMMER, in the *Manege*. See SHOEING-*hammer*.

HAMMER *of a Clock*. See CLOCK.

HAMMER, in *Anatomy*. See MALLEUS and EAR.

HAMMER-*headed ſhark*. See SHARK.

HAMMER, *Yellow*, in *Ornithology*. See EMBERIZA *Citrinella*.

HAMMER-*hardened*, in *Smithery*, is ſaid of iron which is ſhort or brittle, owing to its having been hammered when in a warm or due red heat, which is ſuppoſed to cloſe its pores. Hammer-hardened iron, by being heated to a white heat, and ſuffered to cool gradually, again recovers its toughneſs. See HARDENING.

HAMMER-*men*, or *Drivers*, in *Mining*, are thoſe colliers who fall or wedge down the coals in a coal-pit, after the holers have undermined them, the proceſſes of which are deſcribed in Mr. Farey's Report on Derbyſhire, vol. i.

HAMMER-*mills*, or *Forges*, in the *Iron Manufacture*, are works in which very large tilt and forge hammers, worked by water-wheels or by ſteam engines, are uſed for working the iron, and drawing it out into bars. Smaller hammers of the ſame kind are uſed now for forging the articles of various manufactures; in the ſcythe factories, theſe are called ſkelpers, and are very common in the neighbourhood of Sheffield. The hammer-mill uſed by Mr. George Walby, trowel-maker of Goſwell-ſtreet, is on a very curious conſtruction; a view and deſcription of which may be ſeen in the Tranſactions of the Society of Arts, vol. xxii. page 335.

HAMMER-*pick*, in *Mining*, is a ſtrong pick with a hammer at one end, almoſt like that uſed by paviors, which is uſed in coal-pits, by the remblers, or colliers, who break the coals into ſizable lumps, after they are fallen by the hammer-men, ready for the hurriers, or thoſe who drag them to the ſhaft bottom. The whole proceſs of working coals is deſcribed in Mr. Farey's Report on Derbyſhire, vol. i.

HAMMER, in *Geography*, a town of Norway, in the dioceſe of Aggerhuus; 14 miles N. of Chriſtiania.

HAMMER, *Little*, a town of Norway, in the dioceſe of Aggerhuus; 76 miles N. of Chriſtiania. N. lat. 61 9'. E. long. 10° 25'.

HAMMER *Iſland*, a ſmall iſland of Sweden, in the Baltic, near the coaſt of Blechingen; four miles E. of Carlſcrona.

HAMMERDALE, a town of Sweden, in the province of Jutland; 32 miles N.E. of Froſon.

HAMMERING, the act of beating or extending and faſhioning a body under the hammer.

When it is performed on iron heated for the purpoſe, the ſmiths uſually call it *forging*.

HAMMERING, in *Coining*. A piece of money, or a medal, is ſaid to be *hammered* when ſtruck, and the impreſſion given with a hammer and not with a mill.

For the method of beating with the hammer, ſee COINING.

HAMMERS *of Pythagoras*. See PYTHAGORAS, and HARMONICS.

HAMMERSCHMIDT, ANDREAS, in *Biography*, an eminent Lutheran eccleſiaſtical compoſer, born at Brixa, in Bohemia. Walter has given a long liſt of his publications, which are chiefly choral, and ſaid to have improved church muſic ſo much, that on his tomb-ſtone he is called "the glory of Germany." He died 1675, aged ſixty-four.

HAMMERSMITH, in *Geography*, a chapelry, or hamlet, in the pariſh of Fulham, hundred of Oſſulton, and county of Middleſex, contained, in the year 1801, 920 houſes, and 5600 inhabitants. During the interregnum it was propoſed to make this hamlet parochial, but the plan was not effected; and although the proportion has progreſſively augmented, yet the whole is dependent on a diſtant pariſh. The land of this hamlet is eſtimated at 1540 acres, nearly 300 of which are occupied by market-gardeners: the remainder is covered with houſes, incloſed in ſmall paddocks, and laid out in private gardens. The river Thames bounds the ſouthern ſide of this hamlet, and on the banks of that noble ſtream are many ſeats, villas, and rows of houſes. Among theſe is Brandenburgh houſe, which has been occupied by many diſtinguiſhed perſons. It is ſaid to have been built by ſir Nicholas Criſpe, about the beginning of king Charles the Firſt's reign. It was afterwards ſold to prince Rupert, as a reſidence for Margaret Hughes, an admired actreſs, who reſided here 10 years. George Doddington, afterwards lord Melcombe Regis, purchaſed it in 1748, and made conſiderable additions for the reception of ſtatues, antique pictures, &c. In the year 1792 the margrave of Brandenburgh-Anſpach bought it, and his lady, the margravine, rendered the houſe a ſcene of luxury and gaiety by the eſtabliſhment of a private theatre. The houſe is ſplendidly embelliſhed. Near the chapel, in the centre of Hammerſmith, is an ancient manſion called Butterwick-houſe, ſuppoſed to have been the reſidence of Edmund Sheffield, earl of Mulgrave, who died here in 1646. Near the houſe is a large cedar of Libanus, the girt of which, at three feet from the ground, is nearly eleven feet. The chapel was built in the time of king Charles I., and is ſaid to have coſt 2000*l.* although ſir Nicholas Criſpe gave the bricks. This gentleman is deſcribed as the inventor of the preſent mode of making bricks. (See Lloyd's Memoirs, page 623). At Hammerſmith are ſeveral other houſes, which have been occupied by diſtinguiſhed characters; but it would exceed our limits to notice

or deſcribe them. For further particulars the reader is referred to Lyſons's "Environs of London," vol. iv.

HAMMITES, in *Natural Hiſtory*, a name uſed by Pliny (Nat. Hiſt. l. 37. c. 10.) for a kind of ſtone compoſed of globules, reſembling pretty cloſely the ova of fiſhes, hence called alſo roe-ſtone, piſolithus, oalite, marmor, &c. by different writers. Dr. Woodward (Method of Foſ. p. 18.) ſeems to conſider the hammites as really produced from the roes of fiſhes, but thoſe who have more attentively conſidered the vaſt accumulation of theſe, in the Bath free-ſtone range, in all its courſe from Portland Iſland to Ketton, in Rutland, and thence into Yorkſhire, reject this opinion, and conſider theſe globules as a peculiar ſpecies of nodules.

HAMMOC, or HAMAC, a kind of hanging bed, ſuſpended between two trees, poſts, hooks, or the like; much uſed throughout the Weſt Indies, as alſo on board of ſhips.

The Indians hang their hammocs to trees, and thus ſecure themſelves from wild beaſts and inſects, which render lying on the ground there very dangerous.

The people of the Caribbee iſlands are wonderfully ſuperſtitious with regard to their hammocs, and do not make them without many ceremonies.

According to F. Plumier, who has often made uſe of the hammoc in the Indies, it conſiſts of a large ſtrong coverlet or ſheet of coarſe cotton, about ſix feet ſquare: on two oppoſite ſides are loops of the ſame ſtuff, through which a ſtring is run, and thereof other loops are formed, all which are tied together with a cord; and thus is the whole faſtened to two neighbouring trees in the field, or two hooks in houſes.

This kind of couch ſerves, at the ſame time, for bed, quilts, ſheets, pillow, &c.

The hammoc uſed on board of ſhips is made of a piece of canvas ſix feet long and three feet wide, gathered or drawn together at the two ends; there are uſually from fourteen to twenty inches in breadth allowed between decks for every hammoc in a ſhip of war; but this ſpace muſt in ſome meaſure depend on the number of the crew, &c. In time of battle the hammocs and bedding are firmly corded and fixed in the nettings on the quarter-deck, or wherever the men are too much expoſed to the view or fire of the enemy.

M. Le Cat has contrived a hammoc of Turkey leather, which may be eaſily raiſed or let down with a ſick perſon in it, by ropes and pullies. See Phil. Tranſ. N 468. § 3

HAMMON, in the *Heathen Mythology*. See AMMON.

HAMMON, or CHUMON, in *Ancient Geography*, a city of Aſher, (Joſh. xix. 28.) the ſame with the city of this name, ſaid to belong to Naphtali, 1 Chron. vi. 76.

HAMMOND, HENRY, in *Biography*, was born at Chertſey, in Surrey, in the year 1605. He was educated at Eton ſchool, where he made a rapid progreſs in the learned languages, and was transferred, when he was only thirteen years of age, to Magdalen college, Oxford. Here in due courſe he took his degrees, and was made fellow in his college, where he had been appointed to the office of reader of the lectures in natural philoſophy. During his reſidence at the univerſity, he generally ſpent thirteen hours a day in his ſtudies, among which was a particular regard to theology, and the holy ſcriptures: to theſe he applied himſelf to diſcover their ſenſe, without following the judgment of others. In 1633 he was, from the remarkable fine ſtyle of his preaching, preſented with the rectory of Penſhurſt in Kent, the duties of which he performed with exemplary diligence. In 1642 he was made archdeacon of Chicheſter, and nominated one of the aſſembly of divines at Weſtminſter, but never took his ſeat among them. He took a decided part in favour of the king's party, but was permitted to live in peace till the year 1643, when a reward being offered for his apprehenſion, he thought it right to abſcond, and eſcape to Oxford, where he lived wholly retired, taking no other amuſement than what the giving encouragement and inſtruction to ingenious young men afforded him, and the ſatisfaction which he received from the converſation of the learned. In 1644 he publiſhed his "Practical Catechiſm," which, though oppoſed by the Calviniſts, paſſed through many editions during the author's life. After this Dr. Hammond was preſented by the king to a canonry of Chriſt church, and elected public orator to the univerſity of Oxford; he was alſo appointed one of his majeſty's chaplains in ordinary. Without following the doctor in the minutiæ of his hiſtory, we may obſerve that he attended the king during his ſeveral impriſonments till Chriſtmas 1647, when the monarch was deprived of his ſlender houſhold. Dr. Hammond, being now without employment, returned to Oxford, where he was choſen ſub-dean of Chriſt-church, in which office he continued managing the affairs of the college with much diligence and ability, till the month of March 1648, when he was ejected by the parliamentary viſitors. He was not permitted to leave the place, but was, with Dr. Sheldon, kept priſoner in that city for ſeveral weeks. In this confinement his mind was alive to the purſuits of literature, and he began to prepare for the preſs his learned and valuable "Paraphraſe on the New Teſtament." Previouſly to the trial of his ſovereign, he was reſolved to make one effort in his favour, by writing to the perſons in power in behalf of the king. What he wrote was afterwards publiſhed under the title of "To the Right Honourable the Lord Fairfax and his council of War, the Humble Addreſs of Henry Hammond." The application produced no effect, and the execution of Charles ſoon followed, which excited in him the moſt poignant grief. In 1649 he removed into Worceſterſhire, to the ſeat of ſir John Packington, under whoſe hoſpitable roof he ſpent the remainder of his days. In 1653, he publiſhed his "Paraphraſe and Annotations on the New Teſtament," in folio. He had been led to this great undertaking from the careful and attentive ſtudy of the New Teſtament, with reference to the cuſtoms of the Jews and of the firſt heretics in the Chriſtian church, and alſo of the heathens, eſpecially in the Grecian games, and above all, the importance of the Helleniſtical dialect, into which he had made the exacteſt ſearch; and having, ſome years before, collated ſeveral copies of the New Teſtament, obſerved the variation of our Engliſh from the original, and made an entire tranſlation of the whole for his private uſe: he caſt his work into the form in which it appears. Dr. Hammond did not confine himſelf to the elucidation of the ſcriptures of the New Teſtament, but furniſhed a commentary on the whole Old Teſtament, which was publiſhed in 1659. He died of the ſtone, in the year 1660, in the fifty-fifth year of his age. Had he lived a ſhort time longer, there is reaſon to believe he would have been nominated to the biſhopric of Worceſter by Charles II., as well on account of his great learning and zeal in his profeſſion, as for his attachment to the cauſe of the late king. Dr. Hammond was author of many other works beſides thoſe already mentioned. His natural abilities were very conſiderable, and his learning deep and extenſive, the reſult of indefatigable ſtudy and application. As a preacher he was truly eloquent; Charles I. uſed to ſay

of him that he was the moſt natural orator he ever heard. In private life, he was of a ſocial, benevolent, and friendly diſpoſition, and particularly kind and liberal to the poor and diſtreſſed. Biſhop Burnet ſays his death was an unſpeakable loſs to the church: for as he was a man of great learning, and of the moſt eminent merit; ſo he was a very moderate man in his temper, though with a high principle, and would probably have fallen into healing counſels. Biog. Brit.

Hammond, James, a popular elegiac poet, born in 1710, was educated at Weſtminſter ſchool, and early in life obtained the friendſhip of ſeveral perſons of diſtinction, among whom were the lords Cheſterfield and Lyttleton. He was appointed to the place of equerry to Frederic prince of Wales, and ſerved as member of parliament for Truro in Cornwall. An unfortunate paſſion for a young lady, who was cold to his addreſſes, is ſaid to have diſordered his mind, and probably to have contributed to his death, which took place when he was only thirty years of age. His "Love Elegies," by which he is known as an author, were publiſhed after his death by the earl of Cheſterfield. They have gone through many editions, but it detracts from their merit that they conſiſt, almoſt entirely, of tranſlations or imitations of paſſages in Tibullus. Two of the elegies to his friend Mr. Grenville, and to his miſtreſs, prove that he was able to write pathetically on real topics, and much praiſe is due to him for the ſweetneſs and elegance with which ſome of the fineſt ſentiments of Tibullus are rendered. Lives of the Poets by Johnſon.

Hammond, *Cape*, in *Geography*, the S. extremity of Kaves iſland, in the N. Pacific ocean. N. lat. 59° 48'. E. long. 215°.

Hammond's *Iſland*, a ſmall iſland near the S. coaſt of New Georgia, ſo named by lieutenant Shortland in 1788. S. lat. 8° 46'. E. long. 157° 5'.

HAMMOSTEUS, the oſteocolla of the ſhops.

HAMNSHAR, in *Geography*, a ſmall iſland on the E. ſide of the gulf of Bothnia. N. lat. 63° 54'. E. long. 23° 39'.—Alſo, a ſmall iſland on the W. ſide of the gulf of Bothnia. N. lat. 63° 25'. E. long. 20°.

HAMOA, an iſland of the Pacific ocean, in the vicinity of the Friendly iſlands, or forming part of the group. It is repreſented as larger than Tongataboo, though under its dominion, and about two days ſail N.W. from Vavaoo. This, indeed, is deſcribed as the largeſt of all the iſlands in that part of the ocean, as affording harbour and good water; and as producing, in abundance, every article of refreſhment found at other places that were actually viſited. The people of this iſland ſeem to be in high eſtimation at Tongataboo, for our navigators were told, that ſome of the ſongs and dances with which they were entertained, had been copied from thoſe people, and they ſaw ſome houſes ſaid to be built after their faſhion. Cook's Third Voyage, vol. i. p. 372.

HAMOAZE, a creek or bay in the Engliſh channel, the weſtern branch or main ſtream of the river Tamar, which falls into Plymouth ſound, and forms a harbour for the Britiſh navy, capable of containing 100 veſſels; which uſually lie at anchor in three tiers, in thirteen or fifteen fathoms water.

HAMOTE, a long iſland at the entrance of Queen Charlotte's ſound, in New Zealand, betweeen which and Motuara, another iſland, there is a paſſage into the harbour, called by Cook "Ship Cove."

HAMPDEN, John, in *Biography*, celebrated in the political hiſtory of this country, was born at London in 1594, and was at an early age entered as a gentleman commoner at Magdalen college, Oxford. After remaining there three years, he applied himſelf diligently to the ſtudy of the law, and had made much progreſs in the ſcience, when the death of his father put him in poſſeſſion of a large eſtate, and rendered it unneceſſary for him to continue the purſuit. For ſome time he indulged himſelf in the unreſtrained courſe of life uſual among country gentlemen, till the ſerious aſpect of the times brought him to reflection. He was a relation to Oliver Cromwell, and attached himſelf to the party in oppoſition to the court. About the year 1626, he was brought into parliament, but though an uniform oppoſer of arbitrary meaſures, he took no very decided part in the houſe. In 1637, he was one of thoſe who had engaged a ſhip to tranſport themſelves to America, rather than ſubmit to the tyrannical proceedings of the ſtar-chamber. Fortunately for the country, they were prevented from ſailing; and in a ſhort time, the ſubject of this article began to diſtinguiſh himſelf by a noble reſiſtance to the illegal demand of ſhip-money. It was after the declaration of the judges in favour of the king's right to levy ſhip-money, that Hampden refuſed the payment. A proſecution was inſtituted againſt him: for twelve days the caſe was argued before the judges, eight of whom decided againſt him, but the right, the law, and the people were with him, and from thenceforth he received, as he merited it, the noble appellation of the "patriot Hampden." From this moment he was a leading man in the conteſt between an arbitrary king and the people; he who, but a ſhort time before, was ſcarcely known, became now the object of every man's ſolicitude. Perſons of all claſſes began to enquire who and what he was, that durſt, at his own expence and peril, ſupport the liberty and property of the kingdom, and reſcue his country from being made a prey to the court. His power and intereſt were greater than thoſe which any other man poſſeſſed. He was a member of the Long parliament, and various important duties were aſſigned him in and out of the houſe. When a ſcheme was agitated for admitting ſome of the popular party into adminiſtration, the poſt of preceptor to the young prince was deſigned for Hampden, which ſhews how highly his character was eſtimated for talents and purity. The project failed, the breach was widened; and now the illuſtrious Hampden was ſelected as one of five members, whom Charles I, in 1640, imprudently cauſed to be accuſed of high-treaſon, and attempted in perſon to ſeize in the houſe. When matters were carried ſo far that an appeal muſt be made to the ſword, Hampden accepted the command of a regiment of foot in the parliamentary army, under the earl of Eſſex: his military career was very ſhort, but long enough to enable him to make a glorious diſplay of the ſame courage in the field, which he had ſhewn in civil debate. He received a ſhot in an early engagement, which, in a few days, put an end to his valuable life. This event took place on the 24th of June, 1643, and ſo highly did the king reſpect him, that it is ſaid, he ſent his own phyſicians and ſurgeons to viſit him, and to render him all the aid of their profeſſional talents. His death was probably the ſubject of rejoicing to the royal party, but of the deepeſt grief and affliction to his own. He could not be deſtitute of ambition, but it was of that kind which enabled him to benefit his country: it never rendered him incapable of ſwerving from the line of ſtrict integrity. Biog. Brit. Hume's Hiſt.

Hampden, in *Geography*, a poſt-town of America, in Hancock county, and ſtate of Maine; 734 miles N.E. of Waſhington.

HAMPSHIRE, or, as called in legal proceedings, the county of Southampton, and county of Hants, a diſtrict of England,

HAMPSHIRE.

England, bordering on the Engliſh Channel, and having Dorſetſhire, and part of Wiltſhire on its weſtern limits, while the latter county, and part of Berkſhire, ſkirt it on the ſouth, and Surry attaches to the eaſtern border. The area of land, thus ſurrounded, is calculated to extend about 42 miles in length, by 38 in breadth; and to contain 1,112,000 acres, of which 600,000 are ſuppoſed to be appropriated to paſturage, 300,000 to arable, and the remainder in foreſt, common, and waſte. In this arrangement, the Iſle of Wight, a part of Hampſhire, is not included. For civil purpoſes the whole is divided into 39 hundreds and liberties, which are again ſubdivided into 293 pariſhes: it has one city, (Wincheſter,) twenty market towns, and about 1000 villages and hamlets. According to the population report of 1801, it contained, (including the Iſle of Wight,) 39,257 houſes, and 219,656 inhabitants: of the latter 105,667 are males, and 111,989 are females. Hampſhire, with the Iſles of Wight, Jerſey, Guernſey, Sark, and Alderney, are in the dioceſe of Wincheſter. The county returns twenty members to the Britiſh parliament: *viz.* two for the ſhire, two for Wincheſter, and two for each of the following boroughs: Southampton, Portſmouth, Petersfield, Stockbridge, Chriſtchurch, Lymington, Whitchurch, and Andover: ſix members are alſo returned for the boroughs of Newport, Yarmouth, and Newton, in the Iſle of Wight. A particular account of this iſland will be given in the letter I.

Ancient Hiſtory.—The aboriginal inhabitants of this diſtrict are ſaid to have migrated from the continent at a very remote period; and to have acquired the name of Segontiaci. Theſe were diſpoſſeſſed by the Belgæ, a German tribe, who are deſcribed by hiſtorians as having come into this iſland between two and three centuries before the arrival of Julius Cæſar. The Belgæ, (ſee vol. iv. of this work), appear to have been a powerful people, and to have obtained poſſeſſion of a large tract of country before the Roman conqueſt. Subdued, however, by theſe military invaders, their country was named Britannia Prima, afterwards Flavia Cæſarienſis, and was occupied by the following military towns or ſtations: Venta-Belgarum, Wincheſter; Clauſentum, Bitter, near Southampton; Portus Magnus, Porcheſter; and Vindonum, Silcheſter; other encampments, and traces of Roman roads, are to be ſeen in different parts of the county. Under the Anglo-Saxon dynaſty, this diſtrict was part of Weſſex, and Wincheſter became the capital. The name of the county was now changed into Hantunſcyre, and in Wincheſter Egbert was crowned king of all England.

Topography and Deſcription.—The ſurface of Hampſhire preſents a continued variation of gently riſing hills and fruitful vallies, adorned with numerous ſeats and villages, and interſperſed with extenſive woodlands. Its ſouthern parts were the firſt inhabited, and there the population is ſtill the greateſt; the mildneſs of the ſeaſons, and the convenience of the ports, operating as ſtrong inducements to continued reſidence. The chief part of the county is encloſed; though large tracts of open heath, and uncultivated land, remain in the vicinity of Chriſtchurch, and on the borders of Dorſetſhire. The aggregate extent of the waſte lands, excluſive of the foreſts, is ſuppoſed to include nearly 100,000 acres. The ſoils are extremely numerous, but the far greateſt proportion is tending to chalk; and a ridge of chalk-hills, or downs, may be traced acroſs the country in the parallel of Wincheſter. On the north ſide, bordering on Berkſhire, the ſoil is deep, and very productive: here great quantities of corn are annually grown, and the elm and the oak flouriſh greatly; though the latter, in many inſtances, has been originally tranſplanted. On the acclivities of the hills towards Baſingſtoke, the land is in general very deep and ſtrong, with chalk beneath: round Whitchurch it is ſhallower, and leſs chalky, but produces good crops of corn and ſainfoin. A beautiful vale divided into well-watered meadows, and producing from two to three loads of hay per acre, extends from Overton towards Stockbridge, and thence to Redbridge. The land round Andover is high and down-like; yet the ſoil, though thin, is very favourable to the growth of barley: towards Romſey it is yet more fertile; and the land is well cultivated, and interſperſed with woods, and fine hedge-row timber. South and ſouth-weſt of Romſey, the country is principally occupied by the New Foreſt; though very large open tracts ſtill remain, as already ſtated, on the borders of Dorſetſhire, and in the vicinity of Chriſtchurch: the ſoil of the New Foreſt is chiefly loam and gravel. Valuable ſalt-marſhes are found about Redbridge. The pariſhes eaſtward of Alton, and bordering on Surrey, are chiefly appropriated to the growth of hops, the plantations of which have been conſiderably augmented, through the reputation of the Farnham hops; yet, though equally good, and the produce of contiguous grounds, ſuch is the faſcination of a name, that the price they bear at market is generally from forty to fifty ſhillings per hundred weight below thoſe with the Farnham mark. About 800 acres are ſuppoſed to be occupied by the hop-grounds: the produce, though varying conſiderably, may be averaged at about five cwt. per acre. The land towards Petersfield is more open, with great quantity of down; approaching Portſmouth, it is more incloſed, and interſperſed with timber and underwood. The hills round Fareham and Warnford are chalky, and partly covered with beech wood: here are alſo extenſive downs; and the banks of the river Itchin are enriched with ſome valuable water meadows.

Hampſhire has obtained high reputation as a breeding country, and particularly for ſheep and hogs. The original Hampſhire ſheep is horned and white-faced: the flocks are generally large, and the downs are moſtly covered with them: the whole number of ſheep annually fed in the county is eſtimated at 350,000. For its breed of hogs, Hampſhire is proverbially famous; and this breed is of the largeſt kind, ſuch being encouraged by the farmers as moſt productive. Thoſe in the vicinity of the foreſts are principally fed on acorns and beech-maſt, which give them a ſuperiority over moſt others in the kingdom: their weight is from ſixteen to forty ſcore each.

A very conſiderable proportion of Hampſhire is occupied by the foreſt of Alice Holt and Woolmer, the foreſt of Bere, and the New Foreſt. The former is ſeparated into two portions by intervening private property: its area comprehends about 15,498 acres, of which 8694 belong to the crown. On a ſurvey made of the timber of this foreſt in the year 1608, 1301 oak trees were returned as fit for the uſe of the navy; and 23,934 loads as defective: this quantity has ſince greatly decreaſed; and in 1783, the ſound and defective wood together amounted to only 15,142 loads; and thoſe were of trees moſtly of one age, that is, from 100 to 120 years, without any having been planted to ſucceed them. This foreſt is ſituated on the borders of Surrey and Suſſex. The foreſt of Bere extends northward from the Portſdown hills, and, according to the perambulation made in the year 1688, and now conſidered as the boundary, it includes about 16,000 acres, of which one-third is encloſed. This foreſt is divided into two walks, reſpectively named Eaſt and Weſt. From a ſurvey of the timber in this foreſt made in the year 1783, it appears that the quantity then growing was only a twenty-eighth part of what was ſtanding in the year 1608; and by the many incroachments made in modern times, its boundaries were continually decreaſing.

The New Foreſt is particularly celebrated in hiſtory, from the vaſt enlargement of it by William the Conqueror, and from its being the ſcene of the accidental death of his ſucceſſor William Rufus. Its preſent appellation has an evident reference to the alteration made in its extent by the Conqueror: but a more ancient name of this diſtrict was Itene, or Y. Thene: it was alſo called Natanleod, from the Britiſh chieftain, who was here conquered by Cerdic, the founder of the Weſt-Saxon monarchy.

For further particulars reſpecting the important tract, ſee NEW FOREST.

The principal rivers in Hampſhire are the Itchin, the Avon, the Boldre Water, the Exe, the Anton, and the Teſe or Teſt; ſeveral ſmaller ſtreams riſe in the north-weſt parts, but ſoon leave the county. The Itchin has its ſource near the middle of the county, and being ſoon increaſed by the Alne, flows weſtward to King's Worthy; where, turning to the ſouth, it paſſes Wincheſter, Twyford, and Biſhopſtoke, and falls into the Southampton water, about half a mile eaſtward from the town. The Avon enters the county from Wiltſhire, and meanders in ſeveral channels near the New Foreſt; whence, paſſing Fordingbridge and Ringwood, it flows towards Chriſtchurch, and having received the waters of the Stour, unites with the ſea in Chriſtchurch bay. The Boldre Water is formed by various ſprings that riſe in the New Foreſt, and unite above Brokenhurſt; whence, in a ſingle ſtream, they paſs Boldre and Lymington to the ſea. The Exe has alſo its ſource in the ſame diſtrict, and opens in a broad eſtuary to the ſea below Exbury. The Anton riſes in the north-weſt angle of the county, and, flowing through part of Andover, runs into the Teſe, below Whirwell. The Teſe has its origin near Whitchurch, and, after its junction with the Anton, paſſes Stockbridge and Romſey, and, opening below Redbridge, it forms the head of the Southampton Water, which is properly an arm of the ſea, extending from above Southampton to Calſhot caſtle. Driver's Agricultural Survey of Hampſhire. Warner's Topographical Remarks on Hampſhire, &c. 2 vols. 8vo. Vancouver's Agricultural Survey of Hants, 8vo. 1810.

HAMPSHIRE, an extenſive, populous, and wealthy county of America, in Maſſachuſetts, which was made a ſhire in 1662. It is in many parts mountainous and hilly, and extends acroſs the ſtate from N. to S.; bounded N. by the ſtates of New Hampſhire and Vermont, S. by the ſtate of Connecticut, E. by Worceſter county, and W. by Berkſhire. It contains 62 townſhips and 72,432 inhabitants. Its principal towns lie on both ſides of Connecticut river, which interſects it from N. to S. Theſe are Springfield, Weſt Springfield, Northampton, Hudley, Hatfield, Durfield, and Northfield. This is one of the moſt fertile, as well as populous, counties in the ſtate. A copper mine has been diſcovered in Leveret, and black lead in ſeveral other places.—Alſo, a county in Virginia, bounded N. and N.W. by the Potowmack river, which divides it from the ſtate of Maryland, about 60 miles long and 50 broad; containing 7310 free inhabitants, and 587 ſlaves. Iron ore and coals have been diſcovered on the banks of the Potowmack. Its chief town is Romney.

HAMSOKEN, the liberty or privilege of a man's own houſe; alſo a franchiſe granted to lords of manors, whereby they hold pleas, and take cognizance of the breach and violation of that immunity: and it likewiſe ſignifies "quietantiam miſericordiæ intrationis in alienum domum vi & injuſte." Fleta, cap. 47. In Scotland, violations of this kind are equally puniſhable with raviſhing a woman, And our old records expreſs burglary under the word *hamſocne*.

HAMPSTEAD, or HAMESTEDE, as the name was formerly written, in *Geography*, a pariſh in the hundred of Oſſulton, and county of Middleſex, England, is juſtly regarded as the moſt pleaſant ſituation for villas in the vicinity of London. Hence it abounds with reſpectable houſes belonging to the higher claſſes of merchants and tradeſmen, who have other dwellings, counting-houſes, &c. in the metropolis. The buildings of Hampſtead are irregularly diſperſed over the ſummit, and the ſouthern and weſtern ſides of a hill, which riſes to a conſiderable elevation, and is very ſteep in many places. At the top of the hill is a piece of waſte land, called Hampſtead-common, from various ſtations on which extenſive, diverſified, and intereſting views are obtained, of a fertile, pictureſque tract of country to the north and north-weſt, and of an expanſive flat to the ſouth, ſouth-eaſt and ſouth-weſt, terminated by the Surrey hills and Epping foreſt. In the midſt of this flat are the immenſe connected cities of London and Weſtminſter, with the borough of Southwark, and numerous villages and hamlets, all really, or apparently connected with the Britiſh metropolis. To a foreigner, and even to a native of London, this ſcene muſt prove ſingularly intereſting and attractive; and each will contemplate with ſome aſtoniſhment, the vaſt congregation of houſes, churches, and public buildings, that are indiſtinctly ſpread before him. Nor is the fore-ground devoid of intereſt and pictureſque features: for the red ſandy ſoil, broken clumps of ground, furze, heath, and old trees, all conſpire to render the home ſcene "highly pleaſing and beautiful." The whole hill is alſo adorned with many plantations of old and young trees; among which there are numerous elms of large ſize. The inequality of ground, and abruptneſs of ſome declivities, may be alſo enumerated among the natural beauties of the place. From theſe attractions, and its nearneſs to the central part of London, being leſs than five miles from Somerſet-houſe, Hampſtead is nearly covered with buildings, and the value of land has been greatly advanced within the laſt century. This pariſh comprehends 2169 acres, of which about 200 may be conſidered waſte. Though Hampſtead has few attractions to the antiquary, yet it ſeems that a Roman villa, or ſome Roman reſidence, was eſtabliſhed here during the Anglo-Roman dynaſty; for, in the year 1774, ſeveral ſepulchral urns, vaſes, earthen lamps, &c. were dug up in a place called the Wells Walk. (See Gent. Mag. for 1776. p. 169.) The manor was given in 986, by king Ethelred, to the church of Weſtminſter. In the Doomſday-book it is deſcribed to contain four hides. Since the diſſolution of monaſteries, it has been poſſeſſed by ſeveral different families. Near the S.W. end of the village is the church, which was newly built, and conſecrated in Oct. 8, 1747. Before the year 1477, this place was only a chapelry to Hendon, but it was then made a donative, or perpetual curacy. In the year 986 Hampſtead contained only five cottages. Mr. Lyſons ſtates that the population increaſed during the 17th and 18th centuries, at the rate of ſeven to one. In 1801 the pariſh contained 738 houſes and 4343 inhabitants. Near the eaſtern extremity of the village is a ſpring of mineral water, which was formerly much frequented. Mr. Goodwin, a medical practitioner here, has publiſhed a ſmall volume (1804) deſcriptive of the properties of the mineral waters of Hampſtead. For many other particulars relating to Hampſtead, ſee Lyſons's Environs of London, v. ii.

HAMPSTEAD, a town of America, in Rockingham county, New Hampſhire, about 34 miles W. of Portſmouth; incorporated in 1729, and in 1800 containing 790 inhabitants.

HAMPTON, a pariſh in the hundred of Spelthorne, and county of Middleſex, in England, is ſeated on the northern bank of the river Thames, at the diſtance of 12 miles S.W.

of

of London. This place is diſtinguiſhed by a magnificent palace, called Hampton-court, which, though not originally built, was greatly enlarged by cardinal Wolſey, who gave it to the king in the year 1526. After this period, the monarch again extended the buildings, and added much to their embelliſhment. The preſent edifice conſiſts of various dwellings and offices, with a chapel and a hall; all of which ſurround three quadrangular courts, and occupy an area of ground meaſuring about 700 feet from eaſt to weſt, by 400 feet from north to ſouth. Many alterations and additions were made to the palace by king William, from deſigns by ſir Chriſtopher Wren. The royal family have not reſided at, or occupied this palace for many years. Its numerous apartments are now occupied by various perſons, who are chiefly preſented with theſe reſidences by the lord chamberlain, and by other miniſters of the crown. The prince of Orange, with his family and ſuite, have a ſuit of apartments here. Several of the public rooms are decorated with paintings, ſome of which are the works of eminent maſters. Among theſe are the ſeven celebrated cartoons by Raphael. They repreſent ſo many paſſages from ſcripture hiſtory, and are eſteemed among the moſt admirable productions of that diſtinguiſhed maſter. A ſeries of highly finiſhed plates from theſe are now in the progreſs of engraving by Mr. Holloway. To particularize the numerous other works of arts, and briefly notice the chapel, the noble hall, the gardens, graperies, &c. would render this article longer than conſiſtent with the nature of the publication. The reader is, therefore, referred, for ſuch information, to Lyſons's Environs of London, vol. v. and the lateſt guide to Hampton-court. This palace was occupied by king Henry VIII. during the latter part of his reign; when it was rendered a ſcene of great pomp and ſplendour, and it is ſaid that 280 ſilk beds were reſerved for viſitors. Edward VI. was born here, and queen Jane Seymour died at this place in the ſame month, *viz.* Oct. 1537. In 1540 the monarch introduced Catharine Howard to this palace, where, in 1543, the ſame ſanguinary tyrant was married to Catharine Parr. Philip and Mary kept the Chriſtmas of 1558 at Hampton-court, at which feſtival the palace was illuminated with 1000 lamps; various feats, ſports, and revels were held; and in a juſting match on the 29th of Dec. 200 ſpears were broken. Queen Elizabeth reſided here occaſionally, and king James I. aſſembled the Preſbyterians and members of the eſtabliſhed church here 1603-4, to hold a conference reſpecting a new tranſlation of the bible, and alterations in the liturgy. King Charles I. held ſeveral interviews with ambaſſadors here, and in 1647 was impriſoned within theſe walls. After his decapitation, Cromwell made it his principal reſidence; and ſubſequently it was progreſſively occupied by kings Charles II. James II., William, George I., and George II. In 1540 an act of parliament was paſſed for creating the manor of Hampton-court an honor; which comprehends 16 manors, beſides a tract of land called the Chaſe. The latter was made in 1538, for the purpoſe of preſerving game immediately contiguous to the palace, whereby his majeſty might enjoy the ſports of the chaſe, without the fatigue of travelling far from home. In this pariſh is Buſhy-park, the reſidence of the duke of Clarence: and Hampton-houſe, the elegant villa of the late Mr. Garrick. The church contains ſeveral monuments. In 1548 here were 230 houſlying people in this pariſh; and in 1801 the houſes are ſpecified at 141, and the population at 1722.

Hampton, a townſhip of America, in Windham county, Connecticut, 8 miles N.E. of Windham; containing 1379 inhabitants.

Hampton, *Eaſt*, a townſhip in Hampſhire county, Maſſachuſetts, S. of Northampton; incorporated in 1785, and containing 586 inhabitants.—Alſo, a half-ſhire town of Suffolk county, on the E. end of Long iſland, New York; containing 1549 inhabitants, and an academy, which in 1791 had 92 ſtudents.

Hampton, the *Winicowett* of the Indians, a townſhip on the ſea-coaſt of New Hampſhire, on the eaſtern ſide of Rockingham county, incorporated in 1638, and in 1800 containing 875 inhabitants; 8 miles S.E. of Exeter. In 1791 a canal was cut through the marſhes in this town, which opens an inland navigation for loaded boats, from Hampton through Saliſbury, into Merrimack river, for about eight miles.

Hampton *Falls*, a ſmall town taken from that laſt mentioned, lying on the road which paſſes from Exeter to Newbury port, ſix miles S.E. of the former and eight N. of the latter; incorporated in 1712, and in 1800 containing 519 inhabitants.

Hampton, a townſhip in the northern part of Waſhington county, New York, containing 700 inhabitants.—Alſo, the capital of Elizabeth county, in Virginia; a port of entry and poſt-town, ſituated at the head of a bay, running up N. from the mouth of James river, called "Hampton road," 5 miles N.W. of Point Comfort. It contains about 30 houſes, an epiſcopal church, a court-houſe and gaol. It was anciently called "Kecoughton" by the Indians; 18 miles N. of Norfolk. It exports grain, lumber, ſtaves, &c.

HAMRA, a ſmall iſland in the Red ſea; near the coaſt of Arabia. N. lat. 25° 30'.

HAMRACHI, a town of Perſia, in Segeſtan; 180 miles S.E. of Zareng.

HAMRAH, *Ras-el-Hamra, Cape*, on the coaſt of Algiers, anciently called "Promontorium Hippi." N. lat. 37°. E. long. 7° 58'.

HAMRANGE, a town of Sweden, in Geſtricia, ſituated in a bay of the gulf of Bothnia; 14 miles N. of Gefle. N. lat. 60° 55'. E. long. 16 52'.

HAMSTEAD, a town of America, in Rockland county, New York, W. of Hudſon river; containing 1981 inhabitants.

Hamstead, or *Hemſtead, North* and *South*, are ſituated in Queen's county, Long iſland, New York; 23 miles E. of New York city.

HAMSTED Point, a cape on the N. coaſt of the Iſle of Wight. N. lat. 50° 43'. W. long. 1° 16'.

HAMSTER, Siberian, in *Zoology*. See Mus *Acredula*.

Hamster, *German*. See Mus *Cricetus*.

HAMULARIA, a new genus of inteſtinal worms eſtabliſhed by Treutler, in a diſſertation lately printed at Leipſic. The body is linear and cylindric, the head obtuſe, and beneath an armament of two crochets. Only a ſingle ſpecies of this genus has been hitherto diſcovered, and that is ſpecifically named *lymphatica*. It was found upon the external part of the tracheal artery of a man who died of a conſumption, where it appeared in cluſters interwoven with each other. This animal, the length of which is about an inch, very much reſembles ſome kinds of the aſcarides, but as the latter reſide in the inteſtines, the habits of the hamulariæ ſeem to indicate a peculiar difference, and probably an organization materially diſtinct.

HAMUS, or Hamulus, a hook.

Surgeons alſo make uſe of an inſtrument thus called, to extract the child in difficult labours.

HAMWARDS, in *Rural Economy*, a term provincially applied, in ſome places, to ſtraw or ruſh-collars for horſes or other animals.

HAMZAH, in *Biography*, the principal founder of the Druſes in Syria, commenced his public career at Cairo, under the reign of Hakem-Bamrillah, about the commencemens of the eleventh century of the Chriſtian era. He became a diſciple of Mahomet Ebn Iſhmael, ſurnamed Durzi, who is ſuppoſed to have inſpired *Hakem* (ſee his article) with the impious conceit of his being God incarnate. After the maſſacre of the new prophet, Hamzah was encouraged to aſſume his office, and to propagate the doctrine of Hakem's divinity through his dominions. He gained a multitude of ſupporters and followers among the Druſes in the mountains of Syria, whoſe deſcendants ſtill maintain his peculiar tenets, and particularly the fundamental one, that the great creator of the univerſe became incarnate in Hakem, in order to inculcate on mankind the principles of true religion, and to exhibit in his perſon an object of adoration ſuited to their limited and imperfect conceptions. Hamzah aſſumed the character of high prieſt and prophet of the religion of the Druſes, which was a compound of Mahometaniſm and Catholic Chriſtianity. The followers of this ſyſtem, if ſo it can be denominated, are ſo ignorant, that nothing preciſe concerning their belief can be learned from them or their prieſts. The work, which is held in the higheſt eſtimation among them, was compoſed by Hamzah, and is entitled "The Book of Teſtimonies to the Myſteries of the Unity." It was intended as a rival to, or ſubſtitute for the Koran, and is thought by ſome to be ſuperior to it in point of purity and elegance of ſtyle. A copy of the work was, towards the concluſion of the 17th century, lodged in the royal library at Paris, where it was tranſlated from the Arabic into the French language. Moreri.

HAN, in *Geography*, a city of China, of the ſecond rank, in the province of Se-tchuen. N. lat. 31°.

HAN, a ſmall iſland near the coaſt of Scotland. N. lat. 58° 37'. W. long. 4° 35'.

HANAMINE, a ſmall iſland near the weſtern coaſt of Ireland, and county of Galway; 2 miles N.W. of Rinuell point.

HANAB ALTHALEB, in the *Materia Medica*, a name uſed, by the ancient Arabian writers, to expreſs the *lycoperſicum*, or *pomum amoris*.

HANAPER, or HAMPER, an office in chancery, under the direction of a maſter, his deputy and clerks, anſwering, in ſome meaſure, to the fiſcus among the Romans.

HANAPER, *Clerk of the*. See CLERK *of the Hamper*, &c.

HANAU, in *Geography*, a town of Germany, capital of Hanau Munzenburg, on the Kinzig, where it joins the Maine. It is divided into Old and New Town; the former received its charter in 1303, and the latter was built in 1597 by the Walloons, who fled from the perſecutions of Philip II. king of Spain. This town contains ſeveral churches, with manufactures of woollen, ſilk, cotton, porcelain, &c. and alſo roll-tobacco: but the chief articles of its trade are timber, caſt-iron, meal and corn; 8 miles E. of Francfort on the Maine. N. lat. 50° 9'. E. long. 8° 59'.

HANAU *Munzenburg*, a county and principality of Germany, ſituated for the moſt part on the Maine, between the electorate of Mentz, bithopric of Fulda, and principality of Heſſe Homburg; about 45 miles long, and 15 wide. It is deemed one of the moſt fertile and rich countries in Germany, producing grain, legumes, exquiſite wine, and delicious fruits. It contains magnificent foreſts, mines of ſalt, copper, ſilver, and cobalt. It was erected into a county in 1439, and fell by compact to the landgrave of Heſſe Caſſel in 1736.

HANBAL, AHMED EBN, in *Biography*, one of the chiefs of the four ſects recognized as orthodox among the Mahometans, was born at Bagdat about the year 164 of the Hegira. He was eſteemed as a doctor profoundly ſkilled in the law, the traditions, and the devotional obſervances obligatory on the diſciples of the prophet. He viſited all the principal cities in the Eaſt, where he propagated his opinions, and acquired univerſal reſpect by his virtues. But notwithſtanding his high character, he was impriſoned, and ordered to be cruelly ſcourged, for refuſing to ſubſcribe to the opinion that the Alcoran was created. The contrary opinions, maintained by the orthodox, expoſed them, at this period, to cruel perſecutions from the princes of the houſe of Abbas. Hanbal was kept in priſon till the ſucceſſion of a new prince, when he was ſet at liberty, and richly compenſated for all his ſufferings. Hanbal, on account of his perſecutions, eſtabliſhed a ſect, named after himſelf Hanbalites, who attracted much notice about a century after the death of the founder. At this period, the head of the ſect maintained that God would hereafter place Mahomet upon the throne of his glory near himſelf. The other Mahometan ſects, while they condemned this doctrine as heretical and impious, maintain that the prophet would be exalted to the high honour of mediator and interceſſor for all true believers at the day of judgment. Theſe diſcordant opinions led to the moſt ſavage perſecutions, which were continued a long time, ſo that Bagdat was a complete ſcene of blood and confuſion. Hanbal died in the year 241, or 855 of the Chriſtian era. Univer. Hiſt.

HANCES, in a *Ship*, are falls or deſcents of the ſife-rails, which are placed as baniſters in the poop, &c. and down to the gang-way.

HANCES, or *Hanſes*, in *Architecture*, are the ends of elliptical arches, which are arcs of ſmaller circles than the ſcheme or middle part of the arch.

HANCOCK, in *Geography*, a large maritime county of America, in the ſtate of Maine, bounded N. by Lower Canada, S. by the ocean, E. by Waſhington county, and W. by Lincoln and Kennebeck counties; 190 miles long from N. to S. and nearly 60 broad, interſected by Penobſcot river. It contains ſeveral townſhips and plantations; and the number of inhabitants is 16,336. It is well watered; and on the ſea-coaſt are many harbours and inlets, hidden by a multitude of fertile iſlands; the largeſt of which are ſituated in Penobſcot bay. The towns along the ſea-coaſt, and on the banks of the rivers Penobſcot and Union, are the moſt productive and populous. The ſhire-town is Caſtine.—Alſo, a county in the upper diſtrict of Georgia; containing 14,456 inhabitants, of whom 4835 are ſlaves.—Alſo, a ſmall poſt-town of Maryland, in Waſhington county, on the N. bank of Potowmack river; about 25 miles S.E. of Bedford in Pennſylvania.—Alſo, a long, narrow, and mountainous townſhip in the New York line, in Berkſhire county, Maſſachuſetts; incorporated in 1776, and containing 1187 inhabitants.—Alſo, a townſhip in Hilliſborough county, New Hampſhire, ſituated between two branches of Contoocook river; 14 miles E. of Keene; incorporated in 1779, and containing 1120 inhabitants.—Alſo, a town, now called *Clinton*, in Kennebeck county, Maine, enclоſed by the Kennebeck and Sebeſticook rivers.—Alſo, a townſhip in Addiſon county, Vermont, having 149 inhabitants.—Alſo, a river of Waſhington iſland, on the N.W. coaſt of North America, called "Maſbeet" by the Indians, diſcovered by Capt.

Capt. Crowell in 1791. It diſcharges itſelf into the ſea at the north end of the largeſt iſland, and at its mouth is nearly 2½ nautical miles wide. The land is low and apparently fertile; and the river abounds with ſalmon. The mouth of the river is in N. lat. 54° 7′. W. long. 131° 54′. Morſe.

Hancock's *Harbour*, called by the Indians "Clioquot," is ſituated about 20 leagues E.S.E. of Nootka, in N. lat. 48° 30′. W. long. 125° 26′. Its entrance is about five miles in length, and it has good anchorage. Several iſlands and ſeveral ſand-banks are diſperſed about it: it has alſo a number of fine coves. The land round the harbour is generally rocky and mountainous, covered, however, with pine, fir, ſpruce, cedar, hemlock, cypreſs, and other large trees. The climate is much milder than on the eaſtern ſide of the continent in the ſame latitude; the froſt, in winter, not preventing vegetation. An eaſterly wind is conſidered here as a prognoſtic of a ſtorm, and weſt winds bring fair weather. The foreſts abound with deer, raccoons, wolves, bears, ſquirrels, martins, land otters, beaver, and wild cats. The amphibious animals in this place are the common ſeal and ſea-otter. The inhabitants are ſaid to be cannibals. This and other places of the ſame name have their appellation in honour of the late governor Hancock of Maſſachuſetts.

HAND, Manus, a part or member of the body of man, making the extremity of the arm.

The mechaniſm of the hand is very curious; excellently contrived to fit it for the various uſes and occaſions we have for it, and the great number of arts and manufactures it is to be employed in. It conſiſts of a compages of nerves, and little bones joined into each other, which give it a great degree of ſtrength, and at the ſame time an unuſual flexibility, to enable it to handle adjacent bodies, lay hold of them, and graſp them, in order either to draw them toward us or thruſt them off. Anaxagoras is repreſented, by ancient authors, as maintaining, that man owes all his wiſdom, knowledge, and ſuperiority over other animals, to the uſe of his hands. Galen repreſents the matter otherwiſe: man, according to him, is not the wiſeſt creature, becauſe he has hands; but he had hands given him becauſe he was the wiſeſt creature; for it was not our hands that taught us arts, but our reaſon. The hands are the organs of reaſon, &c. De Uſu. Part. lib. i. cap. 3. For an anatomical deſcription of the hand, ſee Extremities.

The hand makes the ſubject of the art of palmiſtry, which is employed in conſidering the ſeveral lines and eminences of the palm of the hand, their ſignifications, &c. Among the Egyptians, the hand was uſed as a ſymbol of ſtrength; among the Romans, it was held a ſymbol of fidelity: and, accordingly, was conſecrated to that goddeſs by Numa, with great ſolemnity.

Hand, in *Falconry*, is uſed for the foot of the hawk. To have a clean, ſtrong, ſlender, glutinous hand, well clawed, are ſome of the good qualities of a hawk, or falcon.

Hand, *Branding*, or *Burning in the*, in *Law*. See Branding.

Hand, *Diſabling of*. See Mayhem.

Hand, *Holding up of*. See Arraign.

Hand, *Loſs of*, a puniſhment inflicted for particular crimes. See Contempt, Court *of the Lord Steward of the King's Houſehold*, Owling, &c.

Hand, in the *Manege*, is a term variouſly uſed. Sometimes it ſtands for the fore-feet of a horſe.

Hand is alſo uſed for a diviſion of the horſe into two parts, with reſpect to the rider's hand. The *fore-hand* includes the head, neck, and fore-quarters; the *hind-hand* is all the reſt of the horſe.

Spear-hand, or *ſword-hand*, is uſed for a horſeman's right hand.

Bridle-hand is the horſeman's left hand.

A regular cavalier holds his bridle-hand two or three inches above the pommel of the ſaddle.

A horſeman is ſaid to have *no hand*, when he only makes uſe of the bridle unſeaſonably; not knowing how to give the aids, or helps, of the hand with diſcretion.

To keep a horſe *upon the hand*, ſignifies to feel him in the ſtay upon the hand, and to be always prepared to avoid any ſurpriſe from him. When the horſe obeys and anſwers the effects of the hand, he is ſaid to *reſt well upon the hand*.

A horſeman ought to have a *light hand*, *i. e.* he ought only to feel the horſe upon his hand, ſo as to reſiſt him whenever he attempts to ſlip from it; and as ſoon as he has made his reſiſtance, he ought to lower the bridle, inſtead of cleaving to it.

If a horſe, by a too great eagerneſs to go forward, preſſes too much *upon the hand*, it ought to be ſlackened at certain times, and at other times to be kept hard, in order to diſappoint him from continually preſſing upon the bit. This facility, or liberty, of the horſeman, of ſlackening or ſtiffening the hand, makes what they call a *good hand*. A horſe is ſaid to *force the hand*, when he does not fear the bridle, but runs away in ſpite of the rider.

To *work the horſe upon the hand*, is to manage him by the effects of the bridle, without any other helps, except the calves of the legs.

To be *heavy upon the hand*, is underſtood of a horſe, which on account of the ſoftneſs of his neck, the weakneſs of his back, the largeneſs of his head, and the weight of his fore-quarters, or his wearineſs, throws himſelf upon the bridle, without making any reſiſtance, or effort, to force the horſeman's hand.

To make a horſe right upon the hand, and free in the *ſtay* or *reſt*, he muſt be taught to know the hand by degrees, and by gentle methods; the horſeman muſt turn him, or change *hands*: ſtop him, and manage with dexterity the *appui*, or preſſure of his mouth, ſo as to make him ſuffer chearfully and freely the effect of the bit-mouth, without reſiſting or reſting heavy upon the hand. The ſhort, or hand-gallop, teaches horſes to be right upon the hand.

Hand, in *Rural Economy*, the name of a meaſure which is employed in aſcertaining the height of horſes, and ſome other ſorts of animals. It is the meaſure of the hand when clenched or ſhut up. A good ſized horſe is from fifteen to ſixteen hands in height; but there are many horſes that are much higher.

Hand is alſo found, in many other terms, or phraſes of art, belonging to the manege, as,

Hand, *to ſlack, or yield the*, is to ſlacken the bridle.

Hand, *to hold up, or ſuſtain the*, is to pull the bridle in.

Hand, *to guide a horſe by the*, is to turn or change hands upon one tread.

Hand, *appui, or ſtay of the*. See Appui.

Hand, *beat upon the*. See Beat and Check.

Hand, *to preſs upon the*. See Press.

Hand, *to change the*. See Change.

Hand, *effects of the*. See Effects.

Hand, *haſten the*. See Haste.

Hand, *to feel a horſe upon the*. See Feel.

Hand, *full, or full reſt upon the hand*. See Appui and Mouth.

HAND, *to have mares covered in the.* See HORSE and MARE.

HAND, *to make a horſe part from the*, or ſuffer him *to ſlip from the hand*, is to put on at full ſpeed.

HAND, *to make a horſe part right from the*, he ſhould not put himſelf upon his back or reins, but bring down his hips.

HANDS, *all.* A horſe is ſaid to turn upon *all hands*, that is not reſty for one hand. This is called in French *entire.*

HAND, *harmonical*, in *Muſic*, uſed by old writers on the elements of the art, for the ancient diagram, or ſcale of muſic, marking the ſolmiſation on the joints of the fingers on the left hand. See *Muſic* PLATES.

It has been ſuppoſed that this was Guido's method of teaching the boys of his convent to ſing. But no proof can be found, in the writings of Guido, that the harmonic hand was of his conſtruction; writers however mention it by the name of the Guidonian hand, ſoon after his time. And, when his ſyſtem was digeſted, and the hexachords were arranged, to teach the names of the notes by the joints of the fingers of the left hand ſeems to have been a common expedient; in which, however, the ſyllabic names of the notes do not follow in an order ſufficiently regular or remarkable to be of much uſe in forming the hexachords, or diſcriminating the mutations. Such an expedient would have been more clear and uſeful in teaching the tetrachords, by appropriating a finger to each of the five, in the great ſyſtem, or diſdiapaſon of the Greeks. And by imagining the five fingers of each hand to repreſent the five lines and ſpaces of the baſe and treble clefs, children may likewiſe be taught to name the notes in the ſcale much ſooner than ſolmiſation by the harmonic hand. Henry Faber has arranged the notes in the harmonic, or Guidonian hand, in a better manner than any other author within our knowledge, by placing a clef at the top of the three middle fingers, as beacons or land-marks, and making each finger the repreſentative of a tetrachord. D'Avella exhibits a great number of harmonic hands, in which the notes of the ſcale are differently diſpoſed; one of the hands, we know not why, he calls Boethian, another he gives to Plato, and a third to Ariſtotle. See HEXACHORDS, SOLMISATION, and D'AVELLA.

HAND *of juſtice*, is a ſceptre, or batoon, a cubit long, having an ivory hand at the extremity thereof; uſed as an attribute of certain kings, wherewith they are painted in their royal robes; as on the coronation day.

Authors uſually call it *virga*. Louis X. of France firſt took the hand of juſtice for his device.

HANDS, *impoſition of*, or *laying on of hands*, ſignifies the conferring of holy orders; a ceremony wherein the hands are laid on the head of another, as a ſign of a miſſion, or of a power given him to exerciſe the functions of the miniſtry belonging to the order.

The apoſtles began to appoint miſſionaries by the impoſition of hands. See IMPOSITION.

HANDS, *waſhing one's*, of a thing ſignifies the witneſſing that a perſon has no part or concern in an affair; and that he will not be anſwerable for it: this Pilate did in reſpect of our Saviour's death. In this ſenſe, a man is ſaid to have *clean hands*; becauſe the hands are the chief inſtruments of action; and particularly a judge does this, to denote that he has not been corrupted by bribes or preſents.

HAND *boating*, in *Agriculture*, a term uſed in ſome places provincially to ſignify the operation of paring the ſward, for the purpoſe of burning, with a beating axe, which is made in the form of a large adze.

HAND-*gallop*, a kind of ſhort gallop, which is very eaſy to the horſe and rider.

HAND-*glaſſes*, in *Gardening*, are all ſuch glaſſes as are moved by the hand, and uſed for placing over, protecting, and forwarding various ſorts of plants, during the winter ſeaſon, ſuch as young cauliflowers, lettuces, &c. and in raiſing ſeedling plants of both theſe ſorts in the ſpring, as well as ſeveral others, in hot-beds, or in warm borders; alſo ſmall ſallading. They are particularly neceſſary in the culture of general crops of ſummer cucumbers, for placing upon the hot-bed ridges made in April and May; and alſo occaſionally for melon-ridges, made in the ſame ſeaſon, to produce crops of autumnal fruit. In the flower-garden, pleaſure-ground, nurſery, green-houſe, &c. they alſo prove very uſeful in propagating, raiſing, and protecting many kinds of curious plants in their young growth, and while they are ſtriking root.

Theſe glaſſes may be employed likewiſe in raiſing many of the tenderer or more curious annual flowers, ſuch as African and French marigolds, chryſanthemums, balſams, ten-week ſtocks, and others of ſimilar kinds, where better contrivances are not at hand for the purpoſe. See ANNUAL PLANTS.

They are ſtill further uſeful in ſtriking many ſorts of ſmall cuttings, pipings, and ſlips of tender or curious plants, ſuch as myrtles, flowering plants, and many other ſimilar kinds.

It may be noticed, that hand-glaſſes are of different kinds and forms. The leaded glaſſes conſiſt of many ſmall panes of glaſs worked into lead-work in different ways.

They are moſtly made ſquare, but ſometimes round or octagonal; in all of which, each is formed in an open frame-work of ſtrong window-lead, and ſometimes of caſt-iron in the ſame form, but more commonly lead; the lower part being upright, from ſix to eight or ten inches in depth, and the other hipped off, or ſloped on each ſide, narrowing upward, ſo as to terminate in a point, as it were, at top, having in that part a fixed erect ring handle of the ſame material; the glaſs being laid in lead-work, and the joints well bruſhed over with proper cement, to render the whole wind and water tight, as well as to prevent the injury of the atmoſphere: and they are of different dimenſions, from twelve or eighteen inches to two feet wide, or more, to ſuit different purpoſes; though for general uſe in kitchen gardens, about eighteen inches width is the moſt common, and nearly the ſame in depth in the whole; but ſome for particular uſes are of ſmaller ſizes, as from ſix or eight to ten or twelve inches in width.

Where laid in frames of caſt-iron, in putty, they are neat, ſtrong, and durable; but heavy, and much more expenſive than leaded glaſſes in general.

There are other ſorts, as what are called *bell* hand-glaſſes, which are blown at the glaſs-houſes in different places, and are equally eligible, or ſuperior to the leaded glaſſes in many caſes, eſpecially in kitchen-gardens, particularly for the preſervation of plants in winter, ſuch as early crops of cauliflowers, deſigned to ſtand the winter, lettuces, &c. as well as for hot-bed ridges of cucumbers and melons, in the ſummer and autumn crops; and theſe are in dimenſions nearly in proportion to thoſe of the larger ſizes of leaded glaſſes, or rather wider below; made in the bell form, having a rough knob at top, ſerving as a handle; they ſhould be made not too high, but flat, and in the dome-form above, which is more advantageous in promoting a ſtrong growth, and not ſo liable to draw up the plants, while they receive the benefit of the ſun more effectually in them.

But

But the leaded glaſſes are ſuperior in this reſpect, that when any of the glaſs-work is broken it can be readily mended, or replaced by the glazier: but the bell-glaſſes, when much broken, are nearly uſeleſs; though, when they are broken into pieces, they may be joined with a cement of ſtrong white-lead, and placed under cover till it is thoroughly dry; and then, with care in handling, they may laſt a long time. As new bell-glaſſes are more liable to crack by froſt, or by too haſtily moving them, than older ones ſeaſoned to the weather, in uſing them the firſt winter in crops of early cauliflowers, &c. great care ſhould be taken in handling them, in lifting them off and on, or in raiſing one ſide occaſionally for the admiſſion of air: the ſeaſoned old found glaſſes are in this reſpect more valuable than the new ones.

All the leaded glaſſes ſhould have wooden frames at the bottom part to reſt upon, otherwiſe they are ſoon deſtroyed by their conſtant contact with the earth, while they are in uſe.

In gardening, it is eſſential to have plenty of theſe different deſcriptions of hand-glaſſes, in order that the various kinds of the more tender culinary crops may be properly protected and brought forward during the more cold and ſevere periods of the winter ſeaſon.

Hand-*hind*, a term ſignifying the hind quarters of a horſe.

Hand-*hoe*, in *Agriculture*, the name of a tool of the hoe kind, which is uſually wrought by the hand. See Hoe.

Hand-*hoeing*, that method of hoeing which is executed by means of hand labour. See Hoeing.

Hand-*mattock*, the name of a tool of the pick-axe kind, which has been lately much recommended for the purpoſe of clearing the ground in ſowing or ſetting acorns among the young trees in plantations.

The deſcription of it is this: the handle is eighteen inches long and the head about fifteen, having one end of it reſembling an adze four inches and a half in breadth in the face; and the other, a pick about ten inches in length tapering, and ſharpened at the point. The axe part is capable of cutting at right angles with the handle in uſing it.

Hand-*reaping*, a term ſignifying the ordinary method of reaping by the hand, in contradiſtinction to that which is practiſed by the ſcythe.

Hand-*reaping Machine*, the name of a tool that has been occaſionally tried in the buſineſs of reaping grains, but without much ſucceſs. See Reaping *Machine*.

Hand-*threſhing Machine*, the name of a machine which is uſed in threſhing out grain, and which is wrought by the hand. See Threshing-*Machine*.

Hand-*weeding*, the method of weeding and cleaning land by means of the hand. See Weeding.

Hand, *Left*. To marry with the left hand, is to eſpouſe a woman of inferior degree, whoſe children, in virtue of ſuch marriage, are not to ſucceed to the father, nor ſhare with the other children, but are to be contented with what fortune the huſband ſhall appoint them the next day after marriage.

This method of taking left-handed wives obtains at this time in Germany.

Hand is alſo uſed for the index of a clock, watch, or the like, ſerving to point the hour, &c.

Hand, *Long*, *Longimanus*, a kind of title, or ſurname, aſſumed by certain princes. Artaxerxes, the ſon of Xerxes, and his ſucceſſor in the Perſian empire, was thus denominated; as having hands ſo long, that he could touch his knees with them when he ſtood upright.

Hand, *Short*. See Tachygraphy.

Hand, *Bloody*. See Bloody *Hand*.

Hand is alſo figuratively uſed in painting, ſculpture, &c. for the manner, or ſtyle, of this or that maſter.

Hands are borne in coat-armour, *dexter* and *ſiniſter*; that is, right and left; expanded or open; and after other manners.

Azure, a dexter hand couped to the wriſt, and extended in pale argent, is borne by the name of Brome. Argent, three ſiniſter hands, couped to the wriſt, gules, by the name of Maynard.

Knights baronets are to bear in a canton, or in an eſcutcheon as they pleaſe, the arms of Ulſter; *viz.* in a field argent, a ſiniſter hand couped to the wriſt, gules. See Baronets.

Hand, or *Handing*, in the *Sea Language*. When a thing is to be delivered away, or paſſed from one to another, or to be brought to any one, then the word is, *hand* it this way, or that way. Alſo, when more men are wanted to do any labour, as hoiſing, &c. they call for more *hands*, not more men.

Handing the ſails is the ſame operation as *furling* them.

Hand, *in and out*, in our *Old Writers*, the name of an unlawful game, now diſuſed and prohibited by the ſtatute 17 Edw. IV. cap. 2.

Hand-*barrow*, in the *Military Art*, is commonly made of hard light wood. It is of great uſe in fortification, for carrying earth from one place to another, and in a ſiege, for carrying bombs, or cannon-ball, along the trenches, and for ſeveral other uſes.

Hand-*borow*, a pledge, or ſurety, of the lower rank.

"Eſt quaſi vas, aut ſidejuſſor manuenſis, hoc eſt, minor, ſeu inferior; nam head-borow, vas eſt capitalis, vel ſuperior." Spelman. See Headborough.

Hand-*breadth*, is ſometimes uſed for a meaſure of three inches.

Hand-*cuffs*, an inſtrument formed of two circular pieces of iron, each fixed by a hinge on the ends of a ſhort iron bar, which being locked over the wriſts of a malefactor, prevents his uſing his hands.

Hand *Grenades*. See Granado.

Hand-*over-hand*, in *Sea Language*, is an order to the men, who pull upon any rope, to paſs their hands alternately one before, or above the other, if they are hoiſing, in order to haſten the ſervice. A ſailor is ſaid to go aloft, *hand-over-hand*, when he aſcends into the tops by a ſingle rope, as a ſhroud or back-ſtay, without the help of the rattlings, by the dexterity of throwing one hand above the other, and lifting his weight along with it.

Hand-*ſale*, in *Law*. See Sale.

Hand-*ſcrew*. See Jack.

Hand-*ſpike*, or *hand-ſpec*, a lever, or piece of aſh, elm, or other ſtrong wood, five or ſix feet long, cut thin like a wedge at one end, that it may get the eaſier betwixt things which are to be ſeparated, or under any thing that is to be raiſed; it is better than a crow of iron, becauſe its length allows a better poiſe.

Hand-ſpikes are uſed in ſhips, to traverſe the ordnance, to heave with in a windlaſs, to weigh up the anchor, &c. The gunners hand-ſpike is ſhorter and flatter than the other, and armed with two claws, for the purpoſe of managing the artillery in battle, &c.

Hand, or *Handful*, is a meaſure of four inches, by the ſtandard; according to the ſtatute 33 Hen. VIII. cap. 5. The hand, among *Jockeys*, is four fingers breadth, and is the meaſure of the fiſt clenched; by this the height of horſes is meaſured.

A horſe for war ſhould be 16 or 18 hands high.

A handful

A *handful* of corn or bran is alſo underſtood to be as much grain or bran as two hands will hold, when joined together; a quantity frequently ordered to be given horſes.

HANDA, or HENDA, in *Geography*, a ſmall inhabited iſland of Scotland, on the coaſt of Sutherland, divided from the main land by a narrow ſound. It riſes gradually from the ſea by a gentle aſcent from the ſouth, and on the north is a tremendous rock, about 80 fathoms in height. It is a mile ſquare, and much freqnented by ſea-fowls of various kinds.

HANDEL, GEORGE FREDERICK, in *Biography*, the greateſt muſical compoſer of his time, and, in ſome particulars, of any time or country in Europe, was born at Halle, in the duchy of Magdeburgh, and circle of Lower Saxony, 24th February, 1684; his father was an eminent ſurgeon and phyſician of the ſame place, and upwards of ſixty years of age when this ſon, the iſſue of a ſecond marriage, was born; and in his early childhood, he diſcovered ſuch a paſſion for muſic as could not be ſubdued by the commands of his father, who intended him for the profeſſion of the law.

He had made a conſiderable progreſs in this art, by ſtealth, before he was allowed a maſter; but at ſeven years old, his father finding it impoſſible to fix his attention to any thing but muſic, for which he ſeemed to have been endowed by nature with very uncommon propenſities and faculties, he placed him under Zachau, organiſt of the cathedral church of Halle; a man of conſiderable abilities in his profeſſion, and proud of his pupil. By the time he was nine years old, our young muſician was not only able to officiate on the organ for his maſter, but began to ſtudy compoſition; and at this early period of his life he is ſaid to have compoſed a Service, or, as it is called in Germany, a *ſpiritual Cantata*, every week, for voices and inſtruments, during three years ſucceſſively. The late Mr. Weideman was in poſſeſſion of a ſet of ſonatas, in three parts, which Handel compoſed when he was only ten years old.

He ſeems to have continued to ſtudy under his firſt maſter Zachau, in his native city, till the year 1698; when, being arrived at the age of fourteen, he was carried to Berlin, where operas were in a very flouriſhing ſtate, at the court of the elector of Brandenburg, afterwards king of Pruſſia, who had then in his ſervice not only many ſingers of eminence from Italy, but Bononcini and Attilio, to compoſe. Handel is ſaid to have diſtinguiſhed himſelf in this city as a wonderful performer, for his early years, and to have given birth to ſuch expectations of his future greatneſs, that his electoral highneſs offered to take him into his ſervice, and ſend him to Italy, for the completion of his muſical ſtudies; but his father declining this honour, from a ſpirit of independence, it was determined that he ſhould return to Halle, where he muſt have continued a conſiderable time; though we are told that his father's death happening ſoon after his return from Berlin, Handel, not being able to ſupport the expence of a journey to Italy, whither he was ambitious of going, removed to Hamburgh, in order, by his muſical talents, to procure a ſubſiſtence: this city, next to Berlin, being then the moſt renowned for its operas. We loſe ſight, however, in all the accounts of his life hitherto publiſhed, both of our young muſician and his improvements from the time of his quitting Berlin, till his arrival at Hamburgh, a period of five years; for, according to his rival Mattheſon, he did not viſit that city till the year 1703, at the age of nineteen.

Yet the celebrated Telemann, one of the greateſt German muſicians of his time, in a well-written account of his own life and works, drawn up by himſelf at the requeſt of Mattheſon, in the year 1740, furniſhes two or three incidents concerning Handel, which intervened between the time of his quitting Berlin and arrival at Hamburgh, that will help to throw a little light on this dark period of his hiſtory.

Telemann, born at Magdeburg 1681, like Handel, diſcovered an early paſſion for muſic, and, while he was at ſchool, had, like him, made a great progreſs in the art, contrary to the inclination of his friends; but, though he played on almoſt every kind of inſtrument, and had attempted to compoſe an opera at twelve years old, yet, in obedience to his mother's poſitive commands, on whom, as his father was dead, he was ſolely dependent, at about the age of twenty he ſolemnly renounced his muſical purſuits, though with the greateſt reluctance, and ſet out for Leipſic, in order to ſtudy the law in that univerſity. In the way thither, however, he ſtopped at Halle, where, ſays Telemann, "from my acquaintance with Handel, who was already famous, I again ſucked in ſo much of the poiſon of muſic as nearly overſet all my reſolutions."

Handel was now but ſixteen years of age; and as Telemann, in his account of himſelf and his ſtudies, ſoon mentions our juvenile muſician again, we ſhall proceed a little further in his narrative.

"However," continues Telemann, "after quitting Handel, I perſevered in the plan preſcribed by my mother, and went to Leipſic to purſue my ſtudies; but, unfortuately, was lodged in a houſe where I perpetually heard muſic of all kinds, which, though much worſe than my own, again led me into temptation. And a fellow-ſtudent finding among my papers a pſalm which I had ſet to muſic, and which, in ſacrificing all my other illicit attempts at compoſition, had chanced to eſcape oblivion, he begged it of me, and had it performed at St. Thomas's church, where it was ſo much approved, that the burgomaſter deſired I would compoſe ſomething of this kind every fortnight; for this I was amply rewarded, and had hopes, likewiſe, given me, of future advantages of much greater importance. At this time I happened to be reminded of the ſolemn promiſe I had made my mother, for whom I had a great reverence, of utterly abandoning all thoughts of muſic, by receiving from her a draught for my ſubſiſtence; which, however, I returned; and, after mentioning the profitable and promiſing ſtate of my affairs, earneſtly intreated her to relax a little in the rigour of her injunctions concerning the ſtudy of muſic. Her bleſſings on my new labours followed; and now I was half a muſician again.

"Soon after I was appointed director of the opera, for which I compoſed many dramas, not only for Leiptic, where I eſtabliſhed the college of muſic which ſtill ſubſiſts, but for Sorau, Frankfort, and the court of Weiſſenfels. The organ of the new church was then juſt built, of which I was appointed organiſt and director of the muſic. This organ, however, I only played at the conſecration, or opening, and afterwards reſigned it, as a bone of contention for young muſical ſtudents to quarrel and ſcramble for. At this time the pen of the excellent Kuhnau ſerved me for a model in fugue and counterpoint; but in faſhioning ſubjects of melody, Handel and I were continually exerciſing our fancy, and reciprocally communicating our thoughts, both by letters and converſation, in the frequent viſits we made to each other."

According to Telemann's dates, all this muſt have happened between the years 1701 and 1703, when Handel, quitting Halle, arrived at Hamburgh, a place too diſtant from Leipſic for frequent viſits between theſe young muſicians to have been practicable.

Mattheſon's early connection and intercourſe there with Handel,

Handel, before his name as a great muſician had penetrated into other parts of Europe, were ſuch, that it is hopeleſs now to ſeek for better information than his writings furniſh, concerning ſo intereſting a period.

Mattheſon was a vain and pompous man, whoſe firſt wiſh in all his writings was to impreſs the reader with a due reverence for his own abilities and importance. It was his boaſt before his death, in 1764, at the age of eighty-three, "that he had printed as many books, on the ſubject of muſic, as he had lived years; and that he ſhould leave to his executors an equal number, in manuſcript, for the uſe of poſterity."

In 1761, he publiſhed a Tranſlation of the Life of Handel, from the Engliſh; with additions and remarks, which are neither very candid nor liberal. But how ſhould the author of that book expect quarter from him, in which it is aſſerted, that "Mattheſon was no great ſinger, and only employed occaſionally." In refutation of which he aſſures us, "that he conſtantly ſung the principal parts in the Hamburgh operas, during fifteen years, and with ſuch ſucceſs, that he could command the paſſions of his audience, by exciting in them, at his pleaſure, joy, grief, hope, and fear." And who ſhall venture to doubt of his having poſſeſſed theſe powers, when their effects are thus atteſted *by himſelf?* And in a work of muſical biography and criticiſm, by Mattheſon, called *Grundlage einer Ehren-Pforte*, Foundation of a triumphal Arch, in honour of muſic and muſicians, publiſhed at Hamburgh 1740, in which there is a long and inflated account of himſelf and his works, which occupies thirty pages, we have, as well as in his annotations on the Engliſh Life, a more ample and ſatisfactory account of Handel's juvenile compoſitions and adventures, than we have been able to find elſewhere.

After telling us that he arrived at Hamburgh in the ſummer of 1703, rich in genius and good diſpoſition: "Here," ſays Mattheſon, "almoſt his firſt acquaintance was myſelf; as I met with him at the organ of St. Mary Magdalen's church, July the 30th, whence I conducted him to my father's houſe, where he was treated with all poſſible kindneſs as well as hoſpitality; and I afterwards not only attended him to organs, choirs, operas, and concerts, but recommended to him ſeveral ſcholars, particularly to one in a certain houſe, where every body was much devoted to muſic.

"At firſt he only played a *ripieno* violin in the opera orcheſtra, and behaved as if he could not count five; being naturally inclined to dry humour.

"At this time he compoſed extreme long airs and cantatas without end; of which, though the harmony was excellent, yet true taſte was wanting; which, however, he very ſoon acquired by his attendance at the opera."

As theſe young muſicians lived much together in great intimacy, they had frequent amicable conteſts and trials of ſkill with each other; in which it appearing that they excelled on different inſtruments, Handel on the organ, and Mattheſon on the harpſichord, they mutually agreed not to invade each other's province, and faithfully obſerved this compact for five or ſix years.

Mattheſon tells us, that in the year 1704, the opera-houſe at Hamburgh happening to be ſhut, leaving Handel behind him, he travelled to Holland, played on the famous organs, and heard the great performers in that country; made concerts at Amſterdam, and might have been elected organiſt of Haerlem; having had an offer of that place, with a ſalary of fifteen hundred Dutch goldens, equal to near a hundred and fifty pounds ſterling a year.

Handel, at this time, muſt have been compoſing his firſt opera. Mattheſon in his remarks on the Life of Handel, is particularly ſevere on that part of it which contains an account of the quarrel which happened between him and that compoſer, ſoon after the letter was written; accuſing the biographer not only of violating geography, chronology, and hiſtory, but of a wilful miſrepreſentation of facts, in relating the circumſtances of this breach between them.

This writer, with great ſelf-complaiſance and pedantry, is generally allowed to have been diligent in finding, and exact in ſtating facts, after telling us that Handel, when he firſt came to Hamburgh, notwithſtanding the exalted ſtation at which he ſoon arrived, had no better part aſſigned him in the opera, than the *ſecond ripieno violin*; informs us, that "though he then pretended to know nothing, yet he uſed to be very arch, for he had always a dry way of making the graveſt people laugh, without laughing himſelf. But his ſuperior abilities were ſoon diſcovered, when, upon occaſion of the harpſicord player at the opera being abſent, he was firſt perſuaded to take his place; for he then ſhewed himſelf to be a great maſter, to the aſtoniſhment of every one, except myſelf, who had frequently heard him before, upon keyed-inſtruments."

According to Mattheſon's own confeſſion, he acquired from Handel, by frequently meeting him at his father's houſe, and practiſing with him, a knowledge of modulation, and method of combining ſounds, which he could have learned of no one elſe.

About this time an opera, called "Cleopatra," compoſed by Mattheſon, was performed on that ſtage, in which he acted the part of Anthony himſelf, and Handel played the harpſichord; but Mattheſon being accuſtomed, upon the death of Anthony, which happens early in the piece, to take the harpſichord, in the character of compoſer, Handel refuſed to indulge his vanity, by relinquiſhing to him this poſt; which occaſioned ſo violent a quarrel between them, that at going out of the houſe, Mattheſon gave him a ſlap on the face; upon which, both immediately drew their ſwords, and a duel enſued in the market-place, before the door of the opera-houſe; luckily, the ſword of Mattheſon was broke againſt a metal button upon Handel's coat, which put an end to the combat, and they were ſoon after reconciled.

Such is the account, which, long before the death of Handel, Mattheſon himſelf publiſhed, concerning the difference that happened between them during his reſidence at Hamburgh.

This rencontre happened the 5th of December, 1704; and, as a proof of a ſpeedy reconciliation, Mattheſon tells us, that on the 30th of the ſame month, he accompanied the young compoſer to the rehearſal of his firſt opera of "Almira," at the theatre, and performed in it the principal part; and that, afterwards, they became greater friends than ever. This opera, though rehearſed at the end of 1704, was not publicly performed till the beginning of 1705, when it was greatly approved.

On the 25th of February of the ſame year, he produced his ſecond opera, called "Nero," which had likewiſe a very favourable reception.

From 1705 to 1708, when Handel ſet two other operas, "Florindo" and "Daphne," he furniſhed nothing for the ſtage; though he had many ſcholars, compoſed harpſichord-pieces, ſingle ſongs, and cantatas, innumerable.

During his reſidence at Hamburgh, Mattheſon allows, that Handel improved his own ſtyle greatly, by his conſtant attendance at the opera; and ſays, that he was even more powerful upon the organ, in extempore fugues and counter-point,

point, than the famous Kuhnau of Leipſic, who was at this time regarded as a prodigy.

Handel having acquired by his operas at Hamburgh a ſum ſufficient to enable him to viſit Italy, ſet out for that ſeat of the Muſes, a journey after which every man of genius ſo ardently pants. He ſtaid ſome time at Florence, where he compoſed the opera of "Rodrigo." From this city he went to Venice, where, in 1709, he produced his "Agrippina," which is ſaid by his biographer to have been received with acclamation, and to have run thirty nights. Here he met with Domenico Scarlatti, Gaſparini, and Lotti.

The next place he viſited was Rome, where he had an opportunity of hearing compoſitions and performers of the firſt claſs. Here the elder Scarlatti and Gaſparini had brought vocal muſic to great perfection, and Corelli, inſtrumental. At cardinal Ottoboni's, by whom Handel was greatly careſſed and patronized, he had frequently the advantage of hearing the natural and elegant Corelli perform his own works. Here our young compoſer produced a ſerenata, "Il Trionfo del Tempo;" (the original ſcore of this work is in his majeſty's collection;) after which he proceeded to Naples, where he ſet "Acis and Galatea," in Italian, to muſic, totally different from the little Engliſh drama, written by Gay, which he ſet in 1721, for the duke of Chandos.

When he returned to Germany, on quitting Italy, at the latter end of 1709, or the beginning of 1710, the firſt place at which he ſtopped was Hanover; where he found a munificent patron in the elector, who afterwards, on the death of queen Anne, aſcended the Engliſh throne, by the name of George the Firſt. This prince had in his ſervice, as maeſtro di cappella, the elegant and learned compoſer Steffani, whom Handel had met before at Venice, and who now reſigned his office of maeſtro di cappella to the elector, in his favour. This venerable compoſer ſerved him as a model for the ſtyle of chamber duets, as well as facilitated his introduction to the ſmiles of his patron, the elector, who ſettled on him a penſion of 1500 crowns, upon condition that he would return to his court, when he had completed his travels. Handel, acceding to this propoſition, went to Duſſeldorp, where he had a flattering reception from the elector palatine, who, likewiſe, wiſhed to retain him in his ſervice. But beſides the engagement into which he had entered with the elector of Hanover, he was impatient to viſit England, where a paſſion for dramatic muſic had already manifeſted itſelf in ſeveral awkward attempts at operas, and to which place he had received invitations from ſeveral of the nobility, whom he had ſeen in Italy and Hanover.

It was at the latter end of the year 1710, that he arrived in England; his reception was as flattering to himſelf as honourable to the nation, at this time no leſs ſucceſsful in war, than in the cultivation of the arts of peace. To the wit, poetry, literature, and ſcience, which marked this period of our hiſtory, Handel added all the blandiſhments of a nervous and learned muſic, which he firſt brought hither, planted, and lived to ſee grow to a very flouriſhing ſtate.

The firſt compoſition which he produced in England, was his famous opera of "Rinaldo," performed in March 1711, and Handel is ſaid in the preface to have ſet it to muſic *in a fortnight*. This opera, in which the celebrated Nicolini and Valentini, the firſt Italian ſingers that appeared on our ſtage, performed; was the delight of the nation during many years; as it was revived in 1712, 1717, and 1731.

After remaining about a year in this country, and eſtabliſhing a great reputation on the ſolid baſis of the moſt exalted and indiſputable merit, both as a compoſer and performer, he returned to Hanover, on a promiſe made to his moſt powerful Engliſh friends to reviſit this kingdom again, as ſoon as he could obtain permiſſion of his electoral highneſs and patron. About the end of the year 1712, this permiſſion was granted for a limited time. And we find his "Paſtor Fido," and "Theſeus," in the liſt of Italian operas, brought on the Engliſh ſtage, this and the following year: and in 1715, "Amadige," or "Amadis of Gaul."

Not long after this ſecond arrival in London, the peace of Utrecht having been brought to a concluſion, Handel was preferred to all others, ſeemingly without a murmur from native muſicians, to compoſe the hymn of gratitude and triumph on the occaſion. Envy, though outrageous and noiſy at the ſucceſs of comparative abilities, is ſtruck dumb and blind by exceſs of ſuperiority. The grand "Te Deum" and "Jubilate," which he ſet on this occaſion, were compoſed with ſuch force, regularity, and inſtrumental effects, as the Engliſh had never heard before. Purcell's "Te Deum," in deſign, and expreſſion of the words, is, perhaps, ſuperior to all others; but in grandeur and richneſs of accompaniment, nothing but national partiality can deny Handel the preference. The queen ſettled on him for life a penſion of two hundred pounds per annum. And all who had heard Rinaldo, wiſhed him again employed for the opera; ſo that the multiplicity of buſineſs, and the many protectors and friends he met with in England, a little impaired the memory of our great compoſer with reſpect to continental connections; and he ſeemed to think of nothing leſs than returning to Hanover till after the death of queen Anne, in 1714, when his majeſty, George I. arriving in England, ſaved him the trouble of a German tour.

Handel, conſcious of his deficiency in reſpect and gratitude to a prince who honoured him with ſuch flattering marks of approbation and bounty, durſt not approach the court, till by the ingenuity and friendly interpoſition of baron Kilmanſegge, he was reſtored to favour in the following manner: The king, ſoon after his arrival in theſe kingdoms, having been prevailed on to form a party on the water, the deſign was communicated to Handel, who was adviſed to compoſe ſome pieces expreſsly for the occaſion; the performance of which he ſecretly conducted in a boat that accompanied the royal barge. Upon hearing theſe compoſitions, which have been ſince ſo well known, and ſo juſtly celebrated under the title of the "Water-Muſic," his majeſty, equally ſurpriſed and pleaſed by their excellence, eagerly enquired who was the author of them; when the baron acquainted the king that they were the productions of a faithful ſervant of his majeſty, who, conſcious of the cauſe of diſpleaſure which he had given to ſo gracious a protector, durſt not preſume to approach his royal preſence, till he had aſſurances that by every poſſible demonſtration of duty and gratitude in future, he might hope to obtain a pardon. This interceſſion having been graciouſly accepted, Handel was reſtored to favour, and his compoſitions honoured with the moſt flattering marks of royal approbation. And as a ratification of the delinquent's peace, thus eaſily obtained, his majeſty was pleaſed to add a penſion of two hundred pounds a year to that which had been previouſly conferred on him by queen Anne; and not many years after, when he was employed to teach the young princeſſes, another penſion of the ſame value was added to the former grants, by her majeſty queen Caroline.

From the year 1715 to 1720, we find in the records of the Muſical Drama, no new opera that was ſet by Handel. The firſt three years of this period were chiefly ſpent at the earl of Burlington's, a nobleman, whoſe taſte and judgment in

in the fine arts were as exquiſite as his patronage to their votaries was liberal. And during the other two years, Handel ſeems to have been employed at Cannons, as maeſtro di capella to the duke of Chandos; who, among other ſplendid and princely kinds of magnificence, eſtabliſhed a chapel, in which the cathedral ſervice was daily performed by a choir of voices and inſtruments, ſuperior, at that time, perhaps, in number and excellence, to that of any ſovereign prince in Europe. Here Handel produced, beſides his anthems, the chief part of his hautbois concertos, ſonatas, leſſons, and organ fugues; which are all ſo maſterly, ſpirited, and exquiſite in their ſeveral kinds, that if he had never compoſed an opera, oratorio, Te Deum, duet, cantata, or any other ſpecies of vocal muſic, his name would have been held in reverence by true muſicians, as long as the characters in which they are written ſhould continue to be legible.

We come now to the buſieſt and moſt glorious period of Handel's life; who, arrived at that ſtage of exiſtence which Dante calls

"Il mezzo del cammin di noſtra vita;"

when the human frame and faculties have acquired their utmoſt ſtrength and vigour; was endowed with great natural powers, highly improved by cultivation; with a hand which no difficulties could embarraſs; a genius for compoſition unbounded; at the head of a profeſſion which facilitates acceſs to the great, and, with extraordinary abilities, enſures their patronage; high in the favour of the ſovereign, nobles, and public, of a great and powerful nation, at a period of its greateſt happineſs and tranquillity; when it was not only bleſt with leiſure and zeal to cultivate the arts of peace, but with power, liberally to reward thoſe whoſe ſucceſsful efforts had carried them beyond the bounds of mediocrity.

Such were Handel's circumſtances and ſituation, when a plan was formed, by the Engliſh nobility and gentry, for eſtabliſhing a fund for the ſupport of Italian operas, of which he was to be the compoſer and director; and, as his majeſty king George I. was pleaſed to ſubſcribe one thouſand pounds towards the execution of this deſign, and to let his name appear at the head of the ſubſcription, amounting to fifty thouſand pounds, this ſociety was called the "Royal Academy."

The progreſs and declenſion of this eſtabliſhment, will be found in the account of the COMMEMORATION *of Handel*, and in the articles OPERA, *Ital. of Feuds*, and BONONCINO, we ſhall only obſerve here, that till the year 1727, this academy was ſupported and continued to flouriſh, with the utmoſt ſplendour, delighting the public, and improving our taſte; but by the patrons and partizans of two great female ſingers of diſputable talents, Fauſtina and Cuzzoni, the ſubſcribers were ſo divided in their opinions of the merit of theſe two Sirens, that when the admirers of one of them began to applaud, the others began to hiſs.

A few years after, a quarrel happened between Handel and Seneſino, which broke up the academy, and was not only injurious to the fortune of our great compoſer, but the cauſe of infinite trouble and vexation to him during the reſt of his life.

It is now too late to determine who was the aggreſſor in this long and ruinous war; perhaps Handel exerciſed his power too roughly, and Seneſino was too impatient of control. Perhaps too, the nobility carried their reſentment too far, in ſetting up another opera to the ruin of a man of ſuch uncommon worth and abilities; and, perhaps, if Handel's temper had at all reſembled his finger, in flexibility, a reconciliation might have been effected on no very mortifying or diſhonourable terms. It is painful to dwell on this part of his life, which was one continued tiſſue of loſſes and misfortunes. He produced thirty operas between the years 1721 and 1740; yet, after the diſſolution of the academy, in 1729, none were attended with the ſucceſs that was due to their intrinſic and ſuperior merit, though ſome of the beſt were poſterior to that period. Neglect and oppoſition conſpired to rob him at once of health, fame, and fortune.

In the midſt of opera ſquabbles, while he was oppoſed by the principal nobility and gentry of the Royal Academy, who ſeized on the theatre in the Haymarket, ſupporting an opera without his compoſitions, or the performance of his adherents; when, ſetting up for himſelf, at his own riſk, he engaged the theatre in Lincoln's-inn-Fields, and a new band of ſingers and inſtrumental performers, in order to make head againſt his powerful opponents. It was during this period that Handel, in the year 1732, began the performance of oratorios in the theatre. "Eſther," which he had compoſed for the duke of Chandos, at Cannons, in 1720, was the firſt; "Deborah," the ſecond; and "Athaliah," the third; which was performed in the public theatre at Oxford in 1733, when he opened the organ in ſuch a manner as aſtoniſhed every hearer. The late Mr. Michael Chriſtian Feſting and Dr. Arne, who were preſent, both aſſured us, that neither themſelves, nor any one elſe of their acquaintance, had ever before heard ſuch extempore, or ſuch premeditated playing, on that or any other inſtrument.

It was during theſe early performances of oratorios, that Handel firſt gratified the public by playing concertos on the organ, a ſpecies of muſic wholly of his own invention, in which he uſually introduced an extempore fugue, a diapaſon-piece, or an adagio, manifeſting not only the wonderful fertility and readineſs of his invention, but the moſt perfect accuracy and neatneſs of execution.

In 1740, the oratorio of "Saul" was performed for the firſt time at the theatre in Lincoln's-inn-Fields; and from this period, Handel may be ſaid to have devoted his labours ſolely to the ſervice of the church; as, except his "grand concertos for violins," and the "Fire-work Muſic," for the peace of Aix la Chapelle, 1748; we remember no other compoſitions than oratorios, that were either performed or publiſhed by him.

From 1740, when he totally quitted the opera-ſtage, to 1751, he produced fifteen original oratorios, and adapted Engliſh words to the muſic of a ſerenata, or morality, "Il Trionfo del Tempo," (the Triumph of Time and Truth,) which he had ſet to Italian words at Rome, 1709. Of theſe, the Meſſiah, Samſon, and Judas Macchabæus, were ſure to fill the houſe whenever they were performed; but though the reſt are hazardous, and fluctuating in favour, yet there is no one of them which an exquiſite and darling ſinger, ſuch as Mrs. Sheridan, or Mrs. Bates, could not render important and attractive.

It was after repeated miſcarriages, and a very ſevere illneſs, ſuppoſed to have been brought on by the joint effects of anxiety, mortification, diſtreſs, and diſappointment, that he was driven to the Hibernian ſhore.

Handel remained eight or nine months in Ireland, where he extended his fame, and began to repair his fortune. At his return to London, in the beginning of 1742, as he had relinquiſhed all thoughts of oppoſing the preſent managers of the opera, former enmities began to ſubſide; and, when he recommenced his oratorios at Covent-Garden, the Lent following, he found a general diſpoſition in the public to countenance and ſupport him. Samſon was the firſt he performed this year, which was not only much applauded by crowded houſes in the capital, but was ſoon diſſeminated, in

ſingle ſongs, throughout the kingdom; and, indeed, it has ever been in the higheſt favour of all his oratorios, except the Meſſiah, which this ſeaſon, to the honour of the public at large, and diſgrace of cabal and faction, was received with univerſal admiration and applauſe. And from that time to the preſent, this great work has been heard in all parts of the kingdom with increaſing reverence and delight; it has fed the hungry, clothed the naked, foſtered the orphan, and enriched ſucceeding managers of oratorios, more than any ſingle muſical production in this or any country.

This *Sacred* Oratorio, as it was at firſt called, on account of the words being wholly compoſed of genuine texts of ſcripture, appearing to ſtand in ſuch high eſtimation with the public; Handel, actuated by motives of the pureſt benevolence and humanity, formed the laudable reſolution of performing it annually for the benefit of the Foundling Hoſpital, which reſolution was conſtantly put in practice to the end of his life, under his own direction; and, long after, under that of Mr. Smith and Mr. Stanley. In conſequence of theſe performances, the benefactions to the charity from the years 1749 to 1759, by eleven performances under Handel's own direction, amounted to - £6935 0 0

From 1760 to 1768, by eight performances under the conduct of Mr. John Chriſtian Smith - - - - 1332 0 0

From 1769 to 1777, nine performances under that of Mr. Stanley - - 2032 0 0

£10,299 0 0

The organ in the chapel of this hoſpital was likewiſe a preſent from Handel; and he bequeathed, as a legacy to this charity, a fair copy of the original ſcore of the Meſſiah.

From the period of his quitting Ireland, he continued his oratorios to the time of his death; though late in life, like the great poets Homer and Milton, he was afflicted with blindneſs; which, however it might diſpirit and embarraſs him at other times, had no effect on his nerves or intellects in public; as he continued to play concertos and voluntaries between the parts of his oratorios to the laſt, with the ſame vigour of thought and touch, for which he was ever ſo juſtly renowned. To ſee him, however, led to the organ, after this calamity, at upwards of ſeventy years of age, and then conducted towards the audience to make his accuſtomed obeiſance, was a ſight ſo truly afflicting and deplorable to perſons of ſenſibility, as greatly diminiſhed their pleaſure in hearing him perform.

During the oratorio ſeaſon, we have been told that he practiſed almoſt inceſſantly; and, indeed, that muſt have been the caſe, or his memory uncommonly retentive; for, after his blindneſs, he played ſeveral of his old organ-concertos, which muſt have been previouſly impreſſed on his memory by practice. At laſt, however, he rather choſe to truſt to his inventive powers, than thoſe of reminiſcence; for, giving the band only the ſkeleton, or ritornels of each movement, he played all the ſolo parts extempore, while the other inſtruments left him, *ad libitum*; waiting for the ſignal of a ſhake, before they played ſuch fragments of ſymphony as they found in their books.

Indeed, he not only continued to perform in public, after he was afflicted with blindneſs, but to *compoſe* in private; for we have been aſſured, that the duet and chorus in Judas Macchabæus, of "Sion now his head ſhall raiſe, Tune your harps to ſongs of praiſe," were dictated to Mr. Smith, by Handel, after the total privation of ſight.

The laſt oratorio at which he attended and performed, was on the 6th of April, and he expired on the 13th, 1759.

The figure of Handel was large, and he was ſomewhat corpulent and unwieldy in his motions, and his general caſt of countenance ſeemed rather heavy and ſour; yet, when animated in converſation, his viſage was full of fire and dignity, and ſuch as impreſſed ideas of ſuperiority and genius; and when he ſmiled, there was a ſudden flaſh of intelligence, wit, and good humour beaming in his countenance, which we hardly ever remember to have ſeen in any other.

Though he was generally rough and peremptory in his manners and converſation, he was totally devoid of ill-nature or malevolence; indeed, there was an original humour and pleaſantry in his moſt lively ſallies of anger or impatience, which, with his broken Engliſh, were extremely riſible. His natural propenſity to wit and humour, and happy manner of relating common occurrences, in an uncommon way, enabled him to throw perſons and things into very ridiculous attitudes. Had he been as great a maſter of the Engliſh language as Swift, his *bon mots* would have been as frequent, and ſomewhat of the ſame kind.

Handel, with many virtues, was addicted to no vice that was injurious to ſociety. Nature, indeed, required a great ſupply of ſuſtenance to ſupport ſo huge a maſs, and he was rather epicurean in the choice of it; but this ſeems to have been the only appetite which he allowed himſelf to gratify; and though he was frequently rough in his language, and in the habit of ſwearing, a vice then much more in faſhion than at preſent, he was truly pious during the laſt years of his life, and conſtantly attended public prayers twice a day, winter and ſummer, both in London and Tunbridge.

It has been ſaid of him, that, out of his profeſſion, he was ignorant and dull; but though we do not admit the charge, yet, if the fact was as true as it is ſevere, it muſt be allowed, in extenuation, that to poſſeſs a difficult art in the perfect manner which he did, and to be poſſeſſed by it, ſeems a natural conſequence; and all that the public had a right to expect, as he pretended to nothing more. Accompliſhments can only amuſe our private friends and ourſelves in leiſure hours; but ſo occupied and abſorbed was Handel, by the ſtudy and exerciſe of his profeſſion, that he had little time to beſtow, either on private amuſements or the cultivation of friendſhip. Indeed, the credit and reverence ariſing from theſe, had Handel poſſeſſed them, would have been tranſient, and confined to his own age and acquaintance; whereas, the fame acquired by ſilent and cloſe application to his profeſſional buſineſs,

"——Nec Jovis ira, nec ignes,
Nec poterit ferrum, nec edax abolere vetuſtas."

And it is probable, that his name, like that of many of his brethren, will long ſurvive his works. The moſt learned man can give us no information concerning either the private life or compoſitions of Orpheus, Amphion, Linus, Olympus, Terpander, or Timotheus, yet every ſchool-boy can tell us, that they were great muſicians, the delight of their ſeveral ages, and, many years after, of poſterity.

Though totally free from the ſordid vices of meanneſs and avarice, and poſſeſſed of their oppoſite virtues, charity and generoſity, in ſpite of temporary adverſity, powerful enemies, and freqnent maladies of body, which ſometimes extended to intellect, Handel died worth upwards of twenty thouſand pounds; which, except one thouſand to the fund for decayed muſicians and their families, he chiefly bequeathed to his relations on the continent.

His funeral was not public, like that of Rameau in France; of Jomelli in Italy; or of our Dryden and Garrick in England;

England; yet, when he was buried in Weſtminſter-Abbey, April 20th, 1759, the dean, Dr. Pearce, biſhop of Rocheſter, aſſiſted by the choir, performed the funeral ſolemnity. More general and national teſtimonies of regard and reverence were left to a later period, when all enmities, jealouſies, and operations of envy were ſubſided; and when time, examination, and reflection had given new charms and importance to his works. And this pleaſing taſk was performed in a way ſo ample, magnificent, and honourable, that it will be difficult to find, either in ancient or modern hiſtory, a more liberal and ſplendid example of gratitude to a deceaſed artiſt, in any other country. See account of the COMMEMORATION *of Handel.*

Character of Handel as a Compoſer.—That Handel was ſuperior in the ſtrength and boldneſs of his ſtyle; the richneſs of his harmony, and complication of parts, to every compoſer who has been moſt admired for ſuch excellencies, cannot be diſputed; and, while *fugue*, *contrivance*, and a *full ſcore*, were more generally reverenced than at preſent, he remained wholly unrivalled.

We know it has been ſaid that Handel was not the original and immediate inventor of ſeveral ſpecies of muſic for which his name has been celebrated; but with reſpect to *originality*, it is a term to which proper limits ſhould be ſet before it is applied to the productions of any artiſt. Every *invention* is clumſy in its beginning; and Shakſpeare was not the firſt writer of plays, or Corelli the firſt compoſer of violin ſolos, ſonatas, and concertos, though thoſe which he produced were the beſt of his time; nor was Milton the inventor of epic poetry. The ſcale, harmony, and cadence of muſic being ſettled, it is impoſſible for any compoſer to invent a *genus* of compoſition that is *wholly* and *rigorouſly* new, any more than for a poet to form *a language*, *idiom*, and *phraſeology* for himſelf. All that the greateſt and boldeſt muſical inventor *can* do, is to avail himſelf of the beſt effuſions, combinations, and effects of his predeceſſors; to arrange and apply them in a new manner; and to add, from his own ſource, whatever he can draw, that is grand, graceful, gay, pathetic, or in any other way pleaſing. This Handel did in a moſt ample and ſuperior manner; being poſſeſſed, in his middle age and full vigour, of every refinement and perfection of his time; uniting the depth and elaborate contrivance of his own country with Italian elegance and facility: as he ſeems, while he reſided ſouth of the Alps, to have liſtened attentively in the church, theatre, and chamber, to the moſt exquiſite compoſitions and performers of every kind that were then exiſting.

We will not aſſert that his vocal melodies were more poliſhed and graceful than thoſe of his countryman and contemporary Haſſe; or his recitatives, or muſical declamation, ſuperior to that of his rivals, Bononcini and Porpora. But in his inſtrumental compoſitions there is a vigour, a ſpirit, a variety, a learning, and invention, ſuperior to every other compoſer that can be named; and, in his organ fugues, and organ playing, there is learning always free from pedantry; and, in his choruſes, a grandeur and ſublimity which we believe has never been equalled ſince the invention of counterpoint.

HANDGRITH, in our *Old Writers*, peace or protection given by the king with his own hand. "Hæc mittunt hominem in miſericordia regis, infractio ſeu violatio pacis quam per manum ſuam dabit alicui." Leg. Hen. I.

The word is Saxon, from *hant*, or *hond*, *manus*, and *grith*, *pax*.

HAND-HABEND, in our *Ancient Cuſtoms*, denotes a thief taken in the very fact.

Hand, or *lond-habend*, from the Saxon *lond*, *hand*, and *habend*, *having*, is a circumſtance of manifeſt theft, when the party is taken with the mainor, or mainover, *i. e.* the thing ſtolen, in his hand.

Bracton alſo uſes *hand-berend* in the ſame ſenſe. *Sc. Latro manifeſtus.*

So in Fleta, "Furtum manifeſtum eſt ubi aliquis latro deprehenſus ſeiſitus de aliquo latrocinio hand-habbinde, et backberinde, et inſecutus fuerit per aliquem cujus res illa fuerit, quæ dicitur Sacborgh, et tunc licet inſecutori rem ſuam petere criminaliter ut furatam." Lib. 1. cap. 38. § 1.

HAND-HABEND alſo ſignifies the right which the lord has to judge and determine of this offence in his court.

HANDLESS, in *Mining*, the part of a hand-winding apparatus, or turnſtick and wallower, drewk, turn-bail, turn-barrel, roll and ſpindle, &c. which are uſed on the tops of coal-pits, at right angles to the ſpindle of the barrel, into which the handle is fixed.

HANDLING, a term uſed in reſpect of fighting cocks; ſignifying the meaſuring the girth of them, by griping one's hands and fingers round the cock's body.

HANDLING, in *Painting*, is uſed to deſignate the mode in which a painter lays his colours on his ground; of courſe it has the ſame meaning as the word *Execution* in the ſame art, which ſee.

HANDO, in *Geography*, a country of Africa, ſubject to Quoja.

HANDY-WARP, in our *Old Writers*, a kind of cloth mentioned in ſtat. 4 & 5 Phil. & Mar. cap. 5.

HANDYA, in *Geography*, a town of Hindooſtan, in the circar of Jyenagur; 12 miles E. of Jyepour.

HANEBO, a town of Sweden, in the province of Helſingland; 12 miles S.W. of Soderhamn.

HANEDAK, a town of Nubia, on the Nile; 80 miles N.W. of Dongola.

HANEPARI, a town of Hindooſtan, in the Carnatic; 20 miles N. of Tanjore.

HANG-BENCHES, in *Mining*, ſignify a part of the wooden ſtowres, or hand-winding apparatus, uſed at the ſmaller lead-mines in Derbyſhire.

HANGING *in* CHAINS. See CHAINS.

HANGING *of Gates*, in *Rural Economy*, the mode of fixing them upon their hinges or crooks. See GATE.

HANGING *Knees*, are knees whoſe arms are attached to the ſides of ſhips, in a vertical direction.

HANGING-*ſide*, in *Mining*, ſignifies the up-check or overhanging ſide of a hading vein. M. Werner ſays (tranſlation of his "New Theory of Veins," p. 81.), it happens almoſt always, that the correſponding-ſtrata on the hanging-ſide of a vein are found much lower down than on its laying ſide. This difference of level in the parts of the ſame ſtratum or bed, bears a proportion to the ſize of the vein, being always greateſt in thoſe which are of moſt conſiderable magnitude. Mr. John Williams (Mineral Kingdom, ſecond edition, vol. i. p. 381.), denominates theſe *ſlip-veins*, and ſeems of opinion, that where one ſide of the vein is thus ſunk down, that ſuch veins are generally narroweſt at the top; and yet M. Werner, in the work above-quoted pages 65 and 162, aſſerts generally, "that veins, in proportion as they ſink deep, become narrow, and at laſt terminate in wedges." Too much, of what Mr. Weſtgarth Forſter ſays on the ſubject of veins, in his recent "Treatiſe on a Section of Strata," is copied verbatim from Mr. Williams's work, without acknowledgment, to inſpire much confidence in what he ſays on ſlip-veins. From Mr. Farey's recent examination of the Derbyſhire mines, as detailed in his Report on that county, it does not appear probable that the hanging-ſide in the lading veins there are lower or higher than the other, except

where a fault has broken through the vein, ſince its formation, and introduced rolled pebbles or other extraneous matters into the broken vein.

HANGINGS, linings for rooms, made of arras, tapeſtry, or the like.

HANGLIP, Cape, in *Geography*, a cape on the ſouthern extremity of Africa, and E. ſide of Falſe bay. S. lat. 34° 16′. E. long. 18° 44′.

HANGMAN's Point, a cape of Ireland, at the entrance of Kinſale harbour; two miles S. of Kinſale. N. lat. 51° 47′. W. long. 8° 29′.

HANG-NEST Oriole, and alſo *Hang-neſt* American, in *Ornithology*, the trivial names of the Linnæan Oriolus *nidipendulus*, which ſee.

HANGO, or Ingo, in *Geography*, a ſea-port town of Sweden, in the province of Nyland, on the Baltic; 30 miles W. of Helſinglors. N. lat. 60° 3′. E. long. 23° 56.

HANG-TCHEOU-FOU, or Han-choo-foo, a city of China, the metropolis of the province of Tche-kiang, is one of the richeſt, beſt ſituated, and largeſt cities of the empire, and conſidered by the Chineſe as "the paradiſe of the earth." It is four leagues in circumference, excluſive of its ſuburbs, and the number of its inhabitants, little inferior to thoſe of Pekin, is computed at more than a million.

Its ſituation between the baſin of the great canal, and the river Tſien-tang, which falls into the ſea at the diſtance of about 60 miles to the eaſtward; the tide which at full increaſes the width of this river to about four miles oppoſite the city, and which at low-water leaves a fine level ſtrand about two miles broad, render it the grand emporium for all kinds of merchandize that paſs between the northern and ſouthern provinces. Notwithſtanding its extent, population, manufactures, and trade, its appearance, excepting its walls, is mean. The higheſt houſes are only two ſtories; the ſtreets are narrow but well paved; and the principal of them conſiſt altogether of ſhops and warehouſes, not inferior to thoſe of the moſt ſplendid kind in London. The manufacture of its ſilk and ſatins is chiefly executed by women; and theſe articles, together with furs and Engliſh broad-cloths, occaſion a very brisk and extenſive trade. The ladies, in lieu of linen, wear next them a ſilk netting; over this a waiſtcoat, and drawers of ſilk, lined, in cold weather, with furs; and over all a ſatin robe, neatly gathered round the waiſt, and retained by a ſaſh. The country about this city produces abundance of excellent ſilk; and it is ſaid that 60,000 perſons are employed in the ſurrounding towns and villages. As this place is the capital of the province, it is garriſoned by about 10,000 men, Chineſe and Tartars; and it has under its juriſdiction ſeven cities of the ſecond and third claſs. Several canals are cut to aid the commerce of the town; and it derives great advantage from a lake, about ſix miles in circumference, called "Si-hou," which waſhes its walls on the weſtern ſide, the water of which is pure and limpid, and the banks of which are covered with flowers. Halls and open galleries, ſupported by pillars, and paved with large flag-ſtones, have been erected here on piles, for the convenience of thoſe who are fond of walking; cauſeways, caſed with cut ſtone, traverſe the lake in different directions; and the openings which are left in them at intervals, for the paſſage of boats, are covered by handſome bridges. In the middle of the lake are two iſlands, to which company reſort, after having amuſed themſelves with rowing; and on theſe a temple and ſeveral pleaſure-houſes have been conſtructed for their accommodation. The emperor has a ſmall palace in the neighbourhood. The Engliſh ambaſſador viſited this place in November, 1793: 600 miles E.S.E. of Pe-king. N. lat. 30° 20′. E. long. 119° 46′.

HANGWITE, Hangwita, a mulct impoſed for the hanging a thief, or felon, without courſe of law; or even for ſuffering him to eſcape out of legal cuſtody.

The word is alſo written, corruptly, *hangwith*, or *hankwite*. It is formed from the Saxon *hangian*, *to hang*, and *wite*, *mulct*, *compenſation*.

Hangwite, *to be quit of*, *quietus eſſe de hangwita*, in *Royal Charters*, denotes an immunity or freedom from the mulct or penalty above mentioned. "Quit de larron pendu ſans ferjeants le roy."

HANHIKIVI, in *Geography*, a ſmall iſland on the E. part of the gulf of Bothnia. N. lat. 64° 13′. E. long. 24° 12′.

HANIG, in our *Old Writers*, a term for cuſtomary labour to be performed.

HANIMMET, in *Geography*, a town of Africa, in the empire of Morocco; 30 miles E. of Morocco.

HANK, a town of Egypt; 10 miles N.E. of Cairo.

Hank *for hank*, in *Sea Language*, is a phraſe uſed for two ſhips which tack and make a progreſs to windward together.

Hank, a term, provincially employed to ſignify a withe or rope for faſtening a gate, &c.

Hanks, in a *Ship*, are certain wooden rings fixed upon the ſtays of a ſhip, whereby to confine the ſtay-ſails to them at different heights. They are a later invention, and much more convenient than the grommets, and uſed inſtead of them.

HANKIUS, Martin, in *Biography*, was born at Breſlaw in 1633. He was educated partly in his native city, and partly at Jena, where he acquired a reputation which cauſed him to be invited to the profeſſorſhip of morals and hiſtory at Gotha. In 1661 he was called to a ſimilar office at Breſlaw, where he was alſo librarian, rector of the college, and inſpector of the ſchools. By many learned works Hankius extended his fame throughout Germany. He cloſed a very laborious life, in 1709, at the age of ſeventy-ſix. His principal works are, "De Romanarum Rerum Scriptoribus," two vols. 4to.; "De Byzantinarum Rerum Scriptoribus, 4to; various Tracts on the Hiſtory and Antiquities of Sileſia, &c. Moreri.

HANNA, in *Geography*, a town of Lithuania, in the palatinate of Brzeſc; 24 miles S. of Brzeſc.

HANNACHREEN, a ſmall iſland near the W. coaſt of Ireland; 6 miles E. of Rinvell point. N. lat. 53° 36′. W. long. 9° 10′.

HANNAH Bay, a bay in the S. part of James's bay, in Hudſon's bay, where the Hudſon's bay Company have a factory. N. lat. 51 12′. W. long. 80°.

Hannah's *Town*, a town of America, in Weſtmoreland, Pennſylvania; 26 miles E. of Pittſburg.

HANNAQUAW, in *Ornithology*, the name by which Bancroft diſtinguiſhes the Phaſianus parraka.

HANNAS, in *Geography*, a town of Sweden, in the province of Smaland; 90 miles N. of Calmar.

HANNEMAN, Adrian, in *Biography*, a painter, born at the Hague in 1611. He was a diſciple of Hubert Ravenſtein, but formed his taſte by ſtudying the works of Vandyke, which he frequently copied ſo ſucceſsfully, that his pictures have been taken for originals by that great maſter. He uſually imitated him in the airs of his heads and the hues of his colouring; but his compoſitions are hard, ſtiff, and ill ſet together, and ſeldom is his whole picture equally completed.

He was in England, practiſing his art, for ſixteen years, and has left many portraits in the houſes of the great. After his return to the Hague he became the favourite painter of the

the princeſs Mary of Orange, ſometimes employing himſelf upon ſubjects of an hiſtorical and allegorical nature. Of the latter kind is a large picture in the hall formerly of the States of Holland, repreſenting peace by the figure of a beautiful woman ſeated on a throne, holding a dove on her knees, and crowned with wreaths of laurel by two genii. The compoſition is rich, is highly laboured, and painted with great clearneſs and force. He died in 1680, aged 69.

HANNEMANN, John Lewis, a phyſician, was born at Amſterdam. Having relinquiſhed the ſtudy of theology, he turned his attention to medicine, took his firſt degrees in that ſcience, and practiſed the profeſſion in ſeveral parts of Germany. When ſettled at Hamburgh, in 1675, he was invited to a profeſſorſhip in the univerſity of Kiel, in Holſtein. In the ſame year he received the degree of doctor at Copenhagen, and from that time continued to fulfil the duties of his profeſſorſhip at Kiel during a period of about 50 years. In the year 1680 he was elected a member of the Acad. Naturæ Curioſorum, under the appellation of Neſtor II. which ancient perſonage he appears to have reſembled in ſtrength of conſtitution; for he entered into a ſecond marriage in 1718, when at the age of 78. He died on his birth day, the 25th of October 1724, at the age of 84, and bequeathed his library to the univerſity. His prejudices in favour of the ancients were ſo deeply rooted, that he ſet up an obſtinate oppoſition to the doctrine of the circulation of the blood. His writings, which were not few, abound with other inſtances of prejudice and defective judgment, which render them of little value at preſent. Eloy Dict. Hiſt.

HANNIBAL, ſon of Hamilcar, a famous Carthaginian general, was, as we have ſeen (ſee Hamilcar), educated in his father's camp, and inured from early life to all the labours of the field. When he was only nine years old, he attended his father into Spain, and, though ſo young, fervently took a ſolemn oath never to be at peace with the Romans. After the death of Hamilcar he was appointed to the command of the cavalry in Spain; and, upon the death of Aſdrubal, he was entruſted with the ſole command of all the armies of Carthage, though at that time not 25 years of age. During the next three years his ſucceſs was ſo great that he ſubdued all the nations of Spain which oppoſed the Carthaginian power, and took Saguntum after a ſiege of eight months. This city was in alliance with the Romans, and its fall was the cauſe of the ſecond Punic war, which Hannibal prepared to ſupport with all the courage and prudence of a conſummate general. He levied three large armies, one of which he ſent to Africa, a ſecond he left in Spain, and he marched at the head of the third towards Italy. He came to the Alps, which had till this moment been regarded as inacceſſible, and had never been paſſed, as it was believed, but by Hercules. After much trouble, however, and almoſt inceſſant exertion, he gained the ſummit in about nine days; and had made the path ſo clear, that his elephants and heavy baggage was eaſily tranſported acroſs theſe immenſe mountains, but it was with the amazing loſs of nearly thirty thouſand men. Conquerors are not apt to calculate, or even regard the coſts of an expedition. It is ſufficient for them that it ſucceeds; and the deſtruction of their men gives them little or no concern. As Hannibal advanced into the country, he was met by Scipio; an engagement enſued, the Romans were defeated, and the conſul wounded. The Carthaginians next croſſed the Po, when the Roman army, being reinforced by the arrival of a large body of men under the conſul Sempronius, a general engagement was brought on, which terminated in the compiete victory of the Carthaginians. This ſucceſs, and the deep policy of Hannibal, drew over to his party many of the Ciſalpine nations, from whom he obtained vaſt aſſiſtance in numerous bodies of well diſciplined men. He is ſaid, however, to have placed ſo little confidence in their attachment, that he rarely appeared twice in the ſame dreſs, in order that he might avoid any attempt that might be made on his life. He now croſſed the Apennines, invaded Etruria; and having defeated the conſul Flaminius, he met the two conſuls, Terentius and Emilius, at Cannæ, when that engagement enſued which has been ſo long celebrated on the page of hiſtory. In this conteſt the ſlaughter was ſo great, that no leſs than 40,000 Romans were killed; and, as an evidence of the greatneſs of the victory, Hannibal ſent to Carthage three buſhels of gold rings that had been taken from nearly 6000 Roman knights ſlain in battle. It ſeemed now that nothing remained to prevent him from putting an end to the republic. He was urged with the moſt preſſing entreaties to march immediately to the gates of Rome; and he has been reproached with not knowing how to make uſe of the victory which he had ſo gloriouſly achieved. This cenſure, perhaps, did not apply to Hannibal, inaſmuch as it is ſcarcely poſſible to conceive that after ſo hard a fought battle his own army were in a condition to march to another attack, and againſt troops that had not been in action, but were waiting as a reſerve againſt any emergency. The immediate conſequence of this victory was the defection of moſt of the Roman allies in that part of Italy, and the ſurrender of the opulent city of Capua, to which the Carthaginian army advanced; and here the conquerors ſoon forgot their warlike habits in the pleaſures and riot of a luxurious city. From this circumſtance it has with much propriety been ſaid that Capua was a Cannæ to Hannibal. After the battle the Romans became more cautious; and when the dictator, Fabius Maximus, had defied the artifice as well as the valour of Hannibal, they began to anticipate better times. Marcellus, who ſucceeded Fabius in the field, firſt taught his countrymen that Hannibal was not invincible. At the ſuggeſtion of Scipio it was determined that war ſhould be carried into Africa, in order to withdraw Hannibal from Rome. When Carthage ſaw the enemy on her coaſts ſhe recalled her general from Italy, who is ſaid to have obeyed the ſummons with the moſt poignant regret. With tears in his eyes he left a country, which, for 16 years, he had kept in continual alarm, and which he began to conſider almoſt as his own property. He and Scipio met near Carthage. A general engagement enſued; the field of conteſt and of carnage was near Zama. Victory declared in favour of the Romans, and it was reported that 20,000 Carthaginians were killed on the ſpot, and an equal number made priſoners. Hannibal, unuſed to defeat, fled to Adrumetum; and now the Romans, in their turn, granted peace only on very hard terms. His credit was not deſtroyed among his countrymen by the calamitous iſſue of this battle. He was employed in ſome other military expeditions, till the Roman ſenate, refuſing to reſtore their hoſtages while Hannibal was ſuffered to be at the head of an army, he was neceſſarily deprived of his command. The office of pretor was now conferred upon him; and in executing it he diſplayed talents that rendered him great as a ſtateſman as he had been illuſtrious as a general. He regulated the finances, rectified abuſes in the adminiſtration of juſtice, and expoſed various frauds and corruptions in the public officers. He was too honeſt for the purlieus of a court, and was obliged to withdraw from his country. At Tyre he was received with all the diſtinction due to his character. From thence he paſſed by Antioch to Epheſus, where Antiochus then was, with whom he had many conferences concerning his meditated war with the Romans. He adviſed that Italy

ſhould be made the ſeat of war; and he offered, if placed at the head of a ſufficient body of troops, to make a deſcent on that country, and keep the enemy engaged till Antiochus ſhould arrive with the main force. The Carthaginians became jealous of the talents and exertions of him, whom, on account of his integrity, they had driven from their country. They apprized their inveterate enemies, the Romans, of what was going on, in order that they might counteract his influence. Through the artifices of the Romans, Antiochus began to be ſuſpicious of the fidelity of the veteran commander; and though there was no reaſon for the jealouſy, the monarch was baſe enough to meditate a deſign of delivering him up into the hands of his enemies. Hannibal was apprized of the fact in time to prevent the treachery; and he fled to Pruſias, king of Bithynia. Him he endeavoured to excite againſt the Romans, thus in every inſtance proving that he was not regardleſs of the oaths he had taken in his childiſh years. Roman vengeance followed him to Bithynia, and an embaſſy was ſent to demand of Pruſias inſtantly to give up Hannibal. When he found there were now no means of eſcape, and that Pruſias had actually ſurrounded his houſe with a troop of ſoldiers, he ſwallowed a poiſon which he had always ready againſt ſuch an emergency, and died in the year B.C. 183, at the age of 63. With his laſt breath he is ſaid to have exclaimed: "Solvamus diuturnâ curâ populum Romanum, quando mortem ſenis expectare longum cenſet." Univ. Hiſt. Corn. Nepos.

HANNIBAL, in *Geography*, a military townſhip in New York, on lake Ontario; 10 miles S. by W. of Fort Oſwego.

HANNO, in *Biography*, a Carthaginian commander, celebrated for his voyage of diſcovery, is ſaid to have undertaken the circumnavigation of Africa, by order of the ſtate, which he completed from the ſtraits of Gibraltar, to the extremity of Arabia. He drew up an account of his voyage in the Punic language, which, though not entitled to much credit, was tranſlated into the Greek language. A ſhort work, under the name of the "Periplus of Hanno" is extant, and was firſt publiſhed by Froben, in 1533. It was reprinted in Hudſon's "Geographiæ Veteris Scriptores Græci minores," in 1698. Its authenticity is much doubted, and it has been aſcribed to ſome Greek in Sicily. Bayle. Moreri.

HANNOYS, in *Geography*, a ſmall iſland in the Engliſh channel, about half a mile from the W. coaſt of the iſland of Guernſey.

HANOVER, the chief city of the Hanoverian dominions, is ſituated in the principality of Calenberg, among numerous gardens and villas, on the river Leine, which divides it into the Old and New Towns. Hanover, or Alſtadt Hanover, lies on the left ſide of the Leine, which, running in two channels between the old and new towns, and thus forming an iſland, unites into one ſtream again, and then becomes navigable. The town is fortified, and contains about 1200 houſes, among which are ſeveral large and handſome buildings. The elector's palace fronting the Leine, having been deſtroyed by fire, was rebuilt with great magnificence in 1741. This was the ſeat of the privy-council, of the regency, and of the commiſſioners of war. In a ſplendid chapel, belonging to this palace, was kept a treaſure highly valued, conſiſting of relics, gold and ſilver plate, and gems collected by duke Henry the Lion, in his journey to the Eaſt in 1171, and the ſucceeding years, which was firſt lodged at Brunſwick, and from thence brought to Hanover. The ſtate-houſe is a grand ſtructure. Hanover contains three pariſh churches, a poor-houſe, and three hoſpitals. In this town are manufactures of lace, ſtuff, ſtockings, ribbons, &c.; the tanneries form a conſiderable branch of trade, and alſo a kind of white beer, invented in 1526 by one Brochar, whoſe name it bears. Hanover was unknown before the year 1163.

The Neuſtadt Hanover is ſituated on the right ſide of the Leine, oppoſite to Old Hanover, and communicates with it by means of bridges. This town is fortified, and though it contains hardly 400 houſes, is well built and populous. The civil juriſdiction is veſted ſolely in its magiſtracy. It contains ſeveral valuable manufactures; and a library particularly rich in books of hiſtory and politics; 58 miles S.E. of Bremen. N. lat. 52° 23'. E. long. 9° 43'.

HANOVER, *Electorate of*, called alſo the electorate of Brunſwick Luneburg, a ſtate of Germany on the N. of the Mayn, containing about 8224 ſquare miles, with 850,000 inhabitants, and the computed revenue of 962,500*l.* ſterling, and a military force eſtimated at 20,000, or, by Hoeck computed at 25,970 perſons. This electorate is ſituated in the circle of Lower Saxony, and compriſes the duchy of Lunenberg, Bremen, and Verden, and Saxe-Lauenburg adjacent to Holſtein on the northern ſide of the Elbe; with the countries of Calenberg and Grubenhagen in the ſouth, and thoſe of Diepholtz and Hoya in the weſt, and that of Dunneberg in the eaſt. The compact part of the Hanoverian dominions extends in length, E. to W. about 180 miles, and in breadth N. to S. about 100 miles; while the detached duchy of Grubenhagen, with ſouthern Calenberg or the country of Gottingen, is about 80 miles in length by 30 in its greateſt breadth. The electors of Hanover ſpring from the ancient dukes of Brunſwick. Erneſt died in 1698, having married Sophia daughter of Elizabeth, daughter of James I. of England. He was ſucceeded by his ſon George Lewis, elector, in 1698, who became king of England in 1714.

The religion of this electorate is Lutheran; it contains about 750 pariſh churches, with ſeven ſuperintendants. The government was, before the conqueſts of the French, conducted by a council of regency, and there were provincial ſtates, though ſeldom ſummoned. The literature of this country has deſerved conſiderable applauſe ſince the inſtitution of the univerſity of Gottingen by George II. (See GOTTINGEN.) The manufactures and commerce of this electorate are pretty conſiderable, in metals from the Hartz, linen, cotton, ſome broad cloths, &c. The ſilver fabrics of Zell are celebrated in Germany. The chief exports are metals, coarſe linens, timber, peat, with ſome cattle and grain. The aſpect of the country is plain, partaking ſomewhat of the ſandy nature of Braudenburg, except in the ſouth, where riſe the lofty and pictureſque mountains of the Hartz. The agricultural products are wheat, rye, barley, oats, peas, haricots, and pot-herbs of all kinds, with abundance of potatoes, good fruits, flax, hemp, tobacco, madder, &c. Wood abounds both for fuel and building, and affords conſiderable quantities of tar and pitch. Bees are particularly regarded. Horſes, cattle, and ſheep are numerous; and game is not rare. The chief rivers are the Elbe, towards the north, the Weſer and the Leine on the weſt, and the Aller and Ilmenau in the centre. It has a few ſmall lakes, ſuch are thoſe of Diepholtz and Stinhuder. The Hanoverian dominions contain many ſmall foreſts, and woods, beſides thoſe of the *Hartz*; which ſee. The mineralogy is rich, conſiſting of ſilver, copper, lead, iron, cobalt, and zinc; with marble, ſlate, coal, turf and limeſtone. Two curious mineral ſubſtances, boracite and ſtaurolite, are found, the former in the Kalkberg, the latter at Andreaſberg in the Hartz. In October 1801 Hanover, was taken

taken poſſeſſion of by the king of Pruſſia, but evacuated in November. In 1803 it was invaded by the French.

HANOVER, a bay in the ſea of Honduras, on the E. ſide of the peninſula of Yucatan, from which it receives the waters of the Rio Honde. N. lat. 18° 45'. W. long. 89° 15'.—Alſo, a townſhip in Luzerne county, Pennſylvania.—Alſo, a townſhip in Waſhington county.—Alſo, *Eaſt* and *Weſt Hanover*, two townſhips in Dauphine county in the ſame ſtate.—Alſo, a poſt-town, called "M'Alliſter's town," in York county, Pennſylvania, containing about 160 dwellings, a German Lutheran, and a German Calviniſt church; 18 miles S.W. of York.—Alſo, a poſt-town in Plymouth county, Maſſachuſetts, 25 miles S.E. of Boſton; incorporated in 1727, and containing 958 inhabitants.—Alſo, a poſt-town of New Hampſhire, on the E. ſide of Connecticut river, in Grafton county. Dartmouth college in this town is ſituated on a plain in N. lat. 43° 43'. W. long. 72° 14'; for an account of which, ſee COLLEGE.—Alſo, a townſhip in Morris county, New Jerſey, 16 miles N.W. of Elizabeth town; in which is a ridge of hills, 40 miles from the ſea, having a number of mills, which ebb and flow about ſix feet twice in every 24 hours.—Alſo, a county of Virginia, lying between Pamunky and Chickahominy rivers, 48 miles long, and 22 broad, containing 6211 free inhabitants, and 8192 ſlaves.—Alſo, a ſmall poſt-town of Virginia, in the laſt-mentioned county, on the W. ſide of the Pamunky; 110 miles N.N.W. of Waſhington city.

HANOVER, *New*, the weſtern part of North America, bordering on the coaſt of the North Pacific ocean, ſituated between New Cornwall, and New Georgia, ſo called by capt. Vancouver, who explored the coaſt in 1792 and 1793; extending from N. lat. 45° 30' to 53° 15'.

HANOVER, *New*, a fine large iſland in the Pacific ocean, ſo called by Capt. Carteret in 1767, about 30 miles in length. Between this iſland and New Ireland there is a ſtrait or paſſage, which turns away to the N.E.; in which paſſage are ſeveral ſmall iſlands, upon one of which there is a remarkable peak: this iſland was called "Byron's iſland," and the paſſage, or ſtrait, was called "Byron's ſtrait." The land of New Hanover is high; it is finely covered with trees, among which are many plantations, and the whole has a moſt beautiful appearance. The S.W. point, called "Queen Charlotte's foreland," lies in S. lat. 2° 29'. E. long. 148° 27'.

HANSBACH, or HANSPACH, a town of Bohemia, in the circle of Leitmeritz, in which are manufactures of cotton, thread, and paper; 12 miles N. of Kamnitz.

HANSE, or HANS, an ancient name for a ſociety or company of merchants; particularly that of certain cities in Germany, &c. hence called *hanſ-towns*.

The word *hanſe* is obſolete High Dutch, or Teutonic; and ſignifies, as Lambecius obſerves in his "Origines Hamburgenſes," *alliance*, *confederacy*, *aſſociation*, &c. In this ſenſe it is uſed in two of king John's charters, in 1199, to Dunwich in Norfolk, and the city of York. Some, as Werdenhagen, who has been followed by many later authors, derive it from the three German words, *an-der-ſee*, that is, *on the ſea*; becauſe the firſt *hanſe towns* were all ſituate on the ſea-coaſt; whence the ſociety is ſaid to have been firſt called *an-der-ſee ſteten*, that is, *cities on the ſea*; and afterwards, by abbreviation, *hanſee*, and *hanſe*.

HANSE *Towns* denote certain free towns of Germany, and the North, united in ſtrict league, under laws and magiſtrates of their own appointing, for the better carrying on of commerce, and for their mutual ſafety and aſſiſtance.

This celebrated aſſociation, which makes ſo great a figure in the hiſtory of commerce, is ſuppoſed by Werdenhagen to have commenced in the year 1169, immediately after the incurſions and piracies of the Danes, &c. The learned Lambecius is of opinion, that it did not properly commence till after the league between Lubeck and Hamburgh, in the year 1241; Thuanus, in lib. li. Hiſt. Sui Temp. traces the origin of it to the year 1200; others trace its firſt riſe to the year 1140; but be its origin when it will, it was confirmed and re-eſtabliſhed in 1226 and 1284; and an extraordinary general aſſembly was held every ten years, at which they ſolemnly renewed their league, admitted new members, and excluded old ones, if they were refractory, &c.

It began with a league of mutual defence between the cities of Lubeck and Hamburgh, which were moſt expoſed to the piratical incurſions of the barbarous nations that ſurrounded the Baltic, and it afterwards conſiſted of twelve towns, ſituate on the coaſts of the Baltic ſea, or not far from it. But its ſtrength and reputation increaſing, there was ſcarcely any trading city in Europe that did not deſire to be admitted into it. However, it ſeems to have been a ſtanding rule of this confederacy, that no city ſhould be admitted into the *hanſe* or *hanſeatic* league, but ſuch as were either ſituated on the ſea, or on ſome navigable river, commodious for maritime commerce.

The moſt conſiderable cities ſcattered through thoſe vaſt countries which ſtretch from the bottom of the Baltic to Cologne on the Rhine, joined in this famous league, which, in proceſs of time, became ſo formidable, that its alliance was courted, and its enmity was dreaded by the greateſt monarchs. The members of this powerful aſſociation formed the firſt ſyſtematic plan of commerce known in the middle ages, and conducted it by common laws enacted in their general aſſemblies. They ſupplied the reſt of Europe with naval ſtores, and pitched on different towns, the moſt eminent of which was Bruges in Flanders, where they eſtabliſhed ſtaples, in which their commerce was regularly carried on. Thither the Lombards brought the productions of India, together with the manufactures of Italy, and exchanged them for the more bulky, but not leſs uſeful, commodities of the North. The hanſeatic merchants diſpoſed of the cargoes which they received from the Lombards in the ports of the Baltic, or carried them up the great rivers into the interior parts of Germany.

Under our king Henry III. who, in the year 1266, made a conſiderable grant of immunities to the hanſe towns, the hanſe conſiſted of no leſs than ſeventy-two cities; to which were afterwards added ſeveral more. France furniſhed to the confederacy Calais, Rouen, St. Malo, Bourdeaux, Bayonne, and Marſeilles; Spain, Barcelona, Seville, and Cadiz; England, London; Portugal, Liſbon; the Low Countries, Antwerp, Bruges, Rotterdam, Oſtend, and Dunkirk; and Italy and Sicily, Meſſina, Leghorn, and Naples. However, the number of the hanſe towns, which were probably members of the hanſeatic league, and contributed to its ſupport, was ſixty-four, in the year 1370, which was the period when this mercantile confederacy was in its zenith of power and glory; moſt of which have long ſince deſerted the league; ſome about the year 1512, and ſome afterwards. Beſides theſe there were forty-four towns that were probably allies of the confederacy, and were exempted from annual contributions, and to theſe ſeveral others, ſuch as thoſe above-mentioned, were added.

As the members of the hanſe aſſociation exerciſed a juriſdiction among themſelves, they were divided into four claſſes,

claſſes, colleges, or provinces, diſtinguiſhed by the names of their four principal cities, which were thoſe of Lubeck, Cologn, Brunſwick, and Pruſſia or Dantzick. Theſe four cities were the heads of the four claſſes, in which were held their courts of judicature; and Lubeck was the head of the whole hanſe.

Beſides this, the hanſe had four principal factories, or ſtaples, called the *comptoirs* of the confederacy: theſe were at London, Bruges, Novgorod, and Bergen; that of Bruges was afterwards removed to Antwerp. But the firſt and principal was that of Lubeck, which long remained the head of the aſſociation. That of London was called *Guildhalla Teutonicorum*, or the *Steel-yard*; which ſee. The factory in London was complained of by the Engliſh merchants in 1551, for having ingroſſed the woollen cloth trade, ſo that it had exported 50,000 pieces, while all the Engliſh together had ſhipped off only 1100 pieces. And, therefore, in the following year, in the reign of Edward VI. the privileges this company had obtained were revoked. Queen Mary, who aſcended the throne in the next year, ſuſpended the execution of the act for three years; but after that term, either by reaſon of ſome new ſtatute, or in purſuance of that of king Edward, the privileges of the company were no longer regarded, and all efforts of the hanſe towns to recover this loſs were ineffectual. In the beginning of Elizabeth's reign, the merchants of the hanſe towns made loud complaints; to which ſhe prudently replied, that ſhe would ſtill protect them in the privileges and immunities of which ſhe found them poſſeſſed; with this anſwer they were not ſatisfied; and their commerce was ſoon after ſuſpended for a time, to the great advantage of the Engliſh merchants, who took the whole trade into their own hands, and, encouraged by ſucceſs, divided themſelves into ſtaplers and merchant adventurers; the former reſiding conſtantly at one place, and the latter trying their fortunes in other towns and ſtates abroad with cloth and other manufactures. This ſucceſs ſo enraged the hanſe towns, that they attempted, by every method which they could deviſe, to draw upon the Engliſh merchants the ill opinion of other nations and ſtates. They prevailed ſo far as to obtain an imperial edict, by which the Engliſh were prohibited all commerce in the empire. The queen, by way of retaliation, retained 60 of their ſhips, which had been ſeized in the river Tagus with contraband goods of the Spaniards. Theſe ſhips the queen intended to have reſtored, as deſiring to have compromiſed all differences with thoſe trading cities; but when ſhe was informed that a general aſſembly was held at Lubeck, in order to concert meaſures for diſtreſſing the Engliſh trade, ſhe cauſed the ſhips and cargoes to be confiſcated; and the hanſe ſtates were informed, that ſhe had the greateſt contempt imaginable for all their proceedings.

The government of the hanſe was at firſt ariſtocratical: then it came under the ſole direction of the grand-maſter of the Teutonic order; and, at length, divers princes and lords made intereſt for it.

The end of the fourteenth century, and the beginning of the fifteenth, were the moſt flouriſhing times of this alliance. Theſe towns were then in a condition to proclaim war againſt kings: hiſtory is not ſilent as to that they waged againſt Waldemar III. king of Denmark, about the year 1348, when they took ſuch revenge of the Daniſh fleet in the Sound, for having interrupted their commerce, that Waldemar, for the ſake of peace, gave up the whole of Schonen for 16 years, in conſequence of which they commanded the paſſage of the Sound in their own right. In 1428 they made war againſt Eric, king of Denmark, in which was the hanſeatic fleet, conſiſting of two hundred and fifty ſhips, containing about twelve thouſand regular troops, beſides the ſeamen; who ſacked and plundered the coaſt of Jutland, &c. and obliged him to make peace with them. This ſingular republic, deſtitute of any territory, not only waged war againſt Denmark, but placed Albert of Mecklenburg on the throne of Sweden. Norway alſo fell into the vileſt ſubjection, and Bergen may be ſaid to have been garriſoned by the hanſeatic league. Many privileges were granted and confirmed to them by the kings Lewis XI. Charles VIII. Lewis XII. and Francis I. of France, as well as by the emperor Charles V. and other ſovereigns. At length, however, the ſeveral princes, whoſe principal cities were entered into the aſſociation, began to think it policy to put ſome bounds to the power, which, in time, might have proved formidable to themſelves. The means were eaſy and ſhort: each withdrew the merchants of his country from the aſſociation: by which in a little time, from the great number of cities it had comprehended, the aſſociation found itſelf ſunk to thoſe few which had begun the confederacy; which henceforth was called the *Teutonic hanſe*: though theſe continued to be ſo conſiderable in point of commerce, that they were admitted to make treaties with the greateſt kings.

The diviſions that prevailed among them contributed greatly to their fall: nor muſt it be forgotten, that the eſtabliſhment of the republic, and commerce of Holland, had its ſhare in reducing their importance.

The four cities which formed the league, were Lubeck, Cologn, Brunſwick, and Dantzick, which were called *mother towns*; as thoſe afterwards added to them were called *daughters*.

A great number of towns in Germany retained the title of *hanſe* towns; but this was rather an empty title which they affected, than any argument of their continuing to trade under the laws and protection of the ancient alliance; there being ſcarce any but Lubeck, Hamburgh, Bremen, Roſtock, Brunſwick, and Cologn, that were truly *hanſeatic*, and that had deputies at the aſſemblies held on the common occaſions of the league.

The great trade the Dutch maintained with the hanſe towns, contributed not a little towards maintaining ſome part of them in their ancient reputation; and it was principally to their alliance with that flouriſhing republic, that they owed the preſervation of their liberties; the ſuccours which ſome of them had received from the Dutch having ſaved them more than once from the enterprizes of the neighbouring princes.

However, at the end of the 16th century, the rupture with England, and alſo the independence of Holland, both already noticed, were highly injurious to this league; and in 1630, when a general aſſembly was ſummoned to Lubeck, none of the hanſeatic towns ſent deputies except to notify their dereliction. Such was the fall of this unexampled confederacy, which had often abuſed its advantages, and repaid favour with inſult; but which greatly contributed to the diffuſion of commerce and the arts of civilization, boaſted an opulence ſuperior to that of monarchs, and imparted the firſt tincture of wealth and eaſe to the north of Europe, though its effects (ſays Pinkerton) have ſtrangely eſcaped the notice of moſt hiſtorians. At preſent the hanſeatic league compriſes only three cities, Lubeck, Hamburg, and Bremen; and in the definitive treaty of indemnities, 25th February, 1803, they are acknowledged as hanſeatic cities, with

with the guarantee of their jurisdiction, and perpetual neutrality.

We refer for further particulars, to vol. i. of the "Chron. Deduction" of Anderson, who has mentioned the chief facts with respect to the commercial progress of the hanse towns, the extent of the privileges which they obtained in different countries, their successful wars with several monarchs, as well as the spirit and zeal with which they contended for those liberties and rights without which it is impossible to carry on commerce with advantage.

HANSEATIC, something belonging to the alliance, or company of the hanse.

Thus we say, the hanseatic body; the hanseatic towns, &c.

HANSGRAVE, the title of an officer in Germany. The hansgrave is the chief of a company or society.

The word is compounded of the German *hanse* and *graf*, *count*. See GRAVE.

HANSHAGEN, in *Geography*, a town of Prussia, in Natangen; 10 miles N.N.W. of Heilsberg.

HANSOOTE, a town of Hindoostan, in Guzerat; 15 miles S.W. of Baroach.

HANTAM, one of the transmontane divisions of Stellenbosch, in Southern Africa, is a Table mountain, rising from the surface of the Bokkeveld mountain, on its eastern extremity, and is surrounded by a number of farms that receive a supply of water from rills issuing out of the base of the mountain. Horses and cattle are the produce of the Hantam. The inhabitants of this division are liable to the depredation of the Bosjesmans Hottentots, against whom they make regular expeditions, in the same manner as from the Sneuwberg.

HAN-TCHAO, a small island in the Chinese sea, near the coast of Cochin-china, at the entrance of the harbour of Turon. N. lat. 16° 12'. E. long. 108° 12'.

HAN-TCHEOU, a town of Corea, in the province of Hoang-hai, on the river Tchou-nang; 140 miles N.N.W. of Kin-kitchao. N. lat. 39° 38'. E. long. 125° 31'.

HAN-TCHONG-FOU, a large and populous city of China, in the province of Chen-si, situated on the river Han, which waters the whole country belonging to its district. It has under its jurisdiction 16 cities, of the second and third class. The adjacent country is fertile, and abounding with mountains and forests. The principal articles of commerce are honey, wax, musk, and cinnabar. The most remarkable thing in this country is the high-way, cut across the mountains, which conducts to the capital. It was made by an army, in the course of a military expedition. In the execution of it, mountains were levelled, and bridges constructed which reach from one to another; and when the interposing valleys appeared too wide, large pillars were erected to support them. N. lat. 32° 59'. E. long. 106° 44'.

HANTELODE, in our *Old Writers*, signifies an arrest.

The word is Saxon, from *hant*, *hand*, and *load*, *i. e. laid*; *manus immissio*, because arrests are made by laying hold on the debtor, &c.

HANTOL, in *Botany*, a tree of the Philippine islands, whose fruit is called the false mangostan, rather from its appearance (though it has neither a calyx at the base, nor a radiated stigma at the summit, like the true one, see GARCINIA), than from any agreement in flavour. It has indeed a slight acid taste, which is said not to be disagreeable at first, but leaves a flavour of garlic. This fruit serves chiefly to make a syrup, jelly, or other sweetmeat for the table. Lamarck. Dict. v. 3. 69. See SANDORICUM.

HANTON-HOTUN, in *Geography*, a town of Chinese Tartary; 17 miles N.W. of Nimgouta.

HANTS, a county of Nova Scotia, beginning about 30 miles from Halifax, and containing the townships of Windsor, Falmouth, and Newport, with several unsettled tracts. It is about 20 miles square, and well watered. It is intersected by several navigable rivers.

HANWAY, JONAS, in *Biography*, was born at Portsmouth in the year 1712; at an early age he was put apprentice to a merchant at Lisbon, where he acquired the Portuguese language. In 1743, he entered partnership with the English house of Dingley, at Petersburgh, and the mercantile transactions of that house brought him acquainted with the trade lately commenced on the Caspian sea. The concerns of the partnership obliged one of the firm to be constantly in Persia. Mr. Hanway gladly seized the opportunity of visiting that country, and arrived at Astrabad in the latter part of that year, with a cargo of English goods. In this expedition his health was materially injured, but he was enabled to obtain a knowledge of the manners, the customs, and modern history of Persia, which few Europeans ever before possessed. Upon his return he published, in four volumes 4to., his "Historical Account of the British Trade over the Caspian Sea; with a Journal of Travels from London, through Russia, Persia," &c. This work abounds with curious and instructive matter, but is too prolix to be read with real satisfaction. From this time, Mr. Hanway was frequently before the public as an author: all his publications related to some point of public good, in promoting schemes of charity and utility, or in proposing means of bettering the condition, and mending the morals of the lower classes of society. He was the principal founder of the Marine Society, intended to train young and destitute lads to the service of the navy; he was particularly active in the success of the Magdalen charity, which it is hoped has been of vast advantage to a number of the most pitiable objects in the city of London, in withdrawing them from the paths of prostitution, and rendering them useful members of the community. The institution of Sunday-schools is almost wholly the work of Mr. Hanway; and the forlorn climbing-boys, frequently sold by base and infamous parents, to the service of more cruel masters, claimed a large portion of his humane interference. His fellow-citizens thought so highly of his active worth, that a deputation of British merchants waited on the minister lord Bute, with a request that some public favour might be conferred on a man, who had done so much service to the community, at the expence of his private fortune. Mr. Hanway was, in consequence, made a commissioner of the navy, an office which he held about 20 years, when he resigned it; the salary was, however, continued to him through life. He died in the year 1786, and a monument was raised to his memory by subscription. The best and most important memorial he erected to his own fame, in a little work intended for the lower classes upon their entrance into life: it is entitled "Advice from Farmer Trueman to his Daughter Mary, upon her going to service," &c. One of the editors of this work, a lady of distinguished literary attainments, has observed that "Mr. Hanway has written professedly for the poor, and his memory will live and be respected in the character of Farmer Trueman, long after the period when all worldly distinctions will have ceased to be of any value." See the work printed for Johnson & Co. See also Gen. Biog. and Monthly Review, vol. xliii.

HANWAY'S *Point*, in *Geography*, a cape on the N. coast of Egmont island. S. lat. 10° 42'. E. long. 164° 22'.

HANXLET, a small island in the eastern part of the gulf of Bothnia. N. lat. 63° 19'. E. long. 21° 30'.

HAN-YANG-FOU, a city of China, of the first rank, in

the province of Hou-quang, at the conflux of the rivers Han and Yan-tfe: it is rich, populous, and commercial. N. lat. 30° 36'. E long. 113° 44'.

HAO, a *weight* ufed in China, the one 10,coodths of their foot, = $\frac{1}{10000}$ li, = $\frac{1}{1000}$ fen, = $\frac{1}{10}$ inch of China. See Philofophical Magazine, vol. 36, p. 428.

HAP, or HAPP, in *Law*, fignifies to catch or fnatch a thing. Thus we meet with, to *hap* the poffeffion of a deed-poll. Littleton, fol. 8. alfo, to *hap* the rent. If partition be made between two parceners, and more land be allowed the one than the other, fhe that hath moft of the land charges it to the other, that *happeth* the rent whereon affize is brought.

HAP, in *Agriculture*, a term provincially ufed to fignify the covering of feed with mould or earth.

HAPAEE, in *Geography*, a cluiter of iflands among the Friendly iflands, in the South Pacific ocean, each of them about fix or feven miles long, and of a fimilar height and appearance. The northernmoft is called Haanno, the next Foa, the third Lefooga, and the fouthernmoft Hooleiva. They extend S.W. by S. and N.E. by N. about 19 miles. The N. end lies in S. lat. 19° 39', and 33' of longitude to the eaft of Annamooka. Between them are many fmall iflands, fand-banks, and reakers. Lefooga is the moft fertile, and of courfe the beft inhabited. Along the N.W. of this ifland there is anchorage. The inhabitants are very hofpitable, and fond of dancing and other amufements. They lie about S. lat. 19° 39' to 19° 53', and E. long 185° 36 to 185° 45'.

HAPAJERSIN, a town of Sweden, in Eaft Bothnia; 30 miles S.S.W. of Braheftad.

HAPALANTHUS, in *Botany*. See CALLISIA.

HAPIREAN, in *Geography*, a town of Chinefe Tartary, in the county of Hami.

HAPHREAN *Poulee*, a town of Afia, in Thibet; 25 miles W.N.W. of Orto.

HAPPINESS, in *Ethics*. See GOOD.

HAQUE, in our *Old Writers*, a little hand-gun, prohibited to be ufed for deftruction of game, &c. by ftatute 33 Hen. VIII. cap. 6. and 2 & 3 Ed. VI. cap. 14.

There is alfo the *half-haque*, or *demi-haque*, within the faid acts.

HAQUENY, HACKNEY, an old French word for an ambling horfe.

HAQUEBUT, a kind of fire-arm, otherwife called an *hagbut* or *harquebufs*.

HARA, in *Geography*, a lake of Thibet. N. lat. 36° 42'. E. long. 97° 19'.

HARA *il Coma*, a town of Little Bukharia; 15 miles N. of Acfu.

HARACH, in the *Eaftern Revenues*, is a poll-tax laid on the Chriftians and Jews in Egypt. This had long been in the hands of the Janizaries, but of late has got into the power of an officer, called thence the *harach aga*, fent from Conftantinople. Before this the Chriftians paid but a trifle, by capitulation with fultan Selim; and this capitulation the Coptis fay they have in their own hands; it was only two dollars and three quarters a head. The great men confented to this: and now they pay their two or three quarters, or five and a half, or eleven, according to their fubftance, each dollar being about half a crown. The perfons who pay this are thofe only who have arrived at the age of fixteen. Pocock's Egypt, p. 173.

HARACHER-HOTUN, in *Geography*, a town of Thibet; 160 miles W. of Tourfan. N. lat. 43° 4'. E. long. 86° 16'.

HARÆ, in *Ancient Geography*, *Tarecca*, a town of Syria in the Palmyrene, mentioned in the Theodofian table; fituated to the eaft of a chain of mountains, and almoft N. of Palmyra, towards N. lat. 34° 25'.

HARAKER, in *Geography*, a town of Sweden, in the province of Weftmanland; 12 miles N. of Weftera.

HARAM, a fmall ifland in the Red fea, near the coaft of Arabia. N. lat. 22° 18'.

HARAM. See HAREM and SERAGLIO.

HARAMFOE, in *Geography*, a fmall ifland in the North fea, near the coaft of Norway. N. lat. 62° 36'.

HARAN, otherwife CHARRÆ, in *Ancient Geography*, a city of Mefopotamia, whither Abraham firft retreated after he left Ur; and where Terah, Abraham's father, died and was buried. (Gen. xi. 31, 32.) At Haran, or Charræ, Craffus, the Roman general, was defeated and ilain by the Parthians. It was fituated between the Euphrates and the river Chebar, at a conliderable diftance from the confluence of thefe rivers.

HARANGUE, a modern French name for a fpeech, or oration, *i. e.* a difcourfe made by an orator in public.

Menage derives the word from the Italian *arenga*, which fignifies the fame: formed, according to Ferrari, from *aringo*, a *juft*, or *place of jufting*. Others derive it from the Latin *ara*, *altar*; becaufe the firft harangues were made before altars: whence the verfe of Juvenal.

"Aut Lugdunenfis rhetor dicturus ad aram."

The word is alfo frequently ufed in an ill fenfe: *viz.* for a too pompous, prolix, or unfeafonable fpeech or declamation. In Homer, the heroes generally harangue before they come to fight; as, in England, criminals harangue on the fcaffold before they die.

HARATCH, in *Geography*, a river of Africa, anciently called "Savus," which runs into the fea; 6 miles S. E. of Algiers.

HARBAGHE', a town of Nubia, on the left bank of the Nile; 63 miles N. of Sennaar. N. lat. 14° 40'. E. long. 33° 5'.

HARBINGER, an officer of the king's houfhold, having four yeomen under him, who ride a day's journey before the court when it travels to provide lodgings, &c.

HARBO, in *Geography*, a town of Sweden, in Weftmanland; 20 miles N. N. W. of Upfal.

HABOROUGH, or MARKET-HARBOROUGH, a market town in the hundred of Gaftre, and county of Leicefter, England, is fituated near the bank of the river Welland. It is now a refpectable well-built town, having been lately very materially improved, and feveral new houfes having been erected. Many of the buildings are, however, included in the parifhes of Great and Little Bowden; to the former of which this town is attached. In the Teftа de Nevill this place is called both Herberburr Buggedon, and Haverberg, and by the latter name it is defignated in moft other ancient writings wherein it is mentioned: haver being, as Johnfon informs us, a common word, in the northern counties, for oats. Harborough has a ftrong claim to Roman antiquity. On the eaft fide of the town are traces of an ancient encampment, which, from its form, may be conlidered of Roman origin. At a fhort diftance, both eaft and weft, Roman urns, and other pottery, have been difcovered; and even in the ftreet, an ancient drain was lately found, a few feet below the furface, which appeared to be of Roman maionry. The encampment was of a fquare form, and included about fix acres of land; the banks and fofs are nearly levelled, the moft conlpicuous remains being in an old inclofure, called the King's Head Clofe. Near this fpot, in the year 1779, were difcovered two fepulchral urns,

urns, one of a large ſize, the other ſmaller. It is rather a curious circumſtance, that Harborough has no land or fields belonging to it; whence originated the local proverb, that "A gooſe will eat all the graſs that grows in Harborough field." In eccleſiaſtical affairs, this town is dependent on the pariſh of Bowden Magna: its chief religious ſtructure being only a chapel of eaſe. This building, however, is large, handſome, and nearly uniform in its ſtyle of architecture. It may be fairly ranked with the fineſt religious edifices in the county; and conſiſts of a nave, two aiſles, a chancel, with two tiers of windows, two porches, and a tower with a ſpire. This chapel is mentioned in an eccleſiaſtical record of 1344, where it is noticed as a parcel of the rectory of Bowden Magna. Mr. Nichols ſuppoſes it to have been erected by Geffrey le Scope, "whoſe arms were repeated on the ſteeple." In this town are three meeting-houſes; for Preſbyterians, Quakers, and Methodiſts. In the principal ſtreet is a large town-hall; and near the chapel is a charity-ſchool founded by Mr. Smith. In the time of queen Elizabeth, a large manufactory of ſhoes for foreign trade was eſtabliſhed here; and at preſent the making of tammies, ſhalloons, plain and figured laſtings, &c., affords employment to many poor families in the town and its vicinity. The buſineſs in theſe articles is very conſiderable; and Mr. Nichols obſerves, that in ſome years "it is computed that 30,000*l.* has been returned in the article of tammies only." Harborough is 83 miles diſtant from London; has a weekly market on Tueſday, and two annual fairs, one held by charter, the other eſtabliſhed by cuſtom; and contained, in 1801, 330 houſes, and 1716 inhabitants.

Harborough appears to have been the head-quarters of the king's army, previous to the memorable battle of Naſeby, in Northamptonſhire, which proved ſo fatal to the royal cauſe in June 1645. Nichols's Hiſtory of Leiceſterſhire, vol. ii. part. 2. fol. 1798.

HARBOROUGH *and Stamford Canal*, is a line of inland navigation which was projected in the year 1810, and ſurveyed by Mr. Benjamin Bevan the engineer, and for which a bill is at this time before parliament (Feb. 1811); it is propoſed to commence at the head of the Welland navigation at Stamford bridge, and follow pretty cloſely the courſe of the Welland on its ſouthern ſide, until within 2½ miles of Market Harborough, where it is to croſs the Welland, and proceed weſt about two miles, to join the north-eaſtern point of the loop of the Leiceſterſhire and Northamptonſhire Union canal, in the pariſh of Great Bowden, from whence the communication by water is now open to the wharf, at the north-weſt end of Market Harborough town, or to the intended Grand Union canal at Gumley, as well as to Leiceſter, Loughborough, the Trent, and all its connecting navigations. A large reſervoir is intended, about three miles from Harborough, near the Leiceſter road, on its eaſt ſide, in Weſt Langton, and two ſmaller ones, half a mile ſouth-eaſt of Huſband's Boſworth, the feeder from which laſt will fall into the Union canal, about a mile from the head of the intended Harborough and Stamford canal, where the feeder from the other will fall alſo into the Union canal.

HARBOUR, a ſea-port, or a ſtation where ſhips may ride ſafe at anchor.

The word is chiefly applied to thoſe cloſed and ſecured with a broom, or chain, and that are furniſhed with a mole, &c. See PORT.

To HARBOUR, *verb*; popularly ſignifies to lodge, receive, or entertain; or to find a retiring place.

Among hunters, a hart is ſaid to *harbour*, when he goes to reſt; whence to *unharbour* a deer, is to diſlodge him.

HARBOUR *Iſland*, in *Geography*, one of the ſmaller Bahama iſlands, north of Eleuthera. N. lat. 25° 56'. W. long. 76° 44'—Alſo, a ſmall iſland, near the coaſt of North Carolina, in Pamlico ſound. N. lat. 34° 50'. W. long. 76° 32'.

HARBOUR, a ſmall iſland in the Engliſh channel, near the coaſt of France. N. lat. 48° 39'. W. long. 1° 59'.

HARBOUR, *Cape*, a cape of North America, on the coaſt of Maine, at the north extremity of Wells bay. N. lat. 43° 18'. W. long. 70° 24'.

HARBURG, a ſmall iſland in the Red ſea. N. lat. 16° 5'.

HARBURG, or *Hearburg*, a town of Germany, on the Wernitz; 6 miles S. E. of Nordlingen.—Alſo, a ſea-port town of Germany, in the principality of Luneburg-Zell, on the Saave, which runs through it into the Elbe. The inhabitants carry on a conſiderable trade in bleaching wax, refining ſugar, manufacturing ſtarch, ribbons, hats, and ſtockings. They alſo ſend wood for building to Holland, maſts, &c. Paſſage-boats ſail from Harburg every day with paſſengers and goods, at a fixed price; 7 miles S. of Hamburg. N. lat. 53° 28'. E. long. 9° 56'.

HARCAS, a town of Tartary, and principal reſidence of the khan of the Calmucks, on the river Ili.

HARD BODIES, in *Philoſophy*, are ſuch bodies as are abſolutely inflexible by any ſhock or colliſion whatſoever.

This is the common meaning of the term: but Huygens, by hard bodies (*corpora dura*) meant what others call perfectly elaſtic bodies; for he thus expreſſes himſelf: "Quæcunque ſit cauſa, corporibus duris, a mutuo contactu reſiliendi cum ſe invicem impinguntur: ponimus, cum corpora duo inter ſe æqualia, æquali celeritate, ex adverſo ac directe ſibi mutuo occurrunt, reſilire utrumque eadem qua advenit celeritate." Huyg. De Motu Corp. ex Percuſſ. Hypoth. 2. But this hypotheſis is conſiſtent only with perfect elaſticity, and not with the common ſuppoſition of hardneſs or inflexibility, which produces no reſilition.

The laws of motion for hard bodies are the ſame as for ſoft bodies, and theſe two ſorts of bodies might be comprized under the common name of *unelaſtic*. See COLLISION.

Some who follow Leibnitz's doctrine, concerning the meaſure of the moving force of bodies, deny the exiſtence of hard or inflexible bodies. And it is ſo far true, that no experience ever taught us, that there are any ſuch. The hardeſt bodies, to appearance, do not preſerve their figures in colliſion, ſuch bodies being only elaſtic, yielding to the ſhock, and then reſtoring themſelves. See ELASTIC.

M. Bernouilli goes ſo far as to ſay, that hardneſs, in the vulgar ſenſe, is abſolutely impoſſible, being contrary to the law of continuity. For ſuppoſing two ſuch hard bodies of equal maſſes, and with equal velocities, to meet directly, they muſt either ſtop or return after the colliſion. The firſt ſuppoſition is commonly admitted; but then it follows, that theſe bodies muſt inſtantaneouſly paſs from motion to reſt, without going through ſucceſſive diminutions of their velocities till they ſtop: but this is thought to be contrary to the fundamental laws of nature. See Bernouilli Oper. tom. iii. p. 10.

Hence this author rejects perfectly ſolid and inflexible atoms, which others think a conſequence of the impenetrability of matter. See Maupert. Mem. de l'Acad. Berlin. tom. ii. p. 284.

HARD, in *Engineery*, ſignifies a ford or paſſable place in a river, particularly in and near the Fens, where many of theſe formerly occurred, compoſed of gravel, probably brought thither for the purpoſe, and which proved very detrimental to navigation in dry ſeaſons, as well as obſtructed and augmented the floods in wet ones, until they were removed; frequent mention is made of theſe hards by Mr.

Smeaton, and other writers on the navigation and drainage of theſe diſtricts.

Hard-*coals*, in *Mining*, are ſuch as can be dug and raiſed in large lumps, and are of a free or open-burning quality; they are ſometimes called ſpire-coal, and ſtone-coal, and ſeem the lithanthrax of ſome authors. The great preference ſhewn by the dealers and conſumers of coal in the midland counties to this kind, in rejection of the ſoft or tender coals, (which is the character of by far the greater number of coal-ſeams,) unleſs of the very beſt crozling or melting quality, occaſions an inconceivable waſte to be made in the pits of all but hard coals. The Report to the Board of Agriculture on Derbyſhire, very properly calls the attention of that body, and the legiſlature, to this important ſubject.

Hard-*corn* ſignifies wheat in Suſſex and ſome other counties.

Hard *horſe*, in the *Manege*, is one that is inſenſible of whip or ſpur.

Hard-*iron*, the common name of the weed corn crowfoot, in ſome places.

Hard-*lead*, in *Mining*, is applied to the ſquare-ended pieces, or half pigs, which are made at the ſlag-hearths, or mills, attached to the cupolas or reverberatory furnaces (where ſoft lead is made,) in Derbyſhire, from the drawn ſlag of the cupolas. This hard-lead, though unfit for rolling, and ſome other purpoſes, is much eſteemed by the red-lead makers, and the ſhot-makers.

Hard-*a-lee*, in *Sea Language*, denotes the ſituation of the helm, when it is puſhed cloſe to the lee-ſide of the ſhip, either to tack or keep her head to the wind, when lying-by, or trying. It expreſſes alſo the order to put the helm in this poſition.

Hard-*a-weather*, is the order to put the helm cloſe to the weather or windward ſide of the ſhip, and it ſignifies this poſition of the helm.

HARDALES, in *Geography*, a town of Spain, in the province of Seville; 10 miles S. W. of Antequera.

HARDANGER, *Gulf of*, a bay of the North ſea, on the coaſt of Norway. N. lat. 59° 50'. E. long. 6°.

Hardanger, mountains of Norway, in the province of Bergen; 60 miles E. of Bergen.

HARDBERG, a town of Germany, in the duchy of Stiria; 52 miles S. of Vienna. N. lat. 47° 18'. E. long. 15° 46'.

HARDEN's Creek, a river of America, in Kentucky, which runs into the Ohio. N. lat. 37° 40'. E. long. 86° 56'.

HARDENBURG, a town of the duchy of Berg; 13 miles E. N. E. of Duſſeldorf.—Alſo, a town of Holland, in the department of Overyſſel, on the Vecht; 10 miles S. W. of Covorden. N. lat. 52° 37'. E. long. 6° 27'.

HARDENING, the act of communicating a greater degree of hardneſs to a body than it had before.

The hardening and tempering of iron and ſteel make a conſiderable article in the mechanical arts.

There are divers ways of effecting it: as by the hammer, quenching it when hot, in cold water; caſe-hardening, &c. See Tempering and Steel.

Hardening, *Hammer*, is moſtly uſed on iron and ſteel plates, for ſaws, ſprings, rules, &c.

Hardening, *Caſe*, which is a ſuperficial converſion of iron, into ſteel (ſee Case-*hardening*) is thus performed: take cow horn or hoof, dry it well in an oven, and beat it to powder; put as much bay-ſalt as of this powder into ſtale urine, or white-wine vinegar, and mix them well together; cover the iron, or ſteel, all over with this mixture, and wrap it up in loam, or plate-iron, ſo as the mixture touch every part of the work; then put it in the fire, and blow the coals to it, till the whole lump have a blood-red heat, but no higher; laſtly, take it out, and quench it. See Steel, under which article other proceſſes for this purpoſe are deſcribed.

Hardening *of the ſtrata*, in *Geology*, is a point on which theoriſts have been much divided: Dr. Hutton, and his commentator, Mr. Playfair, have contended, that fire or heat was neceſſary for the conſolidation of the ſtrata, after their depoſit in a ſoft or pulverulent form, in the depths of the ocean.

Mr. Kirwan ſuppoſes this hardening to have been in part chemical, and to have followed immediately their depoſition, and partly the effect of ſubſequent infiltration (Geo. Eſſays, p. 45.). While others have referred to deſiccation or drying, ſince the waters retracted, as alone ſufficient to account for the hardening of the terreſtrial ſtrata. Thoſe who attentively conſider the vaſt maſs and ſucceſſion of different ſtrata, which have been explored, below the level of, and even under the coaſts of the ocean, as at Newcaſtle, Whitehaven, Borrowſtowneſs, and in Cornwall, &c., will readily perceive, that drying, in its literal ſenſe, by expoſure to the air, as may be alleged with reſpect to the ſuperficial ſtrata of mountains, and to dry land in general, could have had no part in producing the induration or hardening of theſe ſub-marine ſtrata, and which, nevertheleſs, are found ſo exactly ſimilar to the parts of the ſame ſtrata expoſed to the air, that the inference ſeems clear, that to the chemical principles which produced the depoſition of the ſtrata, is their hardening entirely to be aſcribed.

Hardening *of Timber*. The Venetians are famous for the ſoundneſs of their ſhips, which do not rot as thoſe of other nations, but will endure much longer than the others. Tachenius tells us, that the whole ſecret of this conſiſts in the manner of their hardening their timber intended for this ſervice; and that this is done by ſinking it in water while green, and leaving it there many years. This prevents the alkali, or that ſalt which furniſhes the alkali in burning, from exhaling afterwards; and by this means the timber becomes almoſt as incorruptible as ſtone. It is evident that the exhaling of this ſalt, and the rotting of wood, have ſome very great connection with one another, ſince the more ſound any piece of timber is, the more ſalt it proportionably yields; and the wood which is rotten is found on trial to contain no ſalt at all. Tachen. Hippoc. Chym.

HARDEPSEN, in *Geography*, a town of Weſtphalia, in the principality of Calenberg, having a conſiderable manufacture of leather; 10 miles N. W. of Gottingen.

HARDER, John-James, in *Biography*, an eminent phyſician, was born at Baſle on the the 17th of September, 1656, and was educated in his native city until the year 1676, when he went to complete his ſtudies in anatomy and ſurgery, in France. On his return to Baſle, in 1678, he took the degree of M. D.: in 1685 he was admitted into the faculty, and became ſucceſſively profeſſor of philoſophy, anatomy, botany, and the theory of phyſic in the ſchools of his native city. Uniting the qualities of a man of ſcience and amiable diſpoſitions with thoſe of a ſucceſsful practitioner, he was ſo much ſought after by the German princes, that, after he had attained the age of thirty, his profeſſional occupations no longer admitted of the ſtudies of the cloſet. He was honoured with the title of count palatine by the emperor Leopold in 1694. His life was terminated in 1711, or, as ſome affirm, in 1718, by a tertian fever, and his death occaſioned univerſal regret. The works, which he left,

left, are the result of the ſtudies of his youth, and their value leads us to lament that the labours of practice deprived us of the reſearches of more mature age. He publiſhed ſix different treatiſes between the years 1671 and 1687, chiefly relating to anatomy and phyſiology. See Eloy. Dict. Hiſt.

HARDER, in *Ichthyology*. See GOBIUS *Gronovii*.

HARDERWYCK, or HARDEWICK, in *Geography*, a ſea-port town of Holland, in the ſtate of Guelderland, ſituated on the Zuyder ſea. It was taken by the French in 1795; 25 miles N. E. of Utrecht. N. lat. 52° 24'. E. long. 5 31.

HARDI, ALEXANDER, in *Biography*, who flouriſhed in France during the reigns of Henry IV. and Lewis XIII., was a moſt copious dramatic writer, and is ſaid to have produced more than 600 pieces: but his ſelect works were publiſhed in five large volumes octavo. Fertility of invention was his great quality, and he is praiſed for having adopted the true ſtyle of dramatic poetry. Before the time of Corneille, he was accounted the principal French tragedian. He died about the year 1630. Moreri.

HARDICANUTE, king of England and Denmark, is chiefly known by his bodily accompliſhments. By remaining ſo long in Denmark, he had been nearly deprived of his ſhare in the kingdom, yet he did not abandon his pretenſions, but had determined before Harold's death to recover by arms what he had loſt, either by his own negligence, or by the neceſſity of his affairs. The death of his brother gave him poſſeſſion of the crown in England, without a ſtruggle. His firſt action as king, was to cauſe the dead body of his brother to be dug up and thrown into the Thames; this brutal but impotent deed he performed a ſecond time when it had been recovered and buried by ſome fiſhermen. Hardicanute ſoon loſt the affections of the Engliſh, as well by the brutality of his conduct as by his renewing the impoſition of Danegelt, and obliging the nation to pay a great ſum of money to the fleet which brought him from Denmark. Diſcontents ran high in many places, and in Worceſter the populace roſe and put to death two of the collectors of his taxes. The king, enraged at this oppoſition, ſwore vengeance againſt the city, and ordered three of his noblemen to execute his menaces with the utmoſt rigour. They ſet fire to the place, and delivered it up to the ſoldiery to be plundered; the lives of the inhabitants they ſpared, but ſent them into a ſort of exile, till, by their interceſſions, they had appeaſed the wrath of the king, and obtained his pardon. The violent government of Hardicanute was of very ſhort duration; he died as he was joining in the celebration of the nuptials of a Daniſh lord. He had ſucceeded his father to the throne of Denmark in the year 1035; to that of England in 1035, and he died in 1041. Hume.

HARDIN, in *Geography*, a county of America, in Kentucky, containing 3597 inhabitants, of whom 310 are ſlaves.

HARDING, THOMAS, in *Biography*, a zealous Catholic divine, was born at Beckington, in Devonſhire, about the year 1512. He was educated in grammar learning at Barnſtaple and Wincheſter, and from the latter place he was ſent to New College, Oxford. He took his degrees, and was appointed fellow of his college with great applauſe. He had acquired a high reputation for his ſkill in the learned languages, and was appointed by Henry VIII. profeſſor of Hebrew to the univerſity. During the reign of Edward VI. he profeſſed himſelf a Proteſtant, and was zealous in the cauſe, but when Mary aſcended the throne, and avowed her intentions of reſtoring the popiſh religion, he ſpeedily renounced the Proteſtant faith, and for his ready conformity was rewarded with a prebend in the church of Wincheſter, and immediately after proceeded doctor of divinity at Oxford. In 1555, he was appointed treaſurer of the cathedral of Saliſbury. On the acceſſion of Elizabeth he was deprived of his treaſureſhip, and not being prepared for another change in his religious faith, he reſigned his preferments and withdrew to the Low Countries. Here he ſtood forth the defender of his principles, and was regarded as one of the ableſt advocates of the Catholic cauſe. He was author of many works, of which the titles are enumerated in Wood's Athen. Gen. Biog.

HARDION, JAMES, was born at Tours in 1686. He was chiefly educated among the Jeſuits at Paris. In 1711 he was admitted into the Academy of Inſcriptions as a pupil, in 1713, he became an aſſociate, in 1728, a penſionary, and in 1730, he was elected into the French academy. He now began a "Hiſtory of the Origin and Progreſs of Rhetoric in Greece," on which ſubject he publiſhed twelve diſſertations, when he was appointed, in 1748, to inſtruct the princeſſes of France in geography, hiſtory, &c. For their uſe he publiſhed ſeveral excellent pieces, written in a pure and unaffected ſtyle, and drawn from the moſt authentic ſources. He was appointed keeper of the royal library, and died in 1766. His principal work was an Univerſal Hiſtory, in 18 vols. 12mo.

HARDMARK, in *Geography*, a town of Norway, in the dioceſe of Chriſtianſand; 11 miles S.S.W. of Chriſtianſand.

HARDNESS, DURITIES, in *Philoſophy*, that quality in bodies whereby their parts cohere firmly together, ſo as to reſiſt the touch; or it denotes that degree of reſiſtance which bodies preſent to any power that may be applied in order to ſeparate their parts.

In this ſenſe, hardneſs coincides with what, on other occaſions, we call *firmneſs*, and ſometimes *ſolidity*; in oppoſition to *fluidity*.

More ſtrictly ſpeaking, a body is ſaid to be hard, when its parts mutually cohere, ſo as not to yield inwards, or give way to an external impulſe; and therefore are not ſubject to any motion in reſpect of each other, without breaking the body. In which ſenſe hardneſs ſtands oppoſed to ſoftneſs, where the parts do readily give way. The different degrees of the attraction both of aggregation and of coheſion between the particles of the ſame ſubſtance, or of different ſubſtances, ſeem to form the whole gradation from the moſt fluid to the moſt ſolid body, whether ſimple or compound. The ſtates intermediate between theſe extremes are expreſſed by the various names of fluid, clammy; ſoft, glutinous, tenacious, hard, brittle, rigid, &c. But as theſe names are incapable of any preciſe definitions, their meanings are commonly underſtood with conſiderable latitude. The ſtate of a given body in this reſpect is aſcertained, either by obſerving the weight or force which is required to diſunite its parts, or by comparing it with other bodies; as when it is ſaid, that a ruby is ſofter than a diamond, but harder than the hardeſt ſteel, becauſe with it you may ſcratch the ſteel but not the diamond. In the formation of ſeveral ſtony concretions; in the cryſtallization of ſalts, after having been diſſolved in water; in the cooling of certain metals after fuſion, &c. a regular arrangement of parts is generally obſerved; the particles of bodies manifeſting a tendency to join in a particular way. It has likewiſe been obſerved, that in the formation of ſtony concretions, and in ſome other proceſſes, the ſlower the operation is performed, the harder are the bodies, which reſult from theſe operations. Theſe facts have ſuggeſted a ſuppoſition that the particles of the ſame ſort of matter have an attraction towards each other with

with certain ends, and a repulſion with the oppoſite parts. Hence, when they are placed in ſuch a ſituation as may allow them to follow that natural inclination, *viz.* when they are rendered fluid by heat, or by ſolution in water, &c. then they adhere to each other with their friendly parts. Alſo, when the operation proceeds ſlowly, the particles have more time to arrange themſelves properly, and conſequently form a harder body than when the operation proceeds more expeditiouſly. (Higgins on Light.) See COHESION and ELASTIC *Bodies*.

The Peripatetics make hardneſs a ſecondary quality; as ſuppoſing it to ariſe from *dryneſs*, which is a primary one, and to be in proportion to it.

Its remote cauſes, according to them, are either heat or cold, according to the diverſity of the ſubject: heat producing dryneſs, and by that means hardneſs in clay; and cold doing the like in wax.

The Epicurean and corpuſcular philoſophers account for hardneſs, from the figure of the component parts, and their union together. Accordingly, ſome aſcribe it to the atoms, or particles of the body being hooked, and thus mutually catching and hanging upon one another: but this is directly bringing that for an anſwer, which was the queſtion. For how do theſe hooked parts cohere?

Again, the Carteſians will have the coheſion of hard bodies effected by reſt; that is, by nothing at all.

Sir Iſaac Newton ſhews, that the primary particles of all bodies, whether ſolid or fluid, are hard, perfectly hard; and are not capable of being broken or divided by any power in nature.

Theſe particles he maintains to be connected together by an attractive power; and according to the circumſtances of this attraction, the body is either hard or ſoft, or even fluid.

If the particles be ſo diſpoſed or fitted for each other, as to touch in large ſurfaces, ſuch body will be hard; and the more ſo, as thoſe ſurfaces are the larger. If, on the contrary, they only touch in ſmall ſurfaces, the body, by the weakneſs of the attraction, will remain ſoft. See COHESION.

Fluidity has been found by the experiments of ſome modern chemiſts and philoſophers, to conſiſt in the motion of the particles of a body upon one another in conſequence of the action of a fluid, conſidered as univerſal and denominated elementary fire; and hence it has been concluded, that hardneſs conſiſts in the abſence or deficiency of that element, called "latent heat." This is principally obſerved in the metals, and hence reſults their ductility; which property, as well as fluidity, depends altogether on a certain quantity of latent heat abſorbed, or acting within the ſubſtances themſelves; for all metals are rendered hard by hammering, and ſoft by being again kept for ſome time in the fire. The former operation renders them hot as well as hard; probably, ſays Dr. Black, becauſe the particles of metal are thus forced nearer one another, and thoſe of fire ſqueezed out from among them. By keeping them for ſome time in the fire, that element again inſinuates itſelf among the particles, and cauſes the ſame arrangement as they had before, and thus their ductility returns. By a ſecond hammering this property is again deſtroyed, returning on a repetition of the heating or "annealing." Hardneſs, it is ſaid, appears to diminiſh the coheſion of bodies in ſome degree. Though their fragility does not correſpond with their hardneſs. Glaſs is hard, but very brittle; whereas flint, though harder than glaſs, is much leſs brittle. With reſpect to metals, however, the caſe is different; for ſteel, the hardeſt of the metals, is the moſt brittle, but lead, the ſofteſt, is not the moſt ductile. Nor is hardneſs connected with the ſpecific gravity of bodies; for a diamond, the hardeſt ſubſtance in nature, is little more than half as heavy as the lighteſt metal. All bodies are hardened by cold; but ſome become hard by heat as well as by cold. Thus, water becomes hard by cold, when it is frozen; but it becomes much harder when its ſteam is paſſed over red-hot iron, and it enters the ſubſtance of the metal, by an union with which it becomes almoſt as hard as glaſs.

We ſhall here ſubjoin ſome obſervations reſpecting the hardneſs of different ſubſtances. The metals may be claſſed, according to Cavallo (Philoſophy, vol. ii) with reſpect to hardneſs, in the following order, beginning with the hardeſt and ending with the ſofteſt; iron, platina, copper, ſilver, gold, tin, and lead. The order of the ſemi-metals is as follows; manganeſe, nickel, biſmuth, tungſten, zinc, antimony, and arſenic. Steel may be rendered harder than any other metallic ſubſtance. Thus, if a piece of ſteel be heated red-hot, and in this ſtate be plunged in oil, it will become ſo hard, that a file will hardly ſcratch it; and it will be rendered ſtill harder, if, inſtead of oil, the red-hot ſteel be plunged in water; but if cold mercury be uſed inſtead of either oil or water, then the ſteel will be rendered ſo hard as to ſcratch glaſs nearly as well as a diamond. The hardneſs of other natural ſolids, beſides the metals, differs conſiderably, according to the ſtate of purity and various other circumſtances. An uſeful gradation of the principal natural ſolids, with reſpect to hardneſs, is exhibited in the following table, extracted from M. Magellan's edition of Cronſtedt's Mineralogy, which was taken from Quiſt's tables, from Bergman, and from Kirwan. The firſt column ſhews the hardneſs, and the ſecond the ſpecific gravity.

Diamond from Ormus	20	3·7
Pink diamond	19	3·4
Blueiſh diamond	19	3·3

N. B. This table was conſtituted by obſerving the order in which different ſubſtances are adapted to cut or make any impreſſion upon one another.

HARDOI, in *Geography*, a town of Hindooſtan, in Oude; 28 miles S.S.W. of Lucknow.

HARDOUIN, John, in *Biography*, was born at Quimper-Corentin in the year 1646. He was educated among the Jeſuits, and ſoon diſtinguiſhed himſelf by an extraordinary ardour for ſtudy, which he manifeſted in almoſt every branch of literary purſuit. In 1684 he publiſhed "Diſſertations on Ancient Medals of Towns and People," in which he diſplayed a turn for ſingular and paradoxical opinions. In the following year he publiſhed, for the uſe of the dauphin, an edition of Pliny the naturaliſt, of which he gave a ſecond edition in 1723, in ſeveral folio volumes. His moſt famous work was entitled "Chronologia ex Nummis Antiquis reſtituta," in which he attempts to prove that all the works attributed to the ancients, with ſome few exceptions, are ſuppoſititious, and the fabrication of the monks in the 13th century. This hypotheſis excited the indignation of the learned of every denomination and country, and drew upon the author the cenſures of his own ſociety. He retracted the opinions which, it is believed, he adopted by a mere love of ſingularity; for it is reported of him, that when urged by a friend with the ſcandal he had given by ſome of his abſurdities, he replied, "Do you think that I riſe every day of my life at four in the morning to repeat only what other people ſaid before me." Notwithſtanding this work he had a high reputation for learning among the clergy, and was by them employed, with an annual ſtipend, to prepare a new edition of the "Councils," which appeared from the Louvre preſs in 12 vols. folio. Parliament, however, ſtopped the circulation of the work till it had been examined and altered. He died at Paris in 1729, "having," according to Huet, "laboured 40 years to ruin his reputation without being able to effect it." He was author of many other works, in all which his paradoxical ſpirit was evident. Even in "A Commentary on the New Teſtament," there appears a mixture of profound erudition and viſionary paradox proper to this writer. Moreri.

HARDS, or Hurds, of flax or hemp, denote the coarſer parts ſeparated in the dreſſing of it, from the tear, or fine ſtuff.

Hards, in *Mining*, is applied to the harder kinds of vein-ſtuff, or rider, found in mineral veins.

Hards, in *Rural Economy*, a name often applied to coarſe tow, ſuch as is employed in ſtuffing horſe collars, &c.

HARDWIC. See Herdewic.

HARDWICK, in *Geography*, a townſhip of Caledonia county, in Vermont, containing 260 inhabitants.—Alſo, a townſhip of Worceſter county, Maſſachuſetts; 25 miles N.W. of Worceſter, containining 1727 inhabitants.—Alſo, a townſhip in Suſſex county, New Jerſey; 10 miles N.W. of Newton.—Alſo, a ſmall town and port of entry of Georgia, at the mouth of Ogeeche river, and about 18 miles S. by W. of Savannah.

Hardwick's *Iſland*, an iſland in Johnſtone's ſtrait, on the W. coaſt of North America, about 12 miles long from E. to W., and two broad. N. lat. 50° 26'. E. long. 134° 15'.

HARDY, a county of Virginia, about 60 miles long and 40 broad, containing 6004 free inhabitants, and 623 ſlaves. Its chief town is Moorfield.

Hardy's *Iſland, Sir Charles*, an iſland in the Southern Pacific ocean, ſo called by Capt. Carteret, who diſcovered it in 1767. This iſland is of conſiderable extent, flat, green, and of a pleaſant appearance: none of its inhabitants were ſeen, but it appeared by many fires that were ſeen in the night to be well peopled. It lies in S. lat. 4° 50', and bears W. 15 leagues from the northernmoſt of a cluſter of nine iſlands, called Ohang *Java*, which ſee.

Hardy's *Iſles, Sir Charles*, a group of high iſlands which lie at a diſtance of nine leagues from *Cape* Grenville, (which ſee,) in S. lat. 11° 58'. W. long. 217° 38'.

Hardy-*Shrew*, a name given by the people in ſome parts of England to the mus araneus, called more uſually the *ſhrew* or the *ſhrew-mouſe*. See Sorex *Araneus*.

HARDYSTONE, in *Geography*, a townſhip in Suſſex county, New Jerſey, containing, in 1790, 2393 inhabitants.

HARE, Francis, in *Biography*, a learned Engliſh prelate, was educated at Eton ſchool in the elementary parts of learning, whence he was entered at King's college, Cambridge, of which foundation he was admitted a fellow. Here he was entruſted with the tuition of the marquis of Blandford, whoſe father, the illuſtrious duke of Marlborough, appointed him chaplain-general of the army. When of a proper ſtanding he took his degree of doctor of divinity. While he attended the duties of his chaplaincy in Flanders, he contracted a ſtrong intimacy with doctor Bentley, who inſcribed to him the firſt edition of his "Remarks on a late Diſcourſe on Free Thinking, &c." Dr. Hare, during the period between 1706 and 1712, was often employed in vindicating the political meaſures of the Whig adminiſtration, and the conduct of the war in oppoſition to the Tory party. After this Dr. Hare was promoted to the deanery of Worceſter, and united with Dr. Sherlock and others in the famous Bangorian controverſy. The part which he took drew upon him a ſevere caſtigation from biſhop Hoadley, in a treatiſe entitled "The D—n of W—r ſtill the ſame, &c." In the year 1727 he was advanced to the ſee of St. Aſaph; from this he was tranſlated to the biſhopric of Chicheſter in 1731, which he held, in conjunction with the deanery of St. Paul's, till his death in 1740. The moſt celebrated of Dr. Hare's productions was a treatiſe, entitled "The Difficulties and Diſcouragements which attend the Study of the Scriptures in the way of private Judgment, repreſented in a Letter to a Clergyman," which has been regarded as one of the fineſt pieces of irony in the Engliſh language: the great object of the tract was, "that ſince ſuch a ſtudy of the ſcriptures is men's indiſpenſable duty, it concerns all Chriſtian ſocieties to remove, as much as poſſible, thoſe diſcouragements." Dr. Hare was author of various other works, and of ſome ſingle ſermons. He gave an edition of Terence to the public, and publiſhed "The Book of Pſalms in Hebrew, put into the original Poetical Metre." The works of the biſhop were collected in four vols. 8vo., in the year 1746. Gent. Mag. Gen. Biog.

Hare, in *Aſtronomy*. See Lepus.

Hare, in *Zoology*. See Lepus.

What is moſt particular in the hare is, that the hinder legs are much longer than the fore ones, and are furniſhed with extremely ſtrong muſcles; by which means the creature, naturally defenceleſs, is furniſhed with a power of running very ſwiftly from its purſuers, and of aſcending ſteep places; and on this account the hare always makes towards the riſing ground when ſtarted. The head is roundiſh, the eyes prominent, and the upper lip ſplit; its ears are very long; and it is ſaid to ſleep with its eyes open, for fear of danger; it lies hid all day, but in the night goes out in ſearch of food, and returns to its form by the ſame way, by which it had left it.

The colour of the hare approaches near to that of the ground; and in northern countries this, as well as other animals, changes colour, and becomes white at the beginning of winter, ſo that they are leſs conſpicuous in the ſnow: we have accidental inſtances of white hares. The food of this animal

animal is entirely vegetable; and it is particularly fond of pinks, parſley, and birch. The hare never pairs; but in the rutting ſeaſon, which begins in February, the male purſues and diſcovers the female, by the ſagacity of its noſe. The female breeds often in the year; goes with young a month, and brings uſually two, and ſometimes three or four, at a time. Hares are very ſubject to fleas; and Linnæus tells us, that the Delecarlians make a ſort of cloth of the fur, called filt, which preſerves the wearer from their attacks. The fur of hares is a very conſiderable article in the hat manufacture, and many thouſands of the ſkins are annually imported for that uſe from Ruſſia and Siberia.

The ſportſmen diſtinguiſh four ſorts of this animal: the one lives in the mountains; the ſecond kind in open fields; a third kind in marſhy grounds; and the fourth is a rambler, having no particular fixed ſpot of reſidence. It is eaſy to ſee that theſe are no diſtinctions in the eye of the naturaliſt; but they have their ſeveral properties, according to theſe differences of place, which are of conſequence to the ſportſmen. Thus the mountain hares are the ſwifteſt of all, and the marſh hares the ſloweſt; the field hares have a middle degree of ſwiftneſs between theſe; and the rambling hares are the moſt difficult of all others to hunt, for they are not only conſiderably ſwift, but they generally know all the coverts and thickets, and have the art to make a thouſand doublings and eſcapes that the others would not think of. See *Hare*-Hunting.

Hares and rabbits are very miſchievous to new-planted orchards, by peeling off the barks of the tender and young trees for their food. They do alſo the ſame ſort of miſchief to nurſeries; for the prevention of which ſome bind ropes about the trees up to ſuch a height as they are able to reach; ſome daub them with tar; but though this keeps off the hares, it is itſelf miſchievous to the trees; but this hurtful property of it is in ſome degree taken off by mixing any kind of fat or greaſe with it, and incorporating them well over the fire. This mixture is to be rubbed over the lower part of the trees in November, and will preſerve them till that time the next year, without any danger from theſe animals. It is only in the hard weather in the winter ſeaſon, when other food is ſcarce, that theſe creatures feed on the barks of trees.

People who have the care of warrens, pretend to an odd way of making hares fat when they get them there. This is the ſtopping up their ears with wax, and rendering them deaf. The hare is ſo timorous a creature, that ſhe is continually liſtening after every noiſe, and will run a long way on the leaſt ſuſpicion of danger; ſo that ſhe always eats in terror, and runs herſelf out of fleſh continually. Theſe are both prevented by her feeding in a ſafe place, and that without apprehenſion; and they ſay ſhe will always readily be fattened in this way.

However delicious the hare may be eſteemed now, our anceſtors thought it a crime to taſte it, as we learn from Cæſar, Com. lib. v. in which they agreed with the Jews. Among the Romans it was reckoned a great delicacy. Thus Martial, xiii. 92.

"Inter quadrupedes gloria prima lepus."

And Horace, in the ſecond ſatire of his fourth book, extols the wing of the fruitful hare:

"Fœcundi leporis ſapiens ſectabitur armos."

Though the hare lives on vegetables and water only, yet the habitual exerciſe of this animal exalts its ſalts, and renders it ſomewhat alkaleſcent; and this tendency is much increaſed, if it is killed immediately after being heated by ſtrong exerciſe.

Hare, in *Geography*, an iſland in the North ſea, near the coaſt of Norway, 20 miles in circumference. N. lat. 62° 20'. E. long. 6° 33'.

Hare *Bay*, a bay on the E. coaſt of Newfoundland. N. lat 51° 20'. W. long. 55° 40'.

Hare *Indians*, Indians of the N.W. part of America, ſituated on Mackenzie's river. N. lat. 66° 50', and between 127° and 130° W. long.

Hare-*Lip*, (Labia leporina,) in *Surgery*, is a particular deformity of the lip, which part has a preternatural fiſſure in it, the roof of the mouth itſelf being alſo ſometimes imperfect.

The hare-lip is generally a defect of original formation, and is therefore obſerved in children of tender years. The deformity, indeed, is ſometimes the conſequence of a wound; but this caſe is by no means frequent. The upper lip is that which is uſually affected, it being only in ſome uncommon caſes that a fiſſure is met with in the lower one. The edge of the congenital hare-lip is healthy, ſoft, red, covered with a delicate cuticle, and, in every reſpect, ſimilar to the ſurface of the lips. It is only when the fiſſure is the effect of a wound or ſore, that its edges are ſometimes uneven, hard, and callous. The lip is ſometimes divided only in one place, ſometimes in two. When the two fiſſures are ſomewhat diſtant aſunder, the intervening piece of the lip may be of ſuch breadth and length, that it will be of uſe to ſave it in the operation. However, this ſort of caſe is not common, and the two fiſſures are generally ſo near together that they appear rather like one, at the upper angle of which the intervening piece of the lip is ſituated, ſeeming like a ſmall knob of fleſh.

Sometimes, the preternatural fiſſure only extends to the middle of the lip; but, on other occaſions, it reaches to the noſe, and even quite into one of the noſtrils. In this laſt caſe, the fiſſure is not only very broad, but the noſtril is alſo ſtretched to one ſide, and, conſequently, the noſe appears much wider on one ſide than the other. Beſides the cleft in the lip, a fiſſure is likewiſe frequently obſerved in the upper jaw and palate bones, and is often ſo large as to convert, as it were, the inſide of the mouth and noſe into one common cavity. Occaſionally, there is a ſlit in the gums, which, however, is generally ſituated quite on one ſide of the diviſion in the bones. In certain inſtances, a protuberance is met with on the upper jaw bone, forming a projection through the fiſſure in the lip. In grown perſons, a tooth is ſometimes ſeen protruding out of the fiſſure.

The hare-lip not only always produces more or leſs deformity, but alſo ſeveral complaints, which principally make their appearance when the patient advances in years. Perſons, who labour under this defect, cannot pronounce the letters well, eſpecially ſuch as are formed by the lips, and they likewiſe articulate words in an indiſtinct way. In ſpeaking they ſlobber, and in maſticating ſome of the victuals are apt to fall out of their mouths. The tooth behind the fiſſure is uncovered, and is either liable to project conſiderably forward, or to become carious. Such children, alſo, as have a cleft in the bones of the palate, are incapable of ſucking, and frequently they are not even able to ſwallow fluids.

fluids. Every liquid, which is introduced into the mouth, gets into the noſtril, and thence eſcapes outward. It is worthy of attention, that ſimilar congenital fiſſures are not unfrequently met with in other parts, as, for inſtance, in the cartilaginous parts of the noſe, the external ear, the eye-lids, &c. Theſe latter defects may be cured preciſely in the ſame way as the hare-lip.

The operation is the only plan by which the fiſſure may be united, and the conſequent deformity removed. In order to unite the fiſſure two things are neceſſary, namely, that its margins ſhould be converted into freſh-cut ſurfaces, and that theſe ſhould afterwards be brought into contact in ſuch a manner that they touch at all points. The operation commonly ſucceeds, even when the fiſſure is exceedingly broad and large. Although, in Richter's opinion, the fiſſure is not always, as M. Louis conceives, a mere diviſion of the parts, but is ſometimes plainly occaſioned by a conſiderable deficiency or loſs of ſubſtance, yet the lips are naturally ſo yielding, that there is always leſs trouble experienced in bringing the edges of the fiſſure into contact, than many would be inclined to ſuppoſe. The ſpaſms and contractions of the lip, which in theſe caſes are apt to take place ſoon after the operation, in general gradually ſubſide, or at leaſt undergo ſuch a diminution, that they ſcarcely ever give riſe to any deformity of conſequence. It ought to be well underſtood, however, that the breadth of the fiſſure, in the majority of inſtances, is altogether the effect of the action of the muſcles, and not of any actual loſs of ſubſtance, the edges of the diviſion being drawn away from each other by the contraction of the neighbouring muſcles.

From what has been ſaid, it muſt be manifeſt how ſuperfluous the plan is, which ſome have recommended, where the fiſſure is large, and which conſiſts of ſome preparatory proceedings, before the operation, adapted to promote the yielding of the lips, and the union of the edges of the fiſſure. For example, were we to follow the advice of ſome ſurgical writers, we ſhould draw the oppoſite ſurfaces of the hare-lip together, for ſome days before the operation, with bandages and adheſive plaſters, in order to habituate the lip to be upon the ſtretch. We ſhould likewiſe, according to the ſame ſet of adviſers, make an inciſion in the ſkin, both on the outſide and inſide of the lip, a little while before the operation, for the purpoſe of making this part yield in a greater degree. Such inciſions are not of the leaſt utility, ſince they only divide the ſkin, and it is not this, but the muſcles, which oppoſe the yielding of the lip. Beſides, the external cut will occaſion a ſcar, and, of courſe, be followed by deformity. The application of bandages and adheſive plaſters, for a few days before the operation, may perhaps have the effect of accuſtoming the child to the uneaſineſs of ſuch an apparatus, and making the little patient rather more quiet after the operation is done; or, it may habituate adults to ſpeak and eat, without moving their lips much, which will be of ſervice after the operation. However, the plan is entirely uſeleſs, when done with a view of ſtretching the lips, and facilitating the approximation of the edges of the fiſſure.

A queſtion naturally preſents itſelf, whether it is preferable to perform the operation ſoon after birth, or to defer it till the child has advanced in life? The deſire, which parents have, of freeing their offspring, as ſoon as poſſible, from any kind of diſfigurement, will generally oblige the ſurgeon to do the operation at an early period. He may the more readily make up his mind to this practice, as the ſucceſs of the operation on infants has been eſtabliſhed by repeated experience. It happens, that young children almoſt always fall into a ſleep, and, conſequently, the dreſſings are not diſturbed by any crying, or reſtleſſneſs, nor the wound torn open, circumſtances, which are to be apprehended in larger children. Experience alſo proves, that wounds in very young infants heal with particular eaſe and quickneſs. The objection, that the operation, when performed on children of very early age, is apt to bring on dangerous and even fatal conſequences, is, according to Richter, without foundation. There is no part of conſequence injured, and the inflammation which enſues is never of any importance. Nor is there more reaſon in the aſſertion, that, in children of tender years, the ſutures are apt to cut their way out, by reaſon of the tenderneſs of the lips. When the lip is properly dreſſed, this accident is little to be feared in infants which are continually quiet and aſleep. The operation is attended with more difficulty in children of from three to ten years of age, who are fearful of pain, and cannot be rendered tractable either by threats or reaſoning. When the operation is not done ſoon after birth, ſome ſurgeons believe it better not to perform it till the child has attained a certain degree of underſtanding and reflection.

When, beſides the fiſſure in the lip, there is alſo a cleft in the bones of the palate, we have ſtill more reaſon for performing the operation ſoon after birth; for it has been remarked, that the ſeparation in the bones is never cloſed before the hare-lip is cured, and that ſuch cloſure may not happen at all, if the operation is long poſtponed. (Levret, l'Art des Accouchemens, § 1321. La Faye Mem. de l'Acad. de Chir. tom. 3. edit. 8. p. 201.)

When there is alſo a fiſſure in the upper jaw-bone, and the diviſion of the lip extends into one of the noſtrils, and is exceedingly broad, it is advantageous, before the operation, to detach the edges of the cleft in the lip from the gums to the breadth of a quarter, or half an inch. Thus, not only the elongation of the lip, and the cloſure of the fiſſure are promoted, but the cutting off of the edges of ſuch fiſſure is facilitated. Sometimes, in this caſe, the border of the cleft adheres very intimately to the gums, and diviſion in the jaw-bone, in which circumſtance the foregoing ſeparation is indiſpenſably neceſſary. Should the fiſſure reach quite up into the noſe, the lip muſt be detached with a knife from the gums, as high as above the upper end of the fiſſure, ſo that the ſurgeon may be enabled, in the operation, to cut off the upper part of the edges of the fiſſure. Frequently a piece of fleſh is found ſituated in the middle of the diviſion in the lip, looking like a little excreſcence from the gums. This muſt be taken away before the operation. When, in adults, a tooth projects forwards into the fiſſure, it muſt be extracted. When there is a kind of exoſtoſis of the jaw-bone, ſuch ſwelling ought to be removed. Perhaps the object might be beſt fulfilled by means of a pair of bone-nippers, or one of Mr. Hey's ſaws.

It is now the univerſal practice to remove the edges of the fiſſure in the lip with a cutting inſtrument. With a view of doing away the neceſſity for this painful part of the operation, it has been propoſed to apply bliſtering plaſter to the fiſſure, or to ſmear it by means of a hair pencil, with a ſolution of cauſtic, or with ſulphuric acid, ſo as to make it ulcerate. However, as it is not merely the union of the fiſſure, but alſo the total prevention of all diſfigurement that we wiſh to accompliſh, ſuch means are exceedingly objectionable. They only make the margin of the fiſſure ulcerate; they cannot render it even when it is irregular; conſequently no exact union, nor any favourable cicatrix, can be the reſult. Hence, the employment of a cutting-inſtrument muſt manifeſtly be attended with immenſe advantage, not to ſay

ſay any thing about the difficulty of uſing the preceding applications on young infants, or the danger of the adjacent parts, the tongue, gums, under lip, &c. being injured.

Some ſurgical writers recommend the operation to be done with ſciſſars. However, as ſciſſars always bruiſe the fibres, at the ſame time that they divide them; and as ſuch contuſion invariably renders union by the firſt intention leſs certain, we coincide with thoſe authors who give the preference to the employment of a knife. This inſtrument makes the cleareſt diviſion of the parts, the cut fibres being neither torn nor contuſed. Grown-up perſons may be prepared for the operation, if the practitioner thinks proper, by a gentle purgative. Young children, on the day of the operation, may be awakened early, and hindered from ſleeping till the buſineſs is over, by which means they become drowſy, and immediately after the operation, when the pain is greateſt, fall aſleep, ſo that there is no danger of the dreſſings being diſturbed by reſtleſſneſs and crying. In the operation, adult patients may ſit upon a chair; infants ſhould be held on the nurſe's knee. Surgeons will find it very diſadvantageous to operate on children in a recumbent poſition; for in this poſture, the blood inſinuates itſelf into the mouth, and occaſions, particularly when the infants cry, violent coughing, and ſymptoms of ſuffocation. An aſſiſtant ſhould ſtand behind the patient, and with his breaſt keep the head from being drawn backward. He ought alſo to apply his hands to the patient's cheeks, and when the ſurgeon makes the margins of the fiſſure approximate each other, he ſhould preſs the cheeks gently forwards, in order to promote what the ſurgeon is wiſhing to accompliſh. In children, the aſſiſtant, at the time when the practitioner is executing the inciſion, ſhould place his hands cloſe upon the cheeks, ſo as to keep the edges of the fiſſure from being drawn away from each other by the childrens' crying, an event which would increaſe the difficulty of the operation.

Another thing to be conſidered is, how much of each edge of the fiſſure ought to be cut off? It is always right to remove as little as poſſible, ſo as not to make the loſs of ſubſtance greater than is abſolutely neceſſary, and increaſe the difficulty of bringing the ſides of the fiſſure into contact, particularly when the ſeparation is already very wide. However, the exact deciſion of this queſtion depends upon the following circumſtances. The whole margin of the fiſſure muſt be completely converted into a bleeding ſurface at every point. When any portion continues uncut, no union will follow in ſuch ſituation, and an unhealed opening remains there in the lip. On this account, the ſurgeon is ſometimes obliged to remove a conſiderable piece of the lip when the edges of the fiſſure are uneven and angular. On the contrary, when the edges are ſtraight and regular, it frequently happens that very little need be cut off. It is alſo abſolutely neceſſary, for the purpoſe of effecting a preciſe union, and forming a favourable cicatrix, that the border of the fiſſure be removed by an even ſtraight inciſion. For this reaſon, the regularity or irregularity of the edges of the fiſſure is what muſt determine whether little or much of the lip ſhould be taken away. It is further neceſſary, in making the inciſions, to give the fiſſure the ſhape of an equal triangle, or rather that of the annexed figure A, the angle of the wound being above. Were one ſide of the fiſſure longer than the other, the lower corner of the longeſt ſide, after the union had taken place, would deſcend below the lower end of the ſhort ſide, ſo as to occaſion not merely a great diſfigurement, but conſiderable inconvenience. The neceſſity of making the diviſion into the ſhape of a triangle with equal ſides, is another circumſtance which muſt have weight in deciding whether much or little of the lip is to be removed. When the fiſſure is of ſuch a ſhape, that, in order to give it the right form, it would be neceſſary to cut off a very conſiderable piece of the ſubſtance of the lip, the practitioner, perhaps, ought not to bind himſelf by the preceding maxims, eſpecially when the fiſſure is already very broad, and the approximation of its edges difficult. In this caſe, it might be better, after bringing the ſides of the wound into contact, to cut off the projecting corner of that ſide which is too long, and thus render the lip even.

It has been already remarked, that the edge of the congenital hare-lip, like the border of the natural lip, is commonly of a red colour, and covered with a fine cuticle. When the edge of the fiſſure is not cut off as far as it is red, a red mark is left behind in the place, occaſioning no inconſiderable diſfigurement. Hence it is always requiſite to remove more or leſs of the lip, according as the red edge of the fiſſure is more or leſs broad. The lower angles of the diviſion in the lip are frequently very round and thick, reſembling very much two red knobs of fleſh. In this kind of caſe, when only a little of the edge of the fiſſure is cut away, a ſmall cleft will be left after the cure at the lower part of the wound, together with a round fleſhy prominence on each ſide, which appearances are productive of a great deal of deformity. In order to prevent this diſagreeable circumſtance, it is neceſſary, in ſuch caſes, to cut away the greateſt part, if not the whole, of the round ſwollen angles of the fiſſure. Young practitioners, who have not been much in the habit of operating, may derive ſome aſſiſtance from marking the proper direction of the inciſions with ink.

We have explained, that the beſt operators have abandoned the uſe of ſciſſars for removing the edges of the hare-lip, and always give the preference to the knife. However, if ſciſſars are ever employed, they ought to be conſtructed with long handles and ſhort blades, and it might alſo be advantageous to have the blade probe-pointed, which is introduced under the lip. We hope, at the ſame time, that we ſhall never be diſguſted with the ſight of ſciſſars being employed in this country for the accompliſhment of the operation now under conſideration.

The ſurgeon ſhould remove each edge of the fiſſure by a ſingle inciſion; for when repeated cuts are made, the wound is always irregular, and every time the knife is applied, young children become reſtleſs, and are not quiet again for a while, ſo that the operation is tediouſly protracted.

The lips being exceſſively moveable, it is obvious, that in order to execute the operation well, ſome plan muſt be adopted for keeping the part which is to be cut ſteady and fixed. Heiſter and B. Bell have given engravings of forceps calculated for holding the lip. Such an inſtrument we have ſeen uſed, and it appears to us by no means an ineligible one. It fixes the part exceedingly well, and as much of the edge of the fiſſure being left out of the blades as is judged proper, ſuch portion can be moſt eaſily cut off by one ſweep of the ſcalpel guided along the ſtraight line of the inſtrument. It is right to obſerve, however, that the blades of the forceps ought to be ſo contrived as to be parallel to each other when opened, and to graſp every point of the lip with equal preſſure when cloſed. The objection urged againſt the uſe of the inſtrument, that it is apt to pinch and bruiſe the lip, is frivolous, the neceſſary degree of preſſure for fixing the part not being in reality ſuch as will do the leaſt harm. The ſurgeon often does much more injury

jury with his nails in endeavouring to hold the lip. We have ſeen forceps uſed in this operation with the blade, which is put under the lip, much wider than that which is external, and which is made to ſhut upon the middle of the other. By this means the lip is ſo fixed, that it cannot ſlip inward away from the knife, which, in fact, cuts upon the flat ſurface of the under blade of the forceps, while the edge of the upper blade ſerves to guide the ſtroke of the inſtrument, as well as to keep the part fixed.

It cannot be denied, indeed, that the practitioner is not conſtantly able, by obſerving any directions, to take away the edge of the fiſſure, on one ſide or the other, by a ſingle inciſion, and he is ſometimes obliged to be content with removing as little ſubſtance as poſſible. He muſt alſo take care, while he holds the lip, not to ſtretch the part too much, nor draw it into an unnatural poſition; for the wound naturally aſſumes a different ſhape, and falls into a different poſture from that which it had at the time of the inciſion, immediately the lip is looſened; and the ſurgeon muſt always have in view the bringing of the edges of the wound into exact contact. With the forceps it will be found a very eaſy matter to obſerve theſe things, though more troubleſome when the lip is held with the fingers. Laſtly, it is eſſentially neceſſary to make the upper angle of the wound quite even, and to terminate in a point. Were any irregularity, or any ſmall piece of fleſh left there, the ſides of the inciſion could not touch in ſuch ſituation, and an opening would be left. When the fiſſure extends completely into one of the noſtrils, it is, indeed, not in the ſurgeon's power to give the wound a triangular ſhape; but he muſt not neglect to cut off the edges of the cleft, on both ſides, up to the noſtrils, in ſuch a way, that the two ſides of the wound will be of equal extent.

It was the eminent ſurgeon, M. Louis, who firſt ſtrongly recommended the uſe of a knife, inſtead of ſciſſars, in this operation. (See Mémoires de l'Acad. de Chirurgie de Paris, tome 4.) He very properly objected, that ſciſſars make a contuſed wound, which is apt to inflame and ſuppurate, or which, at leaſt, is not diſpoſed to heal quickly. Conſequently, ſciſſars are not only adverſe to the main object of the operation, union by the firſt intention; but their employment is attended with an unavoidable degree of pain. The knife produces leſs pain, is of more convenient uſe, and makes a ſimple, inciſed wound, which is not diſpoſed to ſuppurate, and uſually heals up in a very ſhort time.

Beſides forceps for fixing and ſupporting the lip at the time of removing the edges of the fiſſure, there are other methods, which are, perhaps, in more common adoption among the moderns. Some practitioners are in the habit of firſt introducing under the upper lip, as high up as poſſible, a piece of thick paſteboard, an inch and a half long, from twelve to fifteen lines broad; and cut into a ſemi-lunar ſhape at its upper border. Upon this bit of paſteboard the upper lip is to be ſpread, and, at the ſame time, drawn a little downwards, by which means the part is rendered tenſe, and can be readily cut through. The right portion of the lip is to be fixed on the paſteboard, with the thumb and index finger of the operator's left hand. The left, however, muſt be fixed with the aid of an aſſiſtant. The ſurgeon is next to puſh the point of the knife through the lip, above the upper angle of the fiſſure, and, drawing the inſtrument downward, he is to cut off, with two ſtrokes, all that is to be removed on both ſides. While theſe things are being done, an aſſiſtant, ſtanding behind the patient, is to apply a hand to each of the latter's cheeks, which are to be preſſed a little forward with the point of the finger, ſo as to hinder the patient from drawing the lip backward, and ſeparating the edges of the fiſſure from each other. Some ſurgeons prefer the uſe of the forceps to that of paſteboard, as being more convenient, and ſerving not only to fix the lip and direct the knife, but having likewiſe an under broad blade, making a flat ſurface, upon which the border of the fiſſure reſts, and with the knife can be eaſily cut off.

Although all the beſt operators of the preſent day in England make uſe of a biſtoury inſtead of ſciſſars, the latter inſtrument is ſtill defended in ſome very modern works. It is acknowledged that the knife appeared to be the moſt eligible, on account of its making a ſimple inciſed wound, which is the moſt likely to heal by the firſt intention; but yet it is contended, that manifold experience ſhews, that the wound heals equally well and quickly when good ſharp ſciſſars are employed in the operation. Mr. B. Bell has expreſsly made the experiment of removing one edge of the hare-lip with the knife, and the other with a pair of ſciſſars, and he found, that there was not more inflammation afterwards on one ſide than the other. It is urged in favour of ſciſſars, that they make an inciſion more quickly than the knife, a circumſtance of importance in operating upon reſtleſs children. The advocates for ſciſſars upon this principle, explain their aſſertion, that patients complain of leſs pain when cut with this inſtrument, than when the biſtoury is uſed. They affirm, that an operator can much more eaſily cut off each edge of the fiſſure by one ſtroke of a pair of ſciſſars than by one of a knife, which muſt often be repeatedly applied before the object can be effected. They recommend uſing the beſt and ſharpeſt ſciſſars which can be procured. They further ſtate, that caſes are met with, in which the cleft extends quite up into the noſtril, and in which a piece of paſteboard cannot be inſinuated under the lip, as high as it is neceſſary to make the inciſion. Here they ſay the knife cannot be made uſe of, and it is requiſite to ſeparate the lip freely from the gums on both ſides of the fiſſure. They untruly declare that a ſcalpel is an inconvenient inſtrument for removing a cancer of the lower lip. They contend, that a knife ought not to be uſed on very young infants. They ſay, that in caſes of double hare-lip, it is difficult, and even impracticable, to cut off with a biſtoury the edges of the middle portion of the lip, which is in general exceedingly moveable.

We do not deem it neceſſary to enlarge the preſent article, by entering into a formal refutation of the foregoing obſervations. If it be admitted, that ſciſſars contuſe as well as cut, and that a ſharp knife makes a cleaner and more ſimple inciſion, the latter inſtrument ought to have the preference, as in fact it has among all our beſt operators. We have ſeen the knife uſed with perfect convenience upon infants, and likewiſe in a few caſes of double hare-lip and reputed cancers. This is enough to prove what little foundation there is for moſt of the above aſſertions.

The ſecond part of the operation, or the union of the ſides of the wound, is uſually accompliſhed by means of the twiſted ſuture, for which pins of a particular conſtruction are made. Theſe muſt be fabricated with ſharp points, ſo as to be well calculated for entering the fleſh with eaſe; and they ought to be ſuch as will not ruſt in the wound, and of courſe can be withdrawn without irritation. Silver and golden pins are not apt to ruſt; but they are not capable of having a ſtrong ſharp point given to them, and, conſequently, are difficult of introduction. Steel pins penetrate well. However, they are liable to ruſt, and therefore cannot be taken out of the parts without irritation, nay, frequently, not without the exertion of force, and a conſider-

able danger of the wound being torn open again. Silver and golden pins, made with ſteel points, which can be ſcrewed off, are the beſt, as they cannot ruſt, nor prick any part, nor irritate the wound. Richter alſo ſpeaks rather favourably of ſteel needles plated with ſilver or gold. The points of the pins ought to be ſmall, and two-edged. Pins with round points cannot be puſhed into the fleſh without difficulty. The ſame may be ſaid of triangular points. Mr. B. Bell recommends the pins to be made long, ſo as to admit of being more eaſily handled. Richter thinks ſuch conſtruction objectionable, as the pins then project a conſiderable way out of the fleſh on each ſide, a thing which, on many accounts, he deems diſadvantageous.

Two pins are uſually ſufficient for the union of the wound. It is always neceſſary to apply one of them near the lower edge of the lip, otherwiſe the angles of the wound become ſeparated, and a ſmall cleft is left behind. When the hare-lip reaches into the noſtril, and the patient's upper lip is rather long, three pins are requiſite, one of which muſt be introduced cloſe to the noſtril. The pins are commonly put in about three or four lines from the margin of the wound, and brought out again at the ſame diſtance on the oppoſite ſide. When the fiſſure is long and broad, ſeeming as if it were attended with a loſs of ſubſtance, Richter adviſes us to introduce one of the pins at a ſomewhat greater diſtance from the edge of the wound, ſo as not to be apt to cut through the lip by ulceration, a circumſtance which, in this kind of caſe, is always to be apprehended, eſpecially when the patient is reſtleſs and unmanageable, and the pins are not aſſiſted with another means of uniting wounds.

The pins muſt be ſo applied as to paſs through very near the inner ſurface of the lip. When they are introduced through the middle of the ſubſtance of the part, or juſt under the ſkin, the inner edges of the wound are brought into contact, and there remains during life, upon the internal ſurface of the lip, a furrow, which is exceedingly diſagreeable to the patient. Beſides, the bleeding from the poſterior part of the fiſſure frequently does not ſtop, when the ſurgeon neglects to bring the oppoſite ſurfaces of the wound properly together. In putting in the pins, the ſides of the wound ſhould not be brought into contact, as it is much more advantageous, in this part of the operation, to ſeparate them a little from each other, by which means the practitioner is enabled to ſee that the pin goes to the proper depth, ſufficiently near the inſide of the lip. The lower pin is always to be introduced firſt, in order to bring the lower angles of the wound into accurate contact. Were the upper pin put in firſt, we ſhould frequently find, in the end, one ſide of the wound reach lower than the other, and, conſequently, one of the angles of the wound lower than its fellow.

Sometimes, on making the requiſite inciſions, the bleeding is conſiderable, but it never fails to ſtop as ſoon as the ſurfaces of the wound are brought together with the pins, and therefore it demands no particular treatment. It is only neceſſary to take care, as has been already explained, to introduce the pins almoſt as deep as the inſide of the lip, ſo as to keep the internal edges of the wound in cloſe contact with each other, otherwiſe the hemorrhage would continue inwardly into the mouth, particularly in children, who are apt to keep ſucking the wound, and, as the blood is ſwallowed, the bleeding is in danger of not being diſcovered. Experience has evinced, that ſometimes death may be occaſioned in this manner. In order to avoid this accident, ſome writers recommend enjoining the patient to ſwallow nothing after the operation, but to get rid of his ſaliva by ſpitting. However, as this plan would produce conſiderable diſturbance of the wound, we cannot aſſent to ſuch advice, eſpecially as the practitioner may always aſcertain whether there is any inward bleeding, by juſt looking into the patient's mouth. Many deem it advantageous not to bring the ſides of the wound into contact immediately the inciſions are executed; but firſt to let the bleeding go on for a little while, ſo as to diminiſh the chance of too much inflammation coming on.

As ſoon as the lower pin is applied, ſome authors direct us to wind a bit of thread round it, for the purpoſe of keeping the wound from being forced open, and the pin puſhed out when the operator is introducing the ſecond. This plan, at beſt, is unneceſſary. When the pins are both put through the lip, in the way above related, a thread is to be wound round them in the form of the figure of 8. The threads ſhould be ſtrong and waxed, in order to keep them from imbibing any fluid. They ought to be applied with ſufficient, but not immoderate tightneſs. When they are not tight enough, the lips of the wound are not effectually ſupported at every point, and the bleeding ſometimes continues till they are drawn tighter; when they are too tightly applied, they make the wound painful and inflamed. The two circular portions of fleſh, which the thread quite ſurrounds, in particular ſuffer from the exceſſive preſſure; they ſwell up like little eminences, and often project in this way a long while after the cure is accompliſhed. Occaſionally they inflame and ſlough. Hence it is always adviſable to tie the thread in a ſlip-knot, by which means it may be eaſily tightened or ſlackened as circumſtances may require.

Some ſurgeons have adopted the plan of cutting off the points of the pins after winding the thread. They do this that the lip may not be hurt by them. Others have covered the points with a piece of wax or ſponge. Theſe latter ſubſtances ſoon ſlip off, and are of no uſe whatever. The points can hardly be cut off without doing the wound ſome kind of violence. Beſides, they are ſo far from the lip that they cannot injure it in the leaſt; but it is diſadvantageous to have pins with points projecting a good way out of the lip, as the patient is liable to put his hands againſt them, hurt himſelf, and diſturb the wound. Shortiſh pins, with points made to ſcrew off, are to be preferred.

As the fore part of the upper jaw-bone on which the lip lies, and conſequently the lip itſelf, are not ſtraight but curved, it has been apprehended that the ſtraight pins, which are employed in this operation, might draw the lip into a ſtraight unnatural poſture, thus irritate it, make it painful and inflamed, and fruſtrate the healing of the part by the firſt intention. Hence it has been propoſed to uſe ſilver or golden needles, to which is given the degree of curvature natural to the lip. However this is unneceſſary, becauſe the part of the needle, which actually lies in the ſubſtance of the lip, is ſo ſhort that it can produce no alteration in the ſhape and poſition of the lip. The plan is even objectionable; for as ſoon as the thread is wound round the curved pin, this generally turns in ſuch a way, that its concavity becomes ſituated externally, and the curvature of the lip being forced by it inwards, the part is much more deformed, than by a ſtraight needle.

The interrupted ſuture which Chopart has recommended to be uſed for the hare-lip, has no advantage whatſoever over the twiſted ſuture, the pins not irritating the wound more than the ligatures. On the contrary, the interrupted ſuture is uſually productive of the moſt irritation, becauſe, in order to keep the ſides of the wound nicely in contact, it is neceſſary to apply a greater number of ligatures than pins. The threads, which croſs each other in the interſpace between the

the pins, keep that part of the wound exceedingly well closed, even when the pins are at a considerable distance apart.

M. Louis, in the fourth volume of the Mémoires de l'Academie de Chirurgie, has altogether condemned what have been termed the *bloody sutures* in the operation for the hare-lip, and has advised merely employing a uniting bandage and adhesive plaster for bringing the wound together. He represents these means as fully effectual in all cases. The pins of the twisted suture, he observes, bring on inflammation and suppuration, in consequence of the wound which they occasion, and the irritation they excite as foreign bodies. Hence, says M. Louis, they must be diametrically adverse to the great aim of the surgeon, which is to accomplish union by the first intention. Besides, it is an observation made by this eminent surgeon, that the most certain and easy method of bringing the separated lips of the wound into contact, does not consist in bringing some other resistance against the power which makes the wound gape, but in preventing this latter power from operating at all. This object may be effected by the uniting bandage, which hinders the cheeks, in which such power is situated, from drawing the lip to each side, at the same time that it supports the part and keeps it forward. The surgeon, in employing the twisted suture, only opposes the power in question by another one. The power which makes the sides of the wound separate here acts quite unrestrained; and, when the pins resist it the lip of course is stretched, and continually in an irritated state, which is followed by pain and inflammation. When the power alluded to acts with force, the pressure of the pins hurts the wound and makes it inflame; and there is a danger of their cutting their way through the flesh and dropping out. Lastly, it is noticed by M. Louis, that the hare-lip is commonly supposed to originate from an actual deficiency of substance in the lip, which idea makes surgeons fancy bandages and sticking plaster insufficient for keeping the widely separated edges of the wound in contact, and that pins or ligatures are indispensable. But it ought to be recollected that the harelip never proceeds from a loss of substance, but only from a preternatural division of the part. It is argued, that in cases where there is most difficulty in bringing the sides of the wound together, the twisted suture is least applicable and effectual, since the pins make their way through the edges of the wound and fall out. For the sake of corroborating the foregoing observations, M. Louis cites cases where cures were effected in the happiest way with the mere employment of a bandage, and other cases where the attempts failed with the twisted suture.

Many kinds of bandages have been proposed for uniting the hare-lip; but to give an account of them all in this place would be falling into prolixity. Here we can only mention the principal ones. The bandage, which M. Louis was in the habit of employing, and which he preferred to all others, was an inch broad, and three ells long. He applied it first over the forehead, and both ends were carried behind the ears, and then to the hinder part of the neck, where they crossed. They were next conveyed forwards over the cheeks, upon each of which a compass was laid, and the extremities of the roller were then carried over the lip itself, where one end was drawn through a slit in the other. They were afterwards carried behind the ears, and to the nape of the neck again. The rest of the bandage was spent in circles round the head. In order to prevent the apparatus from slipping, a fillet was applied from the forehead across the top of the head to the nape of the neck, while a similar piece of tape went across this first one from one ear to the other. These cross-bands were stitched to the circles of the uniting bandage. We are assured that the foregoing bandage always kept its proper place, and answered every expectation.

Some have proposed using an elastic steel semicircle, to each end of which a little cushion is fastened, which presses the cheeks forwards, when the instrument is put round the back part of the neck. To the middle of the steel a band is attached, which is smeared with adhesive plaster from the end of the instrument to the side of the wound. In the vicinity of the wound one end has a slit through which the other may be drawn. The rest may be applied in the manner of the common uniting bandage. (Louis, loco citato.) Others have the instrument made of whalebone, and fasten its two ends to some adhesive plaster, which is laid upon the cheeks. The whalebone is then made to push the sides of the face forward by means of a tape, which is fastened to the instrument, and the ends of which cross each other over the wound through a slit like the uniting bandage. (See Quesnay in Mémoires de l'Acad. de Chirurgie, tom. i.)

But Richter observes, that notwithstanding the foregoing arguments, the above bandages, and several others, which Platner, Chopart, &c. have recommended, are ineffectual without a suture. We should rather say that they are not so well adapted to practice as the twisted suture, because, in order to be successful, they require a great deal of trouble, and, after all, are not so certain of answering as the suture. Richter accounts for their inefficacy on the following principles: As the congenital hare-lip is a defect of first formation, he cannot see, with M. Louis, why this deformity of the lip should invariably be a mere division of the parts, without any loss of substance. He contends, that in some instances such a loss of substance is quite palpable, and that even when it does not originally exist, the surgeon must sometimes produce it in the operation, as, when he converts a double fissure into a single one, or when he removes a cancerous portion of the lip. The cleft in the bones of the palate is occasionally so considerable that nobody can entertain a doubt of there being in that situation an actual loss of substance. Richter inquires why the fissure in the lip should not be circumstanced in the same way? Were, says he, the object of uniting the wound the sole one in this case, perhaps the bandage would often answer; but as our aim is also to effect an exact union, and avoid all disfigurement; as the parts are here soft, yielding, very moveable, and frequently only a little supported, it is easily discernible that it must be exceedingly difficult to accomplish the intention with a bandage. The bandage has likewise the disadvantage of concealing the wound, so that the surgeon cannot see that things are in a proper position.

Perhaps not much weight ought to be assigned to the objection, that the pins inflame the wound, make it suppurate, and are apt to cut their way out. Extensive experience proclaims, that they have generally been employed with the happiest effect. Richter is of opinion, that where the pins have cut their way out, the uniting bandage would also have failed. Pins have been most successfully used for uniting the part, where the greatest part of the under-lip has been cut away. By the confession of its advocates, says Richter, the bandage has sometimes proved ineffectual. He maintains, that it ought not to be concluded, that a speedy union of the wound certainly cannot happen, because a degree of inflammation and suppuration has come on. The part may yet heal up without any deformity being left; only a little more time will be requisite.

The uniting bandage is subject to several disadvantages, which do not attend the employment of the twisted suture. In old persons, and children without teeth, the bandage never accomplishes an even union, as the lip in such cases

caſes receives no effectual ſupport. The bandage is ſtill leſs applicable, when there is a cleft in the upper jaw-bone as well as in the lip. Here the lip has a hollow underneath, and is preſſed inwards by the bandage into the fiſſure of the bone. This cannot happen without the edges of the wound being thrown out of their right poſition. In the double hare-lip, which muſt be operated upon at two different times, the bandage is not regularly effectual. After the operation for the firſt fiſſure, the bandage will not always ſerve to bring the lips of the wound into contact. It alſo happens, that when the edges of the wound are not cloſed as much internally as they are outwardly, the bleeding is apt to continue, and occaſion, eſpecially in infants, ſerious danger. Hence in making uſe of the bandage, we are not ſecure from the hazard of hæmorrhage; but in employing the twiſted ſuture, no riſk of this kind is encountered. Such bandages as paſs over the nape of the neck, or back of the head, eaſily ſlip out of their place, particularly in children, when they lie on their backs, and move or turn their heads to one ſide or the other. It is alſo very difficult to put on a bandage of this kind, with the proper degree of tightneſs, and conſequently, it is generally either too tight or too ſlack.

Richter refers to a caſe, in which, in conſequence of ſome trouble being experienced in bringing the edges of the wound properly together, the bandage was applied with tightneſs, ſo that the lip was preſſed in ſuch a way againſt the edge of the upper inciſor teeth, as to have a deep impreſſion made in it. When this accident was diſcovered, more than a half of the lip had been cut through. (See Richter's Obſervationum Chirurgicarum Faſciculus, 3.) With regard to the bandages which have been recommended, it is neceſſary to meaſure the dimenſions of the patient's head, and ſhould the ſurgeon make any blunder in this part of the buſineſs, the bandage will either not fit at all, or elſe very badly. In a word, ſays Richter, repeated experience proves, that the operation ſeldom fails with the twiſted ſuture, and that it frequently does ſo with a bandage, notwithſtanding the greateſt care and attention.

Adheſive plaſter alone is equally ineffectual, and, in ſome inſtances, totally uſeleſs. The ſtrips are apt to become quite looſe, when the ſaliva runs out of the mouth, after the operation has been performed upon the under lip. In adults who have ſtiff beards, the plaſter is every day puſhed off. The apparatus, propoſed by M. Valentin, (ſee Recherches Critiques ſur la Chirurgie Moderne), ſeems to be of itſelf, without the aid of other means, equally ineffectual. We need only ſay here, that it is a kind of forceps, with which the ſides of the wound are puſhed together. Richter objects to the inſtrument, that its preſſure is apt to bring on a painful ſwelling of the edges of the wound, notwithſtanding the precaution of covering the blades with ſome ſoft ſubſtance. An inconſiderable preſſure alſo will not ſuffice for keeping the ſides of the wound in contact, particularly when any difficulty is experienced in bringing them together; and in whatever manner the inſtrument is applied, there is no certainty of its fulfilling the object intended. The lip is ſaid to give way very frequently to the preſſure of the inſtrument, which, though it is at firſt ſufficiently tight, grows ſlack, and the edges of the wound become ſuppurated. In caſes in which the fiſſure extends high up into the noſtril, M. Valentin's inſtrument does not reach far enough, that is to ſay, it will not ſerve to keep the upper end of the wound cloſed, unleſs previous care be taken to detach the lip to the extent of a finger's-breadth on both ſides of the fiſſure, and upward to the noſe, from the gums and jaw-bone. Laſtly, Richter notices, that there are caſes where the fiſſure is ſo conſiderable, and ſo little of the lip is left after the neceſſary removal of a portion on each ſide, that there is ſcarcely room enough for the application of the inſtrument.

Upon the whole, the foregoing writer concludes, that bandages, adheſive plaſter, and other means of obtaining an union of the wound, propoſed by ſome of the moderns to be adopted after the operation for the hare-lip, are not ſuch as ought to be preferred, and that the ſuture is freer from objections than has been repreſented.

In a few favourable inſtances, perhaps, a bandage may by itſelf prove effectual; but Richter maintains, that it is always uncertain, and that the ſuture, in moſt caſes, ought not to be abandoned. The latter always anſwers in ſimple, eaſy caſes; and in thoſe which are attended with more difficulty, appear to be accompanied with a loſs of ſubſtance, do not admit the ſides of the wound to be brought into contact without trouble, and in which the patient is exceedingly reſtleſs and unmanageable, the ſurgeon may always aid the ſuture with other uniting means, a bandage and ſtrips of adheſive plaſter. But the bandage employed as an auxiliary to the ſuture, not only ought to preſs forward the cheeks, ſo as to keep the wound from gaping, and the pins from making their way through the fleſh; it ſhould, at the ſame time, be ſuch, as will not cover the whole of the wound, by which means the practitioner will retain the power of examining whether the edges of the diviſion are accurately in contact. The lip alſo ſhould not be preſſed by it againſt the teeth, ſo as to be rendered painful. The above-deſcribed bandages have not theſe properties. Richter thinks, that ſticking plaſter anſwers better, when applied in the following manner. Two large pieces of the plaſter are to be put upon the cheeks, and run forwards in a ſomewhat pointed way, terminating about half a finger's-breadth from the wound. To their anterior pointed ends, two or three threads are to be faſtened, which are to be tied in a ſlip-knot between the pins. In order to prevent the threads from preſſing againſt the wound, a bit of plaſter is to be put under them, or elſe a ſmall compreſs juſt under the front pointed end of the adheſive plaſters, ſo as to raiſe them up a little from the ſkin. Richter prefers the adheſive plaſter, thus uſed, to any ſort of bandage, and he conſidered it, in all caſes in which the pins require aid, by reaſon of the large ſize of the fiſſure, or the reſtleſſneſs and unmanageableneſs of the patient, as uſeful and neceſſary. In ſimple caſes, where the fiſſure is ſhort and narrow, the twiſted ſuture will anſwer every purpoſe of itſelf.

The little compreſſes, which ſome have propoſed to place under the pins on each ſide of the wound, are of no utility; they raiſe up the pins, tear and drag the wound, and either eaſily fall off, or ſlip out of their place.

In children, it is always proper, after the operation, to watch that the bleeding does not continue; for, as we have already detailed, the hæmorrhage is ſometimes kept up by ſuction of the wound, and is not readily perceived on account of the blood being ſwallowed. In order to hinder the child from being reſtleſs and crying, and thus diſturbing the dreſſings, it muſt be put to the breaſt whenever it awakes, and kept there till it falls aſleep again. Hence ſomebody muſt continually watch the little patient, it being uſual for children to begin crying when they wake and find themſelves alone. When an infant cannot be kept quiet in this manner, a little of the ſyrupus e meconio may every now and then be given to it.

Richter obſerves, that when, in conſequence of any incidental circumſtance, the dreſſings are diſturbed, and the wound made to gape, all hopes of a favourable termination of the caſe ſhould not be abandoned. He ſtates, that the wound, thus forced open again, has been often united with-

out

out any ill conſequences, as late, and even later than the eighth day.

As ſoon as the pins become looſe, which, according to the preceding author, uſually happens about the fifth or ſixth day, they ought to be withdrawn, and ſmall ſtrips of adheſive plaſter applied alone. Were the pins to be left in too long, they might occaſion ulceration, and leave ſuch ſcars behind as would never be effaced. It is ſcarcely neceſſary to remark, that the pins ought to be taken out with great gentleneſs, and the thread which is wound then firſt removed.

Sometimes there continues at the upper angle of the wound a ſmall foramen, through which the ſaliva oozes out. This in general ſoon heals on being touched with the argentum nitratum. When a fiſſure exiſts in the upper jaw and palate bones as well as in the lip, ſome recommend the cleft in the palate to be cloſed with ſome ſuch ſubſtance as a piece of ſponge, the front ſurface of which is covered with leather, or to cover the fiſſure in the bone with a bit of ſheet-lead, put under the lip, ſo as to ſupport the part and keep the wound from becoming too much depreſſed. Such a plan indeed may be really neceſſary, when either the uniting bandage alone, or the interrupted ſuture, is employed to heal the diviſion. But when pins are uſed for this purpoſe, their extremities lie cloſely to the edges of the fiſſure, ſo as to ſupport the lip, and render the foregoing means unneceſſary. This, ſays Richter, is one advantage attending the twiſted ſuture, as both the ſponge and lead preſs upon and irritate the wound.

The double hare-lip is operated upon in various ways. When the piece of fleſh ſituated betwixt the two fiſſures is long, broad, and ſoft, a particular operation is performed for each diviſion. As ſoon as one is completely well, the ſurgeon proceeds to the cure of the other. The ſurgeon muſt never attempt to operate upon both fiſſures at the ſame time; for if this method were purſued, the middle piece of fleſh would ſuffer ſo conſiderably from the many pins paſſed through it, and from being much ſtretched, that it would inflame exceſſively, and the deſign of the operation be fruſtrated.

When the knob of fleſh between the two fiſſures is ſhort, ſmall, and uſeleſs, it muſt be cut away with two ſtrokes of the knife, which are at the ſame time to remove the external edge of each fiſſure, thus convert both diviſions into one, and make them capable of being both removed by one operation. The laſt is the moſt frequent and favourable caſe. When two diſtinct operations are requiſite, the ſcars are generally more perceptible, and the patient ſuffers more pain. The middle portion of fleſh is ſeldom of any uſe, for the lips are ſo yielding, that there is commonly no reaſon to be apprehenſive about the loſs of ſubſtance.

It is ſaid, that hare-lips have been met with which were utterly incurable. Caſes have occurred in which the fiſſure was prodigiouſly large, its upper angle exceedingly wide, little of the upper lip to be ſeen on either ſide, that little hard and uſeleſs, adherent to the gums, and quite deformed, all which circumſtances are ſaid to have made the union of the fiſſure totally impracticable.

Children with a cleft in the bones of the palate, ſometimes have the upper jaw of preternatural breadth, ſometimes of the cuſtomary one. In the firſt caſe it may be conjectured, that there is a ſimple diviſion in the bone; in the ſecond an actual loſs of ſubſtance. When the infants, thus circumſtanced, cannot ſuck, an endeavour muſt be made to cloſe the fiſſure by means of an artificial palate. A bit of ſponge anſwers this purpoſe beſt, for when of proper ſhape, ſize, and thickneſs, and it is put in dry, it uſually keeps in its proper ſituation very well. It may be covered with leather upon the ſide towards the mouth, in order that it may not imbibe too much of the fluid which the child ſucks. The cleft in the palate is occaſionally ſo conſiderable, that the ſponge cannot be retained in it by any means whatſoever. In this kind of caſe, thin plates, provided with a ſpring, have been tried, though they ſeldom anſwer in an effectual way. Many infants can ſwallow fluids tolerably well, notwithſtanding the cleft in the palate, when ſuch fluids are given to them in a recumbent poſture. The liquid only eſcapes from the noſe in an upright poſition.

As ſoon as the hare-lip is cured, nature commonly cloſes the fiſſure in the bones of the palate, without any aſſiſtance from art. It is remarked, that this deſirable event never takes place before the operation for the hare-lip has been performed, a circumſtance which is urged in favour of undertaking it at an early period. (Levret, l'Art des Accouchemens, § 1321. La Faye Mem. de l'Acad. de Chirurgie de Paris, tom. 3. edit. 8. p. 201.) Several plans have been propoſed for promoting the cloſure of the fiſſure in the palate. Some have ſuggeſted introducing a piece of ſtring into the mouth, and tying it round one of the grinding teeth of the upper jaw on each ſide. (Jourdain, Journal de Médécine, tom. 39.) Such method is quite inapplicable to infants, without any grinding teeth; it would alſo be exceedingly inconvenient; and certainly, it is more likely to pull the teeth into an oblique direction, than to make the ſides of the bony fiſſure approximate each other. Others reſt ſome hope on the effect of a bandage, which will compreſs the ſides of the face together. (Levret, Journal de Médécine, tom. 37.) However, ſuch bandage, in all probability, would make the cheeks inflame, before it could have the leaſt effect in making the fiſſure in the bones at all narrower. Richter thinks more good would reſult from ſcarifying the ſides of the cleft, though he is of opinion that the beſt method to be followed, is to leave the union of the fiſſure in the bones to nature, and, if neceſſary, to adviſe the uſe of an artificial palate, until the communication between the mouth and noſe is cloſed.

Many of the preceding obſervations are to be found in Richter's Anfangſgrunde der Wundarzneykunſt. Band 2. Kap. 7.

HAREM, the quarter of the ſeraglio allotted to the women. See SERAGLIO.

HARENGIFORMES, in *Ichthyography*, a genus of fiſhes approaching to the herring in ſhape; the principal character of which is, a ſerrated line made up of ſcales running along the bottom of the belly; to which may be added, that the ſides and belly are of a bright ſilver colour, and that the ſcales are large and looſe.

HARENGUS. See CLUPEA *Harengus*.

HAREWOOD, in *Geography*, a pariſh and market-town in the upper diviſion of the wapentake of Skyraek, in the Weſt Riding of Yorkſhire, England. The town is about eight miles from Leeds, and 204 from London. In the year 1801, it contained 142 houſes and 707 inhabitants. The country around here abounds with woods, moſt of which belong to Harewood-houſe, the noble ſeat of lord Harewood. This manſion was built in 1708, and has two handſome architectural fronts. Harewood caſtle is an intereſting ſpecimen of caſtellated architecture. Soon after the Norman conqueſt it belonged to the family of Romily, from whom it deſcended to the Meſchines's. Mr. King aſcribes the preſent building to an age from Edward I. to Edward III. The remains ſtand on the north ſide of a triple ſquare entrenchment, on the brow of a hill. The embankments are high in ſome places, and the walls of two ſquare towers, a porch,

porch, and great hall are ſtill conſiderable. (Mr. King, in Archæologia, vol. vi. has given a ground plan, and a particular deſcription of this caſtle.) In the church are five curious ancient monuments, with effigies, &c. to the memories of the Rithers's and the Bedmans, who were lords of the caſtle; alſo of the Gaſcoigns of Gawthorp. One of this family, ſir William Gaſcoigne, committed Henry V. when prince of Wales, to priſon for affronting him whilſt he ſat in the judge's chair. He was chief juſtice in the reigns of Henry IV. and V.; and a fine monument with his ſtatue in alabaſter is preſerved in Harewood church.

HARFANG, in *Ornithology*. See STRIX *Nyctea*.

HARFLEUR, in *Geography*, a decayed town of France, in the department of the Seine, ſituated on the ſide of a hill, on a ſmall river near the Seine, the port of which has been ruined, ſo that the harbour is filled up and become fit only for boats, by the proſperity of Havre de Grace at the diſtance of four miles. The number of inhabitants is about 2400. N. lat. 49° 30'. E. long. 8° 27'.

HARFORD, a county of America, in Maryland, chiefly watered by Buſh river and Deer creek, on which are 16 mills. It contains 17,626 inhabitants, including 4264 ſlaves. Its chief town is Belle-Air.—Alſo, a poſt-town in the above-mentioned county, ſinking into decay, by the riſing importance of Belle-Air at the diſtance of nine miles, whither the courts of juſtice have been removed.

HARG, a ſea-port of Sweden, in the province of Upland; 30 miles N.E. of Upſal.

HARGHIAH, CAPE, a cape on the S. coaſt of Arabia. N. lat. 13° 30'. E. long. 47°.

HARGIA, a town of Arabia, in the province of Hadramaut, ſituated on the coaſt; 60 miles E.N.E. of Aden.

HARJAVALDA, a town of Sweden, in the government of Abo; 15 miles S.S.E. of Biorneborg.

HARIDI, a name given to a ſerpent at Achmim, in Upper Egypt, to which the artifice of the prieſts and the credulity of the people aſcribe many wonderful performances. The appellation is derived from that of a religious Turk, called "Scheick Haridi," who more than a century ago died at Achmim, and who was venerated as a ſaint, and actually worſhipped among the Mahometans, and to whoſe honour they raiſed a monument, covered with a cupola, at the foot of the adjacent mountain. One of their prieſts perſuaded his deluded votaries, that God had made the ſoul of the ſaint to paſs into the body of a ſerpent. He had taught one of the harmleſs animals of this ſpecies that abound in the Thebais to obey his voice, and by means of the ſerpent that attended him, he pretended to cure all diſorders, and he dazzled the vulgar by his ſurpriſing tricks. Having luckily practiſed in ſome inſtances with ſucceſs, he gained great celebrity. He ſoon confined his ſerpent Haridi to the tomb, producing him only to oblige princes, and perſons able liberally to recompence him. The ſucceſſors of this prieſt adopted his art; and they added to the general perſuaſion of his virtue, that of his immortality, and by an artful contrivance exhibited a public proof of it. The knavery of the prieſts has in this inſtance been highly lucrative. The people flock from all quarters to pray at this tomb; and if the ſerpent crawls out from under the ſtone, and approaches the ſuppliant, it is a ſign that his malady will be cured. We ſhall only add, that the ignorant and credulous Egyptians believe in the ſerpent Haridi, as firmly as in the prophet. And amongſt the dupes of a few impoſtors are ſome Chriſtians, who no more doubt the virtue of the ſerpent than the Turks; but the Chriſtians maintain that this ſerpent is the dæmon Aſmodeus, who ſlew the ſeven huſbands of Tobit's wife, brought by the angel Raphael to this place, after metamorphoſing him; and that God makes uſe of him to deceive the infidels. Savary's Letters, vol. i.

HARJEDALEN, a province of Sweden, in Nordland, incorporated with the Swediſh dominions in 1645, bounded on the N. by Jemptland, on the E. by Helſingland, on the S.W. by Dalecarlia, and on the N.W. by Norway; about 100 miles long, and from 40 to 50 broad: abounding in mines and woods, and poſſeſſing excellent paſtures, which ſupply a good home trade of horned cattle. Its rivers and lakes abound with fiſh. The inhabitants derive their ſubſiſtence from grazing, hunting, and fiſhing, and from the ſale of cheeſe, which is much eſteemed. Several places among the mountains are inhabited by Lappers.

HARIOT, or HERIOT, a due or ſervice, belonging to the lord at the death of his tenant: conſiſting of the beſt beaſt the tenant had at the time of his deceaſe.

Coke, on Littleton, obſerves, that *heriot* in Saxon is called *hereger*, q. d. the *lord's beaſt*; *here* ſignifying *lord*, and *gear*, *beaſt*; which others reject, urging that *here*, in Saxon, ſignifies an *army*; and *gear*, a *march*, or *expedition*; and that the Saxon *hereger*, whence we derive our *hariot*, ſignified *proviſion for war*, or a *tribute*, or *relief*, given to the lord of a manor, for his better preparation towards war. Spelman.

By the laws of Canutus, tit. De Heriotis, it appears that at the death of the great men of this nation, ſo many horſes and arms were to be paid, as they were in their reſpective life obliged to keep for the king's ſervice. The firſt eſtabliſhment, if not introduction, of compulſory hariots into England, was by the Danes. Upon the plan of this Daniſh eſtabliſhment, William the Conqueror faſhioned his plan of reliefs: when he aſcertained the preciſe relief to be taken of every tenant in chivalry, and, contrary to the feodal cuſtom and the uſage of his own duchy of Normandy, required arms and implements of war to be paid inſtead of money. (See RELIEF.) The Daniſh compulſive heriots, thus tranſmuted into reliefs, underwent the ſame viciſſitudes as the feodal tenures, and in ſocage eſtates frequently remain to this day in the ſhape of a double rent payable at the death of the tenant. The heriots which now continue amongſt us and retain the name, ſeem rather to be of Saxon parentage, and at firſt to have been merely diſcretionary. (Lamb. Peramb. of Kent, 492.)

HARIOT is of two ſorts: *viz. Hariot cuſtom*, where hariots have been paid time out of mind by cuſtom, after the death of a tenant for life: and they are defined to be a cuſtomary tribute of goods and chattels, payable to the lord of the fee on the deceaſe of the owner of the land.

Theſe heriots are now, for the moſt part, confined to copyhold tenures, and are due by cuſtom only, which is the life of all eſtates by copy; and perhaps are the only inſtances where cuſtom has favoured the lord. For this payment was originally a voluntary donation, or gratuitous legacy of the tenant: perhaps in acknowledgment of his having been raiſed a degree above villenage, when all his goods and chattels were quite at the mercy of the lord: and cuſtom, which has on the one hand confirmed the tenant's intereſt in exclu-ſion of the lord's will, has, on the other hand, eſtabliſhed this diſcretional piece of gratitude into a permanent duty. An heriot may alſo appertain to free land, that is held by ſervice and ſuit of court; in which caſe it is moſt commonly a copyhold enfranchiſed, whereupon the heriot is ſtill due by cuſtom. Bracton (l. 2. c. 36. § 9.) ſpeaks of heriots as frequently due on the death of both ſpecies of tenants: and he adds, "magis fit de gratia quam de jure;" in which Fleta (l. 3. c. 18.) and Britton (c. 69.) agree; thus plainly intimating the original of this cuſtom to have been merely voluntary,

voluntary, as a legacy from the tenant; though now the immemorial uſage has eſtabliſhed it as of right in the lord.

This heriot is ſometimes the beſt live beaſt, or "averium," which the tenant dies poſſeſſed of, (which is particularly denominated the villein's relief in the 29th law of king William the Conquêror,) ſometimes the beſt inanimate good, under which a jewel or piece of plate may be included: but it is always a *perſonal* chattel, which, immediately on the death of the tenant who was the owner of it, being aſcertained by the option of the lord (Hob. 60.), becomes veſted in him as his property; and is no charge upon the lands, but merely on the goods and chattels. The tenant muſt be the owner of it, elſe it cannot be due; and therefore on the death of a feme-covert no heriot can be taken; for ſhe can have no ownerſhip in things perſonal. (Keilw. 84. 4 Leon. 239.)

In ſome places there is a cuſtomary compoſition in money, as 10 or 20 ſhillings in lieu of a hariot, by which the lord and tenant are both bound, if it be an indiſputably ancient cuſtom; but a new compoſition of this ſort will not bind the repreſentatives of either party. Blackſt. Com. b. 2.

HARIOT *Service*, is when a tenant holds by ſuch ſervice to pay hariot at the time of his death; which ſervice is expreſſed in the deed of feoffment. This is due upon a ſpecial reſervation on a grant or leaſe of lands; and therefore amounts to little more than a mere rent. 2 Saund. 166.

For this latter the lord ſhall diſtrain as well as ſeize; and for the other he ſhall ſeize, and not diſtrain.

If the lord purchaſe part of the tenancy, hariot-ſervice is extinguiſhed; but it is not ſo of hariot-cuſtom.

HARIR, in *Geography*, a town of Nubia, on the right bank of the Nile; 25 miles E. of Dongola. N. lat. 19° 20'. E. long. 32° 34'.—Alſo, a town of Curdiſtan; nine miles E. of Erbil.

HARKO, a ſmall iſland of Sweden, in the N. part of the gulf of Bothnia. N. lat. 65° 27'. E. long. 24° 49'.

HARLE, in *Ornithology*, the name given by Buffon to the MERGUS tribe.

HARLECH, or HARDDLECH, in *Geography*, an inconſiderable market town in the pariſh of Llanvair, and hundred of Ardudwy, North Wales, England; was formerly the principal town in this part of the principality, and had a large caſtle. This, with the houſes, are ſeated on the brow of a cliff, which overhangs a flat marſh, on the ſea-coaſt, near Cardigan bay. The exterior walls of the caſtle are nearly entire, and aſſume a ſquare form of about 20 feet each way, with round towers at the angles, and at the entrance a fortreſs is ſaid to have been built on this ſcite by Maelgwn Gwynedd, prince of North Wales, about the year 530; but Edward I. erected the preſent edifice, which was finiſhed in the year 1283. The ambitious Owen Glyndwr ſeized and took poſſeſſion of it in 1404: but Henry IV. ſent an army into Wales ſoon afterwards, and diſlodged that chieftain. In 1460 it became the place of refuge and ſecurity to Margaret of Anjou, who fled here for protection after the diſaſtrous battle of Northampton, when Henry VI. was defeated. In the ſanguinary wars between the houſes of York and Lancaſter, this fortreſs was obſtinately defended by Dafydd ap Eſan ap Einion, on the part of the latter party. An army under the command of the earl of Pembroke at length compelled him to ſurrender it in 1468. In the civil wars between king Charles I. and the parliament, this caſtle was the laſt in Wales that was held in behalf of the monarch. Since that period it has gradually been mouldering to ruins, and though its architectural forms may ſtill be traced, its interior arrangement and fittings up are nearly obliterated. Beſides the caſtle Harlech does not contain any building or object of intereſt: but the ſcenery and antiquities of the environs are grand, curious, and worthy of the traveller's particular attention and enquiry. In the year 1692 an ancient golden torquis was dug up near the caſtle, and was committed to the care of ſir Roger Moſtyn. Several Roman coins have been found in and near the town. About five miles from Harlech, near the road to Barmouth, are two cromlechs near each other, and placed in the midſt of two carnedds. In the way to Maenturog are two concentric circles, ſome upright ſtones, and other objects of druidical antiquity. A tumulus and carnedd, larger than the reſt, is diſtinguiſhed by the title of king Arthur's tomb. Among the mountains is another large cromlech called Coeton-Arthur. For further particulars reſpecting Harlech and its environs, the reader is referred to Pennant's, Bingley's, Wyndham's, Evans', and Warner's reſpective Tours in Wales.

HARLED, in *Rural Economy*, a term ſignifying mottled or ſpeckled, as applied to neat cattle. It alſo implies a wall daſhed with lime and ſand or other ſimilar materials.

HARLEIAN *Collection of Manuſcripts*, is a valuable collection begun near the end of the laſt century, by Robert Harley, eſq. afterwards earl of Oxford, and increaſed in the year 1721 to near 6000 books, 14,000 original charters, and 500 rolls. This collection was farther enlarged by his ſon, and amounted at his death, in 1741, to 8000 volumes, and above 40,000 original rolls, charters, letters patents, grants, and other deeds and inſtruments of great antiquity. By ſtat. 26 Geo. II. it was enacted, that this collection ſhould be purchaſed for the ſum of 10,000*l*, and placed and continued in the ſame repoſitory with the Cottonian library. See *Britiſh* MUSEUM.

HARLEM, in *Geography*. See HAERLEM.

HARLEM, a townſhip of America, in Kennebeck county, Maine, incorporated in 1796, containing 262 inhabitants; 213 miles N.E. by N. from Boſton.—Alſo, a diviſion of New York county, in the northern part of York iſland, which, in 1790, contained 803 inhabitants.

HARLEQUIN, in the *Italian Comedy*, a buffoon dreſſed in party-coloured cloaths, anſwering much the ſame purpoſe as a merry-andrew, or jack-pudding, in our drolls, on mountebanks, ſtages, &c. We have alſo introduced the harlequin upon our theatres; and this is one of the ſtanding characters in the modern groteſque or pantomime entertainment.

The term took its riſe from a famous Italian comedian, who came to Paris under Henry III. and who frequenting the houſe of M. de Harley, his companions uſed to call him *Harlequino*, q. d. *little Harley*; a name which has deſcended to all thoſe of the ſame rank and profeſſion.

HARLESTON, in *Geography*, a market town in the pariſh of Redenhall and hundred of Earſham, county of Norfolk, England; is ſituated on the banks of the river Waveney. The church of Redenhall conſiſts of a chancel, nave, and two aiſles; and was rebuilt at the beginning of the 14th century. The tower, which is ſquare, and crowned with battlements, having a ſmall ſpire at each angle, and a larger in the centre, was begun in the year 1460, and finiſhed in 1520. In 1616 it was rent from top to bottom by lightning, and was anchored up as it appears at preſent. In 1680 the ſpire was entirely deſtroyed by a ſimilar accident, but was rebuilt the following year. Harleſton is 99 miles diſtant from London; has a weekly market on Wedneſdays, and two annual fairs, which are well frequented; particularly one held on the feſtival of St. John the Baptiſt, and continuing ſeven days; to which immenſe droves of Scotch cattle are brought. The return to parliament, in 1810, ſtated the town to contain 273 houſes and 1459 inhabitants. Blomefield's Hiſtory and Antiquities of Norfolk.

HARLEY, ROBERT, in *Biography*, earl of Oxford and

and Mortimer, eldeſt ſon of ſir Edward Harley, was born in the year 1661. At the period of the revolution, he and his father raiſed a troop of horſe at their own expence, and after the acceſſion of William and Mary he obtained a ſeat in parliament. In 1702 he was elected ſpeaker of the houſe of commons, and in 1704 he was ſworn of queen Anne's privy council, and one of the ſecretaries of ſtate. He was alſo one of the commiſſioners for the treaty of Union, and in 1710 was appointed chancellor and under-treaſurer of the exchequer. A ſingular incident occurred at this time, which tended to raiſe Mr. Harley into popularity. A perſon, calling himſelf the marquis de Guiſcard, a Frenchman, who had been refuſed a penſion by Mr. Harley, was apprehended on the charge of a treaſonable correſpondence with France: while under examination before the council board, he made a ſudden and deſperate attempt to ſtab him in the breaſt. Fortunately the knife, lighting on the bone, broke ſhort, without effecting much injury. Guiſcard was ſecured after much reſiſtance, and died ſhortly after in priſon. On this occaſion, an act was paſſed to make any attempt on the life of a privy counſellor felony; and both houſes of parliament joined in an addreſs to the queen, expreſſing "their deep concern for the attempt againſt the life of Mr. Harley, whoſe fidelity to her majeſty and zeal for her ſervice had drawn upon him the hatred of all the abettors of popery and faction." Mr. Harley was now raiſed to the dignity of lord high treaſurer, and created earl of Oxford and earl of Mortimer, two of the nobleſt titles in the Britiſh peerage. On the acceſſion of George I. the meaſures of the earl of Oxford were not purſued, and his enemies gaining the aſcendancy, he was impeached of high treaſon, and committed to the Tower, where he remained a cloſe priſoner two years. He now demanded a trial, and the lords and commons not agreeing in their plans for conducting the proceeding, was acquitted. He died in the month of May 1724: his political character has been variouſly repreſented; but it cannot be denied that he was an encourager of literature, and the greateſt collector in his time of curious books and MSS., his collection of which is now in the Britiſh Muſeum, and fills a large department of it. Smollet's Hiſt. of Engl.

HARLING, East, or *Market-Harling*, in *Geography*, is a market town and pariſh in the hundred of Guiltcroſs, and county of Norfolk, England.

The church, a handſome uniform building, conſiſts of a nave, two aiſles, a chancel, and a quadrangular tower, with a baluſtraded parapet wall ſurmounted by a ſmall ſpire. In a private chapel, originally connected with the manor, are various monuments for the Harling family; under an altar tomb are the remains of ſir Robert Harling, who was a diſtinguiſhed warrior in the time of king Henry V. and fell while bravely defending the city of Paris in 1435. In the windows are numerous figures and armorial bearings on ſtained glaſs. The glaſs in the chancel window formerly belonged to Harling-hall. This manſion was erected by ſir Thomas Lovell about 1500, but has been long ſince dilapidated. Harling was formerly celebrated for the manufacture and ſale of linen, yarn, and cloth; but its trade has greatly declined. A weekly market and two annual fairs are held under a charter granted by king Edward IV. The number of inhabitants, in the year 1706, was 401: but in 1801, the town was returned as containing 93 houſes, and 674 perſons. Harling is diſtant from London 93 miles. Blomefield's Hiſtory and Antiquities of Norfolk.

HARLINGEN, a ſea-port town of Holland, in the ſtate of Frieſland, on the Zuyder ſea. This place is well fortified and naturally ſtrong; the adjacent country being eaſily inundated. The city is ſquare, the ſtreets are ſtraight and clean, with canals in the middle of them. It has five gates, four towards the land, and one towards the ſea. The accumulation of ſand near the mouth of the harbour, which is large and much frequented, incommodes it, ſo that heavy veſſels are obliged to lie at a diſtance, or to diſcharge part of their load. The chief trade conſiſts in ſail-making, and alſo in importing and exporting corn, pitch, tar, fir-trees, and deals. The adjacent country is fertile, and affords abundant ſupplies of corn, paſture, and other neceſſaries of life. N. lat. 53° 11'. E. long. 5° 22'.

HARLOT, a woman given to incontinency; or that makes a habit, or trade, of proſtituting her body. See Courtesan.

The word is ſuppoſed to be uſed for the diminutive *whorelet*, a *little whore*. Others derive it from *Arlotta*, miſtreſs to Robert duke of Normandy, and mother to William the Conqueror. Camden derives it from one *Arlotha*, concubine to William the Conqueror: others from the Italian *arlotta*, a *proud whore*.

HARLOW, in *Geography*, is a pariſh and village in the hundred of the ſame name, in the county of Eſſex, England. It was formerly a market town and a place of conſiderable trade, but the market having fallen into diſuſe and the trade removed, the inhabitants are now chiefly ſupported by ſpinning and agricultural employments. But ſome advantages are derived from three annual fairs; particularly one, well known by the name of Harlow-Buſh Fair, which is held Sept. 9. on a common two miles from the town, for the ſale of horſes, cattle, &c. The church was partly demoliſhed by fire in 1711, but was ſoon reſtored, and ornamented with much painted glaſs. The original ſtructure was in the cathedral form; but the tower, which roſe from the centre, has been replaced by a cupola. Harlow is 23 miles diſtant from London; and, in the year 1801, contained 265 houſes, and 1514 inhabitants. About three miles diſtant, in the pariſh of Latton, are the remains of an Auguſtine priory, founded previous to the year 1270. Morant's Hiſtory and Antiquities of Eſſex, 2 vols. fol.

HARMA, a town of Sweden, in Eaſt Bothnia; 38 miles E.N.E. of Waſa,

HARMALA, in *Botany*, ἅρμαλα, an eminent Greek name, mentioned by Dioſcorides as a ſynonym of his Πηγανον, or Wild Rue. Tournefort retained it as a generic name, Inſt. 257. t. 133. but Linnæus preferred the latter. See Peganum.

HARMANGER, in *Geography*, a town of Sweden, in Helſingland; 12 miles N. of Hudwickſwall.

HARMATIAN, or Chariot Air, compoſed by the firſt Phrygian Olympus. According to Heſychius this air had the title of Ἁρμάτιος νόμος, from its imitating the rapid motion of a *chariot wheel*; or, from its fire and ſpirit, being proper to animate the horſes that draw the chariot, during battle.

HARMATTAN, a name given by the Fantees, a nation on the Gold Coaſt, to a ſingular wind that blows from the interior parts of Africa to the Atlantic ocean, on that part of the coaſt which lies between Cape Verd (N. lat. 15) and cape Lopez (S. lat. 1), ſometimes for a few hours, ſometimes for ſeveral days without regular periods. It is always attended with a fog or haze, ſo denſe as to render thoſe objects inviſible that are at the diſtance of a quarter of a mile: the ſun appears through it only about noon, and then of a dilute red, and very minute particles ſubſide from the miſty air, ſo as to make the graſs, and the ſkins of negroes appear whitiſh. The extreme dryneſs which attends this wind or fog, without dews, withers and quite dries the leaves of vegetables; and is ſaid by Dr. Lind at ſome ſeaſons

ſeaſons to be malignant and fatal to mankind; probably after much preceding wet, when it may become loaded with the exhalations from putrid marſhes; at other ſeaſons it is ſaid to check epidemic diſeaſes, to cure fluxes, and to heal ulcers and cutaneous eruptions; which is probably effected by its yielding no moiſture to the mouths of the external abſorbent veſſels, by which the action of the other branches of the abſorbent ſyſtem is increaſed to ſupply the deficiency. The uſual evaporation at Whidah is 64 inches; but when the Harmattan blows, it is at the rate of 133. Phil. Tranſ. vol. lxxi. See alſo Phil. Tranſ. vol. liii. p. 63. In many circumſtances, this wind ſeems much to reſemble the dry fog which covered moſt parts of Europe for many weeks in the ſummer of 1780, which has been ſuppoſed to have had a volcanic origin, as it ſucceeded the violent eruption of mount Hecla, and its neighbourhood. From the ſubſidence of a white powder, it ſeems probable that the Harmattan has a ſimilar origin, from the unexplored mountains of Africa. Nor is it improbable that the epidemic coughs, which occaſionally traverſe immenſe tracts of country, may be the products of volcanic eruptions; nor impoſſible, (ſays Dr. Darwin) that at ſome future time contagious miaſmata may be thus emitted from ſubterraneous furnaces in ſuch abundance as to contaminate the whole atmoſphere and depopulate the earth! Darwin's Botanic Garden, vol. ii. p. 219. note.

HARMER, Thomas, in *Biography*, was born at Norwich in 1715. He received the elements of claſſical learning in the country, and diſcovering an inclination for the profeſſion of a diſſenting miniſter, was ſent to London to purſue his academical ſtudies under the tuition of the learned Mr. Eames. When he had finiſhed his ſtudies, he ſettled with a ſmall congregation at Wattsfield, in Suffolk, where he devoted a conſiderable part of his time to the perfecting of his acquaintance with the Latin, Greek and Hebrew languages, in each of which he acquired much critical ſkill. The favourite object of his purſuit was the oriental knowledge, which he applied to the illuſtration of the ſacred writings. Obſerving a ſtriking conformity between the preſent cuſtoms of the eaſtern nations, and thoſe of the ancients, as mentioned or alluded to in various paſſages of ſcripture, he conceived a deſign, at a very early period, of making extracts of ſuch paſſages in books of travels and voyages, as appeared to him to furniſh a key to many parts of holy writ. In the year 1764 he publiſhed a volume of "Obſervations on divers Paſſages of Scripture, &c." The favourable reception which this work met with, encouraged Mr Harmer to proceed in it, and in 1776 he gave the public an enlarged edition of it, in two vols. octavo. In the preface to this impreſſion, after acknowledging the various helps he had received in the progreſs of his undertaking, he ſays, "But the greateſt advantage to this edition are thoſe additions of all the various kinds I have been mentioning, which have been furniſhed by ſome MS. papers of the late ſir John Chardin, who reſided long in the Eaſt, was a curious obſerver, and paid particular attention to ſuch matters as might ſerve to illuſtrate paſſages of Holy Writ, which led him to make many obſervations very much reſembling thoſe that were heretofore publiſhed in this work." With theſe papers he was furniſhed by Dr. Lowth, biſhop of London, who honoured him with a correſpondence on the ſubject, and probably by his example, Mr. Harmer was encouraged by perſons of the higheſt rank in the eſtabliſhed church. Animated with their approbation, he proceeded to collect two other volumes, which he publiſhed in the year 1787. Mr. Harmer, having thus rendered his work as complete as he intended, ſeemed happy and ſatisfied that his exertions could not but be of great utility to the biblical ſtudent, the divine, and the ſcholar; and in this deciſion every competent judge has agreed from that time to the preſent. Mr. Harmer died without a ſtruggle in November 1788, having paſſed the preceding day in perfect health. He was author of the "Outlines of a new Commentary on Solomon's Song, drawn by the help of Inſtructions from the Eaſt:" an "Account of the Jewiſh Doctrine of the Reſurrection of the Dead," and ſome other tracts of a leſs general nature. To the high merits of Mr. Harmer, profeſſor Symonds of Cambridge has borne a moſt ample teſtimony, part of which we ſhall tranſcribe. His reputation as a ſcholar and a divine is fully and univerſally eſtabliſhed. He may ſometimes be thought inelegant in his ſtyle, and too minute in his facts, yet theſe defects are amply compenſated by the general choice of his materials, and the clearneſs of the method with which he digeſted and arranged them. Some books come into the world ſet off with all the ornaments of language, and, with their authors, are ſoon forgotten; they reſemble thoſe meteors which, by their luminous appearance, attract our notice, and almoſt in the ſame moment vaniſh from our ſight. The credit of Mr. Harmer's writings reſts upon a foundation ſtrong and durable; he hath profeſſedly treated a ſubject of the firſt importance, which had before been touched upon only incidentally, and by ſhewing at large the wonderful conformity between the ancient and modern cuſtoms of the Eaſt, hath not only thrown a conſiderable light upon numberleſs paſſages in the bible, but hath opened new and fruitful ſources for the uſe of future expoſitors. In ſpeaking of our author in another character, he ſays, he was governed by a general principle of benevolence, and though he was commonly called the father of the diſſenters, yet his good offices were ſo far from being confined to thoſe of his own communion, that he acknowledged and encouraged merit wherever he found it. "I will apply to Harmer, was the uſual language of every injured perſon in his neighbourhood, and it ſeldom happened that the aggreſſor was not ſoon induced, by his perſuaſion, to repair the injury which he had done; and I do not exaggerate when I affirm that there is not, probably, a ſingle inſtance of an individual to be found, who, by a mild and ſeaſonable interference, prevented more law-ſuits than Mr. Harmer." See Symonds's Obſervations on the Expediency of reviſing the preſent Engliſh Verſion of the Goſpel.

HARMODIUS. Among the patriotic nomes or ſongs of the Athenians, there are none more frequently mentioned by ancient authors, than thoſe upon Harmodius and Ariſtogiton, who ſignalized their courage againſt Hipparchus and Hippias, the ſons and ſucceſſors of Piſiſtratus, king of Athens. Hipparchus having publicly inſulted the ſiſter of Harmodius, he, in conjunction with his friend Ariſtogiton, ſlew him at the Panatheneæan games, which event was the ſignal to the natives of Athens for recovering their liberty. The following are fragments of popular ſongs in honour of Harmodius.

1ſt Fragment.

Cover'd with myrtle-wreaths I'll wear my ſword,
Like brave Harmodius, and his patriot friend
Ariſtogiton, who the laws reſtor'd,
The tyrant ſlew, and bade oppreſſion end.

2d Fragment.

Harmodius dear! thou art not dead,
Thy ſoul is to Elyſium fled;

Thy virtue there a place has won,
With Diomede, great Tydeus' ſon;
With ſwift Achilles, too, thou art join'd,
And ev'ry friend of human kind.

See ARISTOGITON.

HARMONIA, Αρμονια, in *Anatomy*, a ſort of juncture or articulation of the bones.

Harmonia is a ſpecies of the *ſynarthroſis*, or juncture intended for abſolute reſt.

Two bones are ſaid to be joined *per harmoniam*, by harmonia, when the juncture is in one uniform, right, or circular line; or when the bones meet with even margins; in contradiſtinction from *ſutura*, where they are indented.

The bones of the upper jaw, and moſt of the epiphyſes, are joined *per harmoniam*.

HARMONIA, Lat. *Harmony*, in *Muſic*, the coincidence, or agreeable uniſon or mixture of two or more notes or ſounds.

HARMONIA, in *Mythology*, the wife of Cadmus. See CADMUS.

HARMONIÆ, in *Muſic*, an interval which, according to M. Henfling, has a ratio of $\frac{1}{1}\frac{2}{2}\frac{5}{8}$, $= 21\,\Sigma + 2\,m$, and is the *Enharmonic* DIESIS, which ſee.

HARMONICA, a term given by the ancients to that part of muſic, which conſiders the ratio or proportion of ſound to ſound. See HARMONICS.

HARMONICA *Regula*. (See MONOCHORD.) That excellent organiſt and worthy man, the late Mr. Keeble, coadjutor with Roſeingrave, as organiſt of St. George's, Hanover ſquare, bewildered himſelf many years in the ſtudy of the harmonica.

He does not ſeem, however, to have diſcovered with all his long and intenſe ſtudy, what others have clearly demonſtrated; that by *harmony* the ancients mean preciſely what the moderns imply by *melody*. The late Mr. Maſon, who being a good muſician, *alla moderna*, and, probably, much better acquainted with Greek literature than Mr. Keeble, has defined the harmony of the ancients in the following manner.

Muſical Definitions.

Harmony of the Ancients.

The ſucceſſion of ſimple ſounds, according to their ſcale, with reſpect to acuteneſs or gravity.

Melody.

The ſucceſſion of theſe harmonical ſounds, according to the laws of rhythm or metre; or, in other words, according to time, meaſure, and cadence.

Harmony of the Moderns.

The ſucceſſion of combined ſounds or chords, according to the laws of counterpoint.

Melody,

What the ancients meant by harmony; rhythm and metre being excluded.

Air,

What the ancients underſtood by melody.

According to theſe definitions, it appears that harmony, as we call it, was unknown to the ancients; that they uſed that term as we uſe ſimple melody, when we ſpeak of it as a thing diſtinguiſhed from modulated air; and that their term melody was applied to what we call air or ſong. If this be true, much of the difficulty in underſtanding ancient muſical writers will vaniſh.

"If an ancient Tibicen uſed an improper tone or ſemi-tone, or tranſgreſſed the rule of the mode or key in which he was playing, he committed an error in harmony, yet his melody might have been perfect with reſpect to the laws of rhythm and meaſure. We ſhould rather ſay of a modern muſician, in the ſame inſtance, that "he ſung or played wrong notes, or was out of tune, yet kept his time." Whoever made this diſtinction, would have been allowed by the ancients to poſſeſs a good harmonical ear, though the moderns would call it an ear for melody or intonation. We put this familiar inſtance only to make the difference of the definitions more clear."

We ſhould call an inſtrument out of tune inharmonious, though the intervals are nearly right.

By harmony and harmonics, the Greeks implied nothing more than that proportion of ſound to ſound which mathematicians term ratio, or, in common language, muſical tones that ſucceed each other agreeably. As ancient harmony was the ſucceſſion of ſingle ſounds, modern harmony is the ſucceſſion of chords.

Whether the diatonic ſcale was originally the work of nature or art, we ſhall not here attempt to convince our readers: but in Europe, it is now what every infant hears in the nurſery, and afterwards in the church and the ſtreet, ſo conſtantly, that a pſalm-tune or ballad, ſung in ſuch ſtrange ſcales or genera as Mr. Keeble recommends to our ſtudy and revival, would give an uneaſy ſenſation to the moſt ignorant clown in a country village, to whom nature has given a diſcriminating ear. By a great parade of Greek terms and ratios, Mr. Keeble has rendered what good writers had made tolerably plain and intelligible to common ſenſe and common readers, obſcure, repulſive, and unintelligible. All theſe are modern ideas, and indeed the whole book is built on modern principles, with ancient names and technica, all things are taken for granted, and nothing proved by citations from ancient authors.

By the harmonica, the ſubject of the late Mr. Keeble's book, is meant nothing more than the ratio of muſical ſounds, *a la Grec*, as Dr. Smith's harmonics is that of the moderns. Mr. Keeble, among all his boaſts of diſcoveries in ancient muſic, which had eluded all the inquiries and calculations of the greateſt philoſophers and mathematicians, has revealed nothing uſeful to modern muſic, or luminous concerning the ancient. The ſection of the harmonical canon, or diviſion of the monochord, according to Euclid, has ſo often been treated by modern theoriſts, from Galileo's time to the preſent, without improving compoſition or aſſiſting the practical ſtudent upon any inſtrument. As a matter of ſpeculation, and from an ambition of paſſing for men of ſcience, few muſicians write on the elements of their art without a parade of ratios, which they copy out of other books, without being able to judge of their accuracy, or to explain them to their readers. Even the profound Dr. Pepuſch was obliged to get Demoivre and G. Lewis Scot to calculate for him, who laughed at his pretenſions to mathematical knowledge, when he delivered his paper on the genera of the Greeks to the Royal Society. See VIBRATIONS, SONS HARMONIQUES, PYTHAGORUS, and EUCLID.

HARMONIC ELEMENTS, or *Concordant Elements*, are the minor third, (3d,) whoſe ratio is $\frac{5}{6}$, $= 161\,\Sigma + 3f + 14\,m$ the major third (IIId) whoſe ratio is $\frac{4}{5}$, $= 197\,\Sigma + 4f + 17\,m$, and the minor fourth (4th), whoſe ratio is $\frac{3}{4}$, $= 254\,\Sigma + 5f + 22\,m$: ſince each one of theſe ſingly is harmonious

or concord, and every addition of them in pairs is the ſame as 3d + III = V, the fifth; 3d + 4th = 6th, the minor ſixth; and III + 4th = VI, the major ſixth; while the ſum of theſe three elements, or 3d + III + 4th = VIII, the octave, is ſo perfect a concord, that it may be added any number of times to itſelf, or to each of the ſix other concords above named, and ſtill produce concords: and what confirms the character of theſe as the concordant elements is, that there are no other accords of two ſounds which are agreeable to the ear than thoſe produced as above, as will be plain from col. 2. of the table in our article CONCORD.

HARMONIC *Genus*. The ancients often gave this title to the genus commonly ſtyled the *Enharmonic Genus*. See ENHARMONIC.

HARMONIC *Sliders*, are a contrivance by Dr. Thomas Young, lecturer at the Royal Inſtitution, and deſcribed in its "Journal," (as alſo in Nicholſon's Journal, 8vo. iv. p. 101), for explaining his ideas of the coaleſcence of ſounds, and the combinations of motion which take place in various caſes of the junction of undulations, as of the tides of the ocean, &c. Theſe harmonic ſliders conſiſt of a great number of ſhort rods of wood, of the ſame breadth and thickneſs, but of different lengths, ſliding eaſily ſide by ſide in a long mortice, in a piece of wood, having a thumb-ſcrew at its end for clamping or fixing all the ſliders faſt, on occaſion: the lengths of the ſeveral ſliders in each of the ſeveral mortice frames, are adapted to the ordinates of ſeveral regular undulating curves, like the figure of ſines almoſt. A number of ſolid pieces of wood are wrought on the top into planes, having ſimilar undulating curves: and by placing the ſliders on theſe curves, and looſening the thumb-ſcrew, ſo that every ſlider may reſt on the curve below, the tops of theſe ſliders form a new curve, exhibiting the ſum of the ordinates of the curves to which the ſliders are cut, and the wood on which they reſt, above the plane of its bottom.

By making the fixed ſurface terminate in a ſeries of ſimilar curves, that bear to thoſe of the ſliding ſurface, the ratio of two muſical ſounds, and ſuch ratio but ſmall: "the phenomenon of the *beating* of an imperfect uniſon in muſic may be imitated, where the joint undulation becomes alternately redoubled and evaneſcent." A figure is given, in which "the proportion is that of 17 to 18, and the curvilinear outline repreſents the progreſs of the joint ſound, from the greateſt degree of intenſity to the leaſt." The ratio here given $\frac{17}{18}$ is equal in Mr. Farey's Notation to 50.46033 Σ $+ f + 4m$, being but a trifle leſs than the half-tone of the equal temperament ſcale, and therefore as ill adapted to repreſent an imperfect *uniſon*, as the figure alluded to is to convey an idea of a beating uniſon, or, indeed, that of any other conſonance; and we are ſomewhat ſurpriſed, that Mr. John Gough, who ſo ably and ſucceſsfully combated the doctor's theory, of which this is a branch, in this and the preceding volume of Mr. Nicholſon's Journal, did not animadvert on the very extraordinary aſſumptions made in this account of the harmonical ſliders.

HARMONICAL, belonging to harmony, as harmonical diviſions of the monochord, harmonical proportion, harmonical canon, &c.

HARMONICAL *Arithmetic*, is ſo much of the theory and doctrine of numbers as relates to making the compariſons, reductions, &c. of muſical intervals, which are expreſſed by numbers, in order to our finding their mutual relations, compoſitions, and reſolutions.

HARMONICAL *Compoſition*, in its general ſenſe, includes the compoſition both of harmony and melody; *i. e.* of muſic, or ſongs, both in a ſingle part, and in ſeveral parts.

In its more proper and limited ſenſe, harmonical compoſition is reſtrained to that of harmony. In which ſenſe it may be defined, the art of diſpoſing and concerting ſeveral ſingle parts together, in ſuch manner as to make one agreeable whole.

The art of harmony has been long known under the name of *counterpoint*.

At the time when parts were firſt introduced, muſic being then very ſimple, there were no different notes of time; and the parts were in every note made concord.

This they afterwards made *ſimple*, or *plain counterpoint*, to diſtinguiſh it from another kind, then introduced, wherein notes of different value were introduced, and diſcords brought in between the parts.

This they called *figurative counterpoint*.

HARMONICAL *Curve*, a curve, the nature of which will be underſtood from its conſtruction. Let C (*Plate* IX. *Analyſis*, *fig.* 4.) be the common centre of any two circles D F, E G, and C D E, C F G, any two ſemidiameters, and of either of the included arcs, as D F, let F H be the ſine, in which, produced both ways, let the lines H I and H K be ſeverally equal to the other arc E G; then, while the ſemidiameter C F G moves round the centre C, and carries with it the line I F H K, parallel to itſelf, and conſtantly equal to twice the arc E G, the extremities I K will deſcribe a curve, whoſe vertex is D and axis D C, and whoſe baſe A C B is equal to the ſemicircumference of the circle E G.

Cor. 1.—Drawing F L (*fig.* 5.) perpendicular to the baſe A C L, a line K P, perpendicular to the curve at K, will be parallel to E L.

For drawing K N perpendicular to the baſe, let the radius C F G go forwards a little into the place C *f g*, and carry the line K H F I into the place *k h f i*, cutting K N in O and F L in *r*. Then ſince H K = E G by the definition, and alſo *h k* = E *g*, their difference O *k* is = G *g*. Now by the ſimilar triangles C L F and F *r f*, C F *f* and C G *g*, O K *k* and N P K, we have C L : C F :: F *r* : F *f*, and C F : C G :: F *f* : G *g*, and *ex æquo* C L : C G or C E :: (F *r* : G *g* :: O K : O *k* ::) N P : N K; conſequently the right-angled triangles C L E, N P K are equiangular, and the perpendicular K P M is parallel to the line E L.

Cor. 2.—At any point K the radius of curvature K M: L E :: L E^2 : K N × C E. For drawing *f l* parallel to F L, another line *k* M, perpendicular to the curve at *k*, will be parallel to E *l* (by Cor. 1.); conſequently, if the arc K *k* be infinitely diminiſhed, either of the coinciding perpendiculars K M, *k* M will be the radius of the curvature at K. In the line E *l* take E *s* = E L, and joining L *s*, the triangles I E *s* and K M *k*, C E L or C E *l* and *s* L *l*, are ultimately equiangular. Now K N or F L : L C :: *f r* : *r* F or K O, and L C : L E :: P N : P K :: K O : K *k*; and, *ex æquo*, K N : L E :: *f r* : K *k*. But C E : L E :: *s* L : L *l* or *f r*, therefore, *componendo*, K N × C E : L E^2 :: (*s* L : K *k* ::) L E : K M.

Cor. 3.—Hence if the ratio of the circles C E G, C D F be very great, the curvature at any point K will be extremely ſmall, and its radius K M : C E :: C E : K N very nearly; becauſe the lines L E and C E will be very nearly equal.

Cor. 4.—Upon the ſame ſuppoſition the very ſmall curvatures at any points D, K are very nearly in the ratio of their diſtances D C, K N from the baſe A B. For when C E, and conſequently A B is given, the curvature at K, being reciprocally as its radius K M, is directly as K N (by Cor. 3.)

Cor. 5.—While the greater circle (*fig.* 6.) remains, let the leſſer be diminiſhed, and the curve A K D B will be changed into another A *x* B of the ſame ſpecies, and every ordinate

to

to the common baſe will be diminiſhed in the ſame ratio, that is, N K : N $\varkappa$ :: C D : C δ. For while any arc E G (*fig.* 5.) equal to H K or C N is given in magnitude, let the other radius C D or C F be diminiſhed, and becauſe the triangle C F H retains its ſpecies, the line C H or N K is diminiſhed in the ſame ratio with C F or C D.

Cor. 6.—When the axes C D, C δ (*fig.* 6.) of two curves are very ſmall in compariſon to their common baſe A B, the curvatures at the tops of any two coincident ordinates N K, N $\varkappa$ are in the ratio of the ordinates. For if $\varkappa\mu$ be the radius of curvature at $\varkappa$, by Cor. 3. we have K M × K N = C E^2 = $\varkappa\mu \times \varkappa$ N; whence $\varkappa$ N : K N :: K M : $\varkappa\mu$, that is, as the curvature at $\varkappa$ to the curvature at K.

Cor. 7.—Hence, ſuppoſing the curve A K D B to have the elaſticity and tenſion of a muſical chord (ſee CHORD), it will vibrate to and fro in curves very nearly of the ſame ſpecies with the given curve A K D B, provided none of the vibrations be too large.

For let the firſt effort of the tenſion reduce that curve into ſome other, as A $\varkappa\delta$ B, in the firſt moment of time; and ſince the ordinates D C, K N are in proportion as the curvatures at D and K by Cor. 4, and thoſe curvatures as the accelerating forces at D and K, acting in the directions D C, K M or K N very nearly, and theſe forces as the velocities generated by them in that time, and the velocities as the naſcent ſpaces D δ, K $\varkappa$; we have, *alternando*, D C : D δ :: K N : K $\varkappa$, and, *dividendo*, D C : δ C :: K N : $\varkappa$ N. Conſequently by Cor. 5, the curve A $\varkappa\delta$ B is very nearly of the ſame ſpecies with A K D B. And in the next moment it will be changed into another of the ſame ſpecies, and ſo on till every point of the chord be reduced to the baſe A B at the ſame inſtant. And by the motion here acquired it will be carried towards the oppoſite ſide of the baſe, till by the oppoſition of the tenſion it ſhall loſe all its motion by the ſame degrees, and in the ſame curves, by which it was acquired; and thus the chord will continually vibrate in curves of the ſame ſpecies as the firſt, neglecting the ſmall differeece in the directions K N, K M, and the reſiſtance of the air.

Cor. 8.—The ſmall vibrations of a given muſical chord are iſochronous. For if the chord at the limit of its vibrations aſſumes the form of the harmonical curve, it will vibrate to and fro in curves of that ſpecies by Cor. 7, and its ſeveral particles being accelerated by forces conſtantly proportional to their diſtances from the baſe A B, will deſcribe thoſe unequal diſtances in equal times, like a pendulum moving in a cycloid. See CHORD.

If the chord at the limit of its vibration aſſumes any other form, it will cut an harmonical curve, equal in length to it, in one or more points, as A, K, L, B, (*fig.* 7.); and the intercepted parts of the chord will be more or leſs incurvated towards A B, than the correſponding parts of the curve, according as they fall without or within them; and will accordingly be accelerated by greater or ſmaller forces than thoſe of the correſponding parts of the curve: therefore, ſuppoſing the chord and curve to differ in nothing but their curvatures, the difference of the curvatures of the correſponding parts will be continually diminiſhed by the difference of their forces, till the parts coincide either before, or when they arrive at the baſe A B. And thus the time of the ſeveral vibrations of the chord will be the ſame as thoſe of the curve, and therefore equal to one another.

Cor. 9.—The figure, contained under the harmonical curve and its baſe, is of the ſame ſpecies as the figure of ſines. (See SINE.) For ſuppoſing the circle D F Q (*fig.* 5) to grow bigger, till it becomes equal to E G R, the figure A K D B will become a figure of ſines. Becauſe any ordinate K N to the abſciſs A N, or arc G R, being conſtantly equal to F L, will then be equal to the ſine of the arc G R; and thus every ordinate, as K N, is increaſed in the given ratio of C F to C G, or C D to C E. And, on the contrary, the ſeveral ordinates in the ſaid figure of ſines, diminiſhed in that conſtant ratio of C E to C D, are the ordinates in the figure A K D B of the harmonical curve. Hence it appears, that, as the ordinates are diminiſhed in a conſtant proportion, their increments and fluxions are diminiſhed in the ſame proportion, the fluxion of the baſe remaining conſtant.

Cor. 10.—The radius of curvature at the vertex of the harmonical curve, is to that of the figure of ſines, on the ſame baſe, as the greateſt ordinate of the figure of ſines to that of the harmonical curve. For taking any equal evaneſcent portions of the vertical tangents, the radii will be inverſely as the ſagittæ, which are ſimilar portions of the correſponding ordinates, and are therefore to each other in the ratio of thoſe ordinates.

Cor. 11.—The figure, of which the ordinates are the ſums of the correſponding ordinates of any two harmonical curves, on equal baſes, but croſſing the abſciſs at different points, is alſo an harmonical curve. The abſciſs of the one curve being x, that of the other will be $a + x$, and the ordinates will be b . (ſin. x) and c . (ſin. $a + x$); now ſin. $a + x$ = (cof. x) . (ſin. a) + (cof. a) . (ſin. x), and the joint ordinate will be ($b + c$.) (cof. a) . (ſin. x) + c . (ſin. a) . (cof. x); if, therefore, d be the angle, of which the tangent is $\frac{c \cdot (\text{ſin. } a)}{b + c \cdot (\text{cof. } a)}$, its ſine and coſine will be in the ratio of c . (ſin. a) to $b + c$ (cof. a), and (cof. d) . (ſin. x) + (ſin. d) . (cof. x), will be to the ordinate in the conſtant ratio of ſin. d to c . (ſin. a); but (cof. d) . (ſin. x) + (ſin. d) . (cof. x) is the ſine of $d + x$: conſequently the newly formed figure is an harmonical curve.

The ſame may be ſhewn geometrically, by placing two circles, having their diameters equal to the greateſt ordinates of the ſeparate curves, ſo as to interſect each other in an angle equal to twice the angular diſtance of the origin of the curves (ſee *fig.* 8): then a right line revolving round their interſection with an equable velocity, will have ſegments cut off by each circle, equal to the correſponding ordinate; and the ſum or difference of the ſegments will be the joint ordinates; and if a circle be deſcribed through the point of interſection, touching the common chord of the two circles, and having its radius equal to the diſtance of their centres, this circle will always cut off in the revolving line a portion equal to the ordinate. For if A B be made parallel to C D, and E B to F G, ∠ A B E = C G F = C H F; but E I B is a right angle as well as H C F, and E I : I B :: F C : C H :: A E : C H, ſince A F is equal to twice the diſtance of the centres, which biſect A H and F H, and therefore to C E, and F C = A E, or E I : A E :: I B : C H; but E I : A E :: I D : A C, therefore I B : C H :: I D : A C, and the triangles A C H, D I B are ſimilar, and ∠ D B I = C H A = D K A, and A D is a parallelogram, conſequently K D = A B = C G.

If the circle C G be ſuppoſed to revolve round C, the interſection H will always ſhew the angular diſtance of the point in which the curve croſſes the axis; and the diſtance of the centres will be equal to the greateſt ordinate. If, therefore, the circles are equal, the greateſt ordinate will alſo vary as the chord of an arc increaſing equally, or as the ordinate of the harmonical curve. Smith's Harmonics, Sect. XI. Young's Natural Philoſophy, &c. vol. ii. p. 25, &c.

HAR-

H A R

HARMONICAL *Interval.* See INTERVAL.

HARMONICAL *Proportion.* See *Harmonical* PROPORTION.

HARMONICAL *Series*, is a ſeries of many numbers in continual harmonical proportion.

If there be four or more numbers, whereof every three immediate terms are harmonical, the whole makes an harmonical ſeries, of continual harmonical proportionals; as, 30: 20: 15: 12: 10.

Or if every four immediately next each other are harmonical, it is alſo a continual harmonical ſeries, but of another ſpecies; as, 3, 4, 6, 9, 18, 36, &c.

HARMONICAL *Sounds*, or *Sons Harmoniques.* See SON and SOUND.

HARMONICS. All the concomitant or acceſſary *ſounds*, which, on the principle of reſonance, accompany every ſingle ſound, and render it perceptible, are thus called. And thus all the aliquot parts of a ſtring produce harmonics. This ſubſtantive is maſculine when *ſound* is underſtood; and feminine when the word chord, or ſtring, is in queſtion.

HARMONICS, *Experiments in.* See NOTE-FLUTEE. The effects of different tunings, beats of uniſons and octaves on the violin, all the ſtrings ſtruck at once on the guitar, and monochord tuned and divided harmonically, ſeem a uniſon, like a ſingle key on the full organ.

The term Harmonics generally implies the theory of ſound; the diviſion of the monochord into harmonic intervals, by menſuration, or ratios, including concords, diſcords, and temperament.

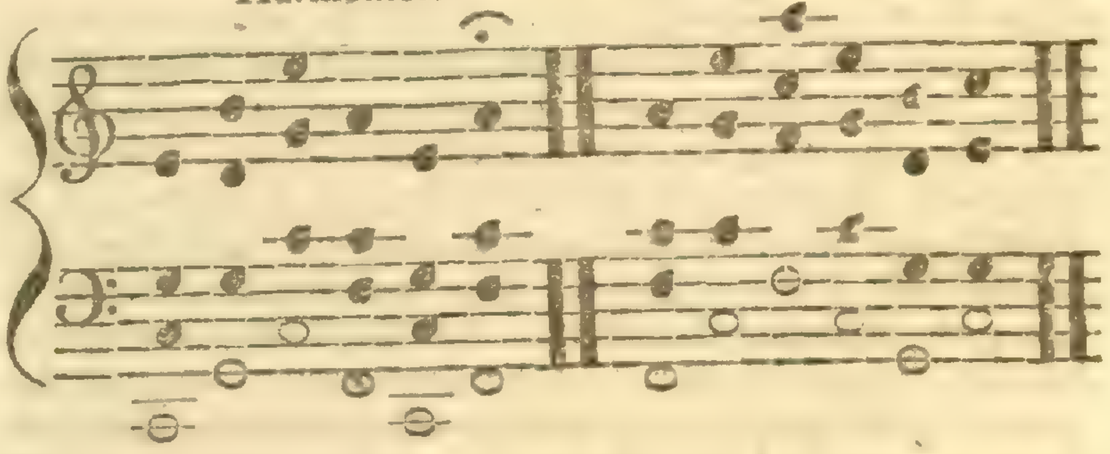
But the harmonics of which we have now to ſpeak, are the ſounds generated by a ſingle grave tone, either of a great bell, or ſtring of an inſtrument. Small bells and ſtrings have doubtleſs their harmonics; but they are too acute for our perception and appreciation.

It is now well known, that any ſingle deep muſical tone, ſuch as the 3d or 4th ſtring of a violoncello, ſoon after it is cauſed to ſound, produces, beſides the tone of the whole ſtring, its octave, 12th, 15th, 17th, 19th, and faintly, the 21ſt, which, by contraction, for the convenience of our hands on keyed-inſtruments, we form into a common chord, or 3d, 5th, and 8th, the moſt pleaſing combination of muſical ſounds in our ſyſtem of harmony. By nice obſervation it was diſcovered in the 17th century, by Galileo, that a ſtring, when cauſed to vibrate by a quill, a hammer, or a bow, divided itſelf into all the above proportions, by a kind of magic knots or bridges: that half the ſtring produced the octave of the whole; the 3d part of the ſtring, the 5th of the octave; the 4th part, the double octave of the whole; the 5th part, the 17th, or major 3d to the double octave; the 6th part, the double octave of the 5th, or minor 3d to the 17th, or major 3d; the 7th part of the ſtring, when we hear it ſound, is the flat 7th to the double octave of the whole ſtring. Mathematicians expreſs theſe proportions by ratios, thus: acute, $\frac{1}{1}$, $\frac{2}{1}$, $\frac{3}{2}$, $\frac{4}{3}$, $\frac{5}{4}$, $\frac{6}{5}$: grave, $\frac{1}{1}$, $\frac{1}{2}$, $\frac{2}{3}$, $\frac{3}{4}$, $\frac{4}{5}$, $\frac{5}{6}$.

And by theſe figures are expreſſed, not only the ſeveral diviſions of the ſtring, or monochord into harmonical proportions, but the proportional number of vibrations which each of theſe ſeveral conſonances makes, compared with the reſt.

If we produce a deep tone from a great bell, or the 4th ſtring of a violoncello, we hear, beſides the principal ſound and its octave, two other very acute ſounds, one of which is the 12th above the principal, or octave of the 5th, and the other the major 17th, or double octave of the ſharp 3d. The principal ſound is called the generator, and the two other ſounds which it engenders, its harmonics, including the octave. See GENERATOR.

Harmonics.



Another, and perhaps a clearer way of ſhewing how a ſtring divides itſelf into its *harmonics*, is by repreſenting the whole ſtring, and indicating the proportions which produce them.

Divide a ſtring into half, and it will produce two octaves of the whole.

Divide it into three parts, and it will produce three 12ths of the whole, or three 5ths of the octave.

Divide it into four parts, and each will be a double octave, or 15th of the whole.

Divide it into five parts, and each will be a *tierce* to the 15th, or a major 17th to the whole.

Rameau, who has built his ſyſtem of *la Baſſe Fondamentale* upon theſe harmonics, has no other natural foundation for the *minor mode* than reverſing the ſounds produced above a given generator, and ſeeking below it what indications he could find in nature for a chord with a flat 3d; and he diſcovered that the 12th and 17th major below a given ſound, below C for inſtance, though they did not ſound, like the harmonics above a grave tone, vibrated very viſibly, and divided themſelves by a kind of undulation, one into three, and the other into five equal parts; whence he drew this concluſion, that theſe vibrating *ſilent* ſtrings pointed out the chord minor of F, thus:  which ſounds approximated, would form the following chord: 
Though d'Alembert ſeemed ſatisfied with this origin of the minor mode, when he publiſhed the firſt edition of his "Elements," mathematicians were offended at the author, Rameau, qualifying a tract in explanation of his ſyſtem, "Demonſtration du Principe de l'Harmonie," and the great

 geometrician,

geometrician, Daniel Bernouilli, attacked d'Alembert himſelf, in the Memoires de l'Academie de Berlin, in 1753, on the ſubject. See BASSE FONDAMENTALE. See alſo the next articles.

HARMONICS, *Acute*, are the ſhrill, high, or very acute ſounds which, like the grave harmonics of two ſounds deſcribed below, are obſerved to accompany a ſingle deep or grave note, in moſt inſtances; particularly in bells, ſome of which give their harmonics, particularly the XIIth, almoſt as ſtrong as the fundamental; and by attending more carefully to the thing, if one of the beſt ſounding ſtrings of the baſe of a piano-forte be ſtruck, we can hear the XIIth very plainly, as the ſound is dying away, and the XVIIth is the laſt ſound that dies away on the ears. Daniel Bernouilli ſeems to have been the firſt perſon who diſcovered the cauſe of the acute harmonics, to which he was led, from contemplating and extending the application of the harmonic curve diſcovered by Dr. Taylor, *viz.* that a muſical ſtring, or the elaſtic column of air in a pipe, at the ſame time that its whole length is vibrating to the fundamental, is capable and diſpoſed to have its two halves, each forming ſubordinate vibrations to the octave, its three aliquot parts, each to vibrate to the main twelfth, its quarters to the double octave, its five aliquot parts each to the major ſeventeenth, &c.: but for want of a proper apparatus, Bernouilli was unable to produce theſe acute harmonics experimentally. The late Dr. Robinſon, being poſſeſſed of a curious wheel monochord, made by the ingenious Mr. Watt about the year 1765, which inſtrument we have already mentioned in our article CONCORD, in experimenting upon it, ſome years afterwards, found that when the ſtring was kept in a ſtate of ſimple vibration, by a very uniform and gentle motion of the wheel, if its middle point was then gently touched with a quill, this point immediately ſtopped, but the ſtring continued to vibrate in two parts, ſounding the octave. And this it continued to do, however ſtrong the vibrations were rendered afterwards, by increaſing the preſſure and velocity of the wheel. The ſame thing happened if the ſtring was gently touched at one third. It inſtantly divided itſelf into three parts, with two nodes, and ſounded the twelfth. In the ſame manner, the double octave and ſeventeenth, and all other harmonics were produced and maintained. But the prettieſt experiment was, to put ſomething ſoft, ſuch as a lock of cotton, in the way of the wide vibrations of the chord, at one-third and two-thirds of its length, ſo as to diſturb them when they became wide. When this was done, the ſtring inſtantly put on the appearance of a figure of 8, performing at once the full vibrations competent to its whole length, and the three ſubordinate vibrations correſponding to one-third of its length, and ſounding the fundamental and the XIIth, with equal ſtrength. In this manner, all the different accompaniments were produced at pleaſure, and could be continued, even with ſtrong ſounds. And it was amuſing to obſerve, when the wheel was ſtrongly preſſed to the ſtring, and the motion violent, the nodes would form themſelves on various parts of the ſtring, running from one part to another. This was always accompanied with all the jarring ſounds which correſponded to them. When the ſtring was making very gentle, ſimple vibrations, and the wheel hardly touching it, if a violoncello was made to ſound the XIIth very ſtrongly in its neighbourhood, the ſtring inſtantly divided itſelf, and vibrated in uniſon, frequently retaining its ſimple vibration and fundamental tone. We recommend this experiment to every perſon who wiſhes to make himſelf well acquainted with the mechaniſm of muſical ſounds. He will ſee, in a moſt ſenſible and convincing manner, how a ſingle ſtring of the Æolian harp gives us all the changes of harmony, ſliding from one ſound to another, according as it is affected in its different parts by an irregular breeze of wind."

Mr. John Hawkins, the inventor of the FINGER-KEYED *Viol*, ſee that article, and whoſe experiment on the concert-pitch is related in that article, during the continuance of his mechanical exhibition ſhewed to his viſitors, a delightful and ocular exhibition of the acute harmonics of a ſtring, as Dr. Robinſon had produced them to the ear, as above quoted. Mr. H.'s apparatus conſiſted merely of a braſs wire 15 or 16 feet long, ſpirally curled through its whole length, (as is done by the baſe ſtrings in his patent piano-fortes, for rendering the inſtrument portable), and ſtretched over two bridges near its two ends, againſt the wainſcot of the room, on which was a ſcale, dividing the ſpace between the bridges into aliquot parts, as $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, &c. through its whole length. The ſtring, thus prepared, was laid hold of by the thumb and finger in the middle, and drawn about two inches out of its quieſcent poſition, and let go, then the tip of the finger, or the feather of a quill being dexterouſly applied, to check the extreme vibrations oppoſite to any one of the aliquot diviſions, the ſtring immediately began to vibrate in ſo many ſeparate parts, without deſtroying the total vibration, which ſtill continued, and ſupported its ſubordinate vibrations for a minute or more, in a manner highly gratifying to the eye, as the vibrations were ſlow enough to be readily counted and compared with each other.

HARMONICS, *Grave*, are deep, low, or very grave ſounds, which, like the acute of a ſingle ſtring above deſcribed, are obſerved to accompany the accordance of two ſounding ſtrings, or pipes, &c. Theſe have two different origins, *viz.* in perfect conſonances, or ſuch wherein the exact ratio of the length of the ſounding ſtring, or numbers of vibrations in a given time can be expreſſed in ſmall numbers; the coincidence of theſe vibrations or pulſes of the ſound occaſion periodical reinforcements of the ſound, which, when they occur oftener than twelve times in a ſecond, affect the ear as independent grave ſounds. In the other caſe of imperfect conſonances, or tempered concords, where the ratios are ſurd, or the numbers expreſſing them very large, the ſmall cycles of pulſes, occaſion, by the periods of their greateſt imperfections, the phenomena called BEATS (ſee that article): if ſuch beats are quicker than twelve in a ſecond, they occaſion a like ſenſation of GRAVE *Harmonic*, which have been fully treated of under that article.

Mr. Holden, in his "Eſſay," p. 300, denominates the grave harmonics, dependents of the conſonance whence they reſult.

HARMONICUS, CANON. See MONOCHORD.

HARMONIDES, in *Biography*, a young flute-player, and ſcholar of Timotheus, who, at the Olympic games, if Lucian may be credited, who relates with the appearance of great gravity, at his firſt public performance, in order to aſtoniſh his hearers, began his ſolo with ſo violent a blaſt, that he breathed his laſt breath into his flute, and died upon the ſpot.

This account is ſo extraordinary, that it ſeems to require the teſtimony of the author's own words: εναπεπνευσεν τω αυλω, *breathed his laſt breath into the flute*; and εν τη σκηνη απεθανε, he died *upon the ſtage*.

HARMONIE DIRECTE, *Fr.* in *Muſic*, is that harmony in which the baſe is fundamental, and in which the upper parts preſerve a regular order with the baſe. *Harmonie renverſée*, or inverted harmony, is that in which one of the treble parts is made

made the baſe, which happens in the chord of the 6th and $\frac{6}{4}$. See DIRECT and INVERTED.

HARMONIST, a muſician learned in harmony. He is a good *harmoniſt*. "Durante," ſays Rouſſeau, "was the greateſt *maſter of harmony* in Italy, that is, in the whole world;" but there are ſome who do not ſubſcribe implicitly to this aſſertion: and regard Leo and Jomelli to be equally profound, and much more *pleaſing harmoniſts*, than Durante: whoſe almoſt only works that are highly prized in Italy, and which have been heard of elſewhere, are his *duets*, formed from the cantatas of his maſter Aleſſandro Scarlatti, which are claſſical and ſtandard ſtudies for the greateſt ſingers.

HARMONOMETRE, an inſtrument calculated to meaſure the relative harmonies. If we could obſerve and follow with the eye and the ear the undulations, the *magic* knots, as d'Alembert calls them, and all the diviſions of a ſtring during its vibration, we ſhould have a natural and very accurate harmonometre; but our ſenſes being too groſs for ſuch nice obſervations, their deficiencies are ſupplied by a monochord, which we divide at our pleaſure, by moveable bridges, that conſtitute the beſt harmonometre hitherto found. See MONOCHORD.

HARMONY. The late citizen of Geneva, Rouſſeau, having treated the ſubject of this article, in his Muſical Dictionary, more amply and intelligently than any other author in the French language, we ſhall try to tranſfuſe into our tongue the chief of his ingenious remarks.

"The ſenſe which the Greeks gave to the word harmony in their muſic, is the more difficult to determine, from its being originally a proper name (Harmonia, wife of Cadmus), and having no roots whence it may be decompounded, in order to extract an etymology. (See the ancient treatiſes which remain.) Harmony ſeems to imply the agreeable ſucceſſion of ſounds, with reſpect to acute and grave, in oppoſition to *rhythm* and *metre*, which concern time and meaſure. This leaves the word harmony ſo vague and indeterminate, that it is impoſſible to fix its preciſe meaning, but by a particular ſtudy of all the ſeveral parts of the art into which ancient muſic was divided," theſe were *ſounds*, *intervals*, *ſyſtems*, *genera*, *modes*, *mutations*, and *melopoëia*, or the compoſition of *melody*, which only comprehend what was denominated harmonies, or the ſcience of muſic, ſtrictly ſo called; but to theſe were added five other requiſites, no leſs eſſential for a muſician to know, than the preceding ſeven: and theſe were *rhythm*, or the regulation of cadences in all kinds of movement; *metre*, or the meaſure of verſes; *organic*, or the inſtrumental art; *hypocritic*, or *geſture*; and even to theſe diviſions, Ariſtides Quintilianus, and ſome others, add *delicum*, or the art of ſinging," and ſtill (adds Rouſſeau) harmony will be very difficult to diſtinguiſh from melody.

"We ſee by a paſſage from Nichomachus, and by others, that ſometimes the name of harmony was given to conſonance in the octave, and to concerts of voices and inſtruments formed of uniſons and octaves, which were generally termed *antiphons*.

"Harmony, according to the moderns, is a ſucceſſion of chords agreeable to the rules of modulation. This harmony for a long time had no other principles than laws almoſt arbitrary, founded on the judgment of practiſed ears, which determined what were good or bad ſucceſſions of concords, but which, at length, were reduced to calculation. However, Père Merſenne, and M. Sauveur, having diſcovered that every ſound, though ſeemingly ſingle, was accompanied by two other more feeble ſounds, which formed, with the principal, the perfect chord major, M. Rameau, upon the baſis of this experiment, has built an harmonical ſyſtem, with which he has filled many obſcure books, and theſe M. d'Alembert at length took the trouble to explain to the public."

Here we muſt ſtop to correct a miſtake of this lively writer: it was neither Père Merſenne, nor M. Sauveur, who diſcovered the *ſons harmoniques*, or harmonics of the 12th and major 17th, which accompany every muſical ſound, but Galileo Galilei. See his article, and *Baſſe* FONDAMENTALE.

And M. d'Alembert in the 2d edit. of his "Elements of Muſic, on the Principles of Rameau," diſputes his origin of the minor mode, and denies that any part of his ſyſtem will admit of demonſtration.

"Tartini, ſetting off from another experiment, more novel, more delicate, and not leſs certain, arrived at ſimilar concluſions, by a very different road. Rameau made the baſe produce the treble; Tartini made the treble generate the baſe. The latter derives *harmony* from melody, the former the contrary. To determine from which of theſe two ſchools the beſt works are likely to proceed, we have only to conſider which ought to be ſubordinate to the other, the melody or the accompaniment." See SYSTEM, HARMONICS, FUNDAMENTAL BASE, TERZA SUONA, COUNTERPOINT, and COMPOSITION.

Of all the paradoxes of this eloquent and powerful writer, none will ſurpriſe muſicians more than the following, with which he cloſes the preſent article in his Muſical Dictionary.

"When we reflect, that of all the inhabitants of the earth, who have muſic, the Europeans alone are fond of harmony, and delighted with different parts, moving at the ſame time; when we remember how many ages the world has endured, without any one nation that has cultivated the fine arts, in any of the other three quarters of the globe, diſcovering this harmony; that no animal, no bird, no being in nature, produces any other conſonance than uniſon, nor other muſic than melody; that the oriental languages, ſo ſonorous, ſo muſical; that the ears of the Greeks, ſo acute, delicate, and exerciſed with ſo much art, have never guided this voluptuous and impaſſioned people towards our harmony; that without it their muſic has produced ſuch prodigious effects; that with it, thoſe of our muſic are ſo feeble; and, laſtly, that it ſhould be reſerved for people of the north, whoſe organs are groſs and obtuſe, to be more touched with the clangor and noiſe of warring ſounds, than with the ſweet accents, and melody of inflections, to make this great diſcovery, and to eſtabliſh it as a principle in all the rules of the art; when, I ſay, we reflect on all theſe circumſtances, it is very difficult to avoid ſuſpecting, that all our harmony is but a Gothic and barbarous invention, which would never have occurred to us, if we had been more ſenſible to the true beauties of the art, and to muſic truly natural.

"Rameau, however, pretends, that harmony is the ſource of the greateſt beauties in muſic; but this ſentiment is confuted by facts and reaſon. By facts, from all the great effects of muſic having ceaſed, and that it has loſt its force and energy, ſince the invention of counter-point; to which I muſt add, that the beauties of what is called fine harmony, are thoſe of learning, and often of pedantry, which only tranſport perſons deep in the myſteries of the ſcience; whereas the true beauties of muſic being thoſe of nature, are, and ought to be, equally felt by all men, learned and ignorant. By reaſon, ſince harmony furniſhes no principle of imitation, by which muſic awakening images, or expreſſing ſentiments, can mount up to the drama, which is the moſt noble, and the only energetic part of the art; all that depended on ſimple, natural ſounds, being much circumſcribed in the

pleaſure they afford, and having very little power over the human heart."

We ſhall leave the excluſive admirers of melody and harmony to fight it out, and declare that we never wiſh to hear melody without harmony, or harmony without melody. Whenever theſe two ſiſters quarrel, and ſet up different intereſts, they mutually injure each other, and diſpleaſe their beſt friends.

Iſidore's definition of harmony is a proof that, with the ancients, it only implied *melody*. "Prima diviſio muſicæ quæ harmonica dicitur, id eſt, modulatio vocis—non vocum."

HARMONY, *figurative*, in oppoſition to the harmony of common chords, or note againſt note, otherwiſe called *plain counterpoint*. It had its title of *figurative* after the invention of the time-table, when different figures or notes were uſed from thoſe of canto-fermo, commonly called Gregorian. See GREGORIAN and FIGURATIVE.

HARMONY, *Perfect*, of *Maxwell*, is a ſyſtem of muſical ſounds, 44 within the octave, invented by Mr. Maxwell of Broomholme in Scotland, the application of which, to the violin and other bowed inſtruments, is fully explained in his "Eſſay on Tune," printed at Edinburgh in 1781, and wherein ſome hints are given towards its application to the organ, of which, unfortunately, no muſical mechanic has yet availed himſelf, and effected, on this noble inſtrument, the grand *deſideratum* of inſtrumental muſic, whereby a correct concert of voices, or perfect inſtruments, wherein every concord throughout the piece ſhall be perfect, and without temperament, or beats, may be certainly and correctly imitated. See MAXWELL's *Scale of Intervals*.

HARMONY, *Equal*, of Dr. *Smith*, comprehends ſyſtems of muſical intervals, inveſtigated by this author in his "Harmonics;" the principles of which are, that every concord therein ſhall be equally, and the moſt harmonious, that the unalterable nature of the ſcale will admit, according to the compaſs or extent of it; thus, for the compaſs of one octave, Dr. Smith calculates (p. 153. 2d edit.) that the major thirds muſt all be flattened $\frac{1}{3}$'th of a major comma, or 1.3455 Σ: for the compaſs of two octaves, the IIIds muſt be flattened $\frac{1}{8}c$, = 1.3670 Σ: for the compaſs of three octaves, the temperament muſt be III$-\frac{1}{4}c$, or 1 2231 Σ: and for the compaſs of four octaves (p. 140, note.) III $-\frac{1}{10}c$, or more nearly, the temperament is 1.0865 Σ. For ſeveral reaſons, Dr. Smith preferred the ſyſtem of equal harmony in three octaves, and ſhews (p. 156.) that the ſame approaches indefinitely near to a commenſurate ſyſtem of 50 equal parts in the octave, without, however, any where mentioning, that this is the ſyſtem of Mr. Heuſſing (Hiſt. de l'Acad. 1711, 16mo. p. 406.), as obſerved by Mr. Farey, in the Philoſophical Magazine, vol. 36. p. 49; by whoſe theorems, p. 41, or corollaries, p. 374, of the ſame volume, all the temperaments in either of the above ſyſtems can readily be calculated, and the ſeveral wolves alſo, which will ariſe in applying the ſame to the common inſtrument with only 12 notes in the octave, or even to Dr. Smith's own improved harpſichord, whenever modulation is made, ſo far as to require double flats, or double ſharps; but which can now be uſed, even on the organ, as well as the piano-forte, without any wolves, as far as two double ſharps and one double flat; on the patent inſtruments of M. Loeſchman of Newman-ſtreet, whoſe organs in particular far exceed any thing hitherto effected in muſical inſtruments. The above ſyſtems, by Dr. Smith, are all for equalizing the harmony of the ſeveral *concords*, with reſpect to each other: a different object is aimed at by ſome theoriſts and tuners, *viz.* making all the twelve ſeveral keys equally harmonious, with reſpect to each other, and conſequently equally tempered, which is the EQUAL *temperament*, or ISOTONIC *ſyſtem*, (which ſee,) but this ought not to be called equal harmony, as Mr. Emerſon, and ſome other writers, have done.

HARMONY, *Temperaments of*, are applied to the temperaments of the intervals, in common keyed inſtruments, or imperfect inſtruments, where the ſame temperaments neceſſarily apply alſo to the *melody*, or leaps from one note to another: but in a paper by Mr. Farey, in the Philoſophical Magazine, vol. 27. p. 206 and 314, it is ſhewn, that good performers on perfect inſtruments, and correct fingers, make no temperaments in the harmony, but throw the ſame entirely into the melody or leaps, ſo as to produce every chord or conſonance of notes heard together *perfect* throughout their performance, at leaſt, they can do ſo, if ſkilful and ſufficiently careful; and it is truly aſſerted, that they never attemper their harmony by deſign, as a tuner of imperfect inſtruments is forced to do, and hence the vaſt importance of the inſtruments for yielding perfect harmony, on the theory and conſtruction of which Mr. Maxwell has ſo ably exerted himſelf; ſee his "Eſſay on Tune."

HARMONY is ſometimes alſo uſed, in a laxer ſenſe, to denote an agreement, ſuitableneſs, union, conformity, &c. In muſic we ſometimes apply it to a ſingle voice, when ſonorous, clear, and ſoft; or to a ſingle inſtrument, when it yields a very agreeable ſound. Thus we ſay, the harmony of her voice, of his lute, &c.

In *Matters of Learning*, we uſe harmony for a certain agreement between the ſeveral parts of the diſcourſe, which renders the reading thereof agreeable. In this ſenſe we ſay, harmonious periods, &c.

In *Architecture*, harmony denotes an agreeable relation between the parts of a building. See SYMMETRY.

In *Painting*, they ſpeak of a harmony, both in the ordonnance and compoſition, and in the colours of a picture. In the ordonnance it ſignifies the union or connection between the figures, with reſpect to the ſubject of the piece. In the colouring it denotes the union or agreeable mixture of different colours. (See COLOURING.) M. De la Chambre derives the harmony of colours from the ſame proportions as the harmony of ſounds. This he inſiſts on at large, in his treatiſe of the Colours of the Rainbow. On this principle, he lays down green as the moſt agreeable of colours, correſponding to the octave in muſic; red, to a fifth; yellow, to a fourth, &c. See HARMONY, in *Painting*.

The term *harmony* is frequently uſed metaphorically for various things which have no connection with ſound or practical muſic; as the harmony of colours in painting; the harmony of numbers in poetry; harmony in the ſeveral offices, departments, and orders of a ſtate; harmony in a family.

HARMONY, or *Evangelical Harmony*, is alſo a title of divers books, compoſed to ſhew the uniformity and agreement of the accounts given by the four evangeliſts, by reducing them to the order of time in which the events recorded really happened.

The firſt attempt of this kind is attributed to Tatian or Theophilus of Antioch, under the title of Diateſſaron, or *of the four*, in the ſecond century. After his example, divers other harmonies have been compoſed by Ammonius of Alexandria, about the year 220, Euſebius of Cæſarea, about 315, Oſiander, Janſenius biſhop of Ghent, Mr. Toinard, Mr. Whiſton, Lamy, Le Clerc, Doddridge, Macknight, Pilkington, Prieſtley, Newcome, &c. Theſe ſeveral harmonizers have entertained very different opinions with regard to the period of our Lord's public miniſtry, which have neceſſarily occaſioned a correſponding diverſity in the diſpoſi-

tion

tion of their reſpective harmonies. Dr. Prieſtley, in a work of this kind, publiſhed in 1777, has adopted the opinion propoſed by Mr. Mann, in his Diſſertations on the Times of the Birth and Death of Chriſt, and ſtrenuouſly maintained, that he preached no longer than one year, or one year and a few months. This opinion is, undoubtedly, very ancient: it was the opinion of Origen, and alſo of Clemens Alexandrinus: Irenæus and Tertullian aſcribe the ſame opinion to the Valentinians. See Origen. De Princip. lib. iv. § 5. apud Oper. tom. i. p. 160. ed. Benedict. Clem. Alex. Strom. lib. i. p. 340. ed. Sylb. vel. apud Oper. tom. i. p. 407. ed. Oxon. Iren. lib. i. cap. 3. num. 3. Tertull. lib. Adverſus Judæos, cap. 18.

However it has been objected by others, and particularly by biſhop Newcome, in his Harmony of the Goſpels, publiſhed in 1778, that this period of one year is much too ſhort for the ſeveral journies of our Saviour in Galilee, and the tranſactions connected with them; and he has offered ſeveral arguments to prove the more common opinion, firſt advanced by Euſebius, *viz.* that our Lord's miniſtry continued three years and a half, and included in that ſpace of time four paſſovers. Sir Iſaac Newton is of opinion, that our Lord's miniſtry included five paſſovers; the firſt of which happened A. D. 30; the ſecond A. D. 31; the third A. D. 32; the fourth A. D. 33; the fifth on Friday, April 23, A. D. 34; anſwering to the 4747th year of the Julian period. See his Obſervations on Prophecy, book i. chap. xi. p. 144.—168.

Harmony *of the ſpheres*, or *celeſtial harmony*, is a ſort of muſic much ſpoken of by many of the philoſophers and fathers; ſuppoſed to be produced by the regular ſweetly-tuned motions of the ſtars and planets.

Plato, Philo Judæus, St. Auguſtine, St. Ambroſe, St. Iſidore, Boethius, and many others, are ſtrongly poſſeſſed with the opinion of this harmony, which they attribute to the various proportionate impreſſions of the heavenly globes upon one another, which, acting under proper intervals, form a harmony. It is impoſſible, according to them, that ſuch ſpacious bodies, moving with ſo much rapidity, ſhould be ſilent; on the contrary, the atmoſphere, continually impelled by them, muſt yield a ſet of ſounds proportionate to the impulſions it receives: conſequently, as they do not all run the ſame circuit, nor with one and the ſame velocity, the different tones ariſing from the diverſity of motions, directed by the hand of the Almighty, muſt form an admirable ſymphony or concert. St. Irenæus, St. Baſil, and St. Epiphanius, &c., have appeared againſt the notion.

Pythagoras is ſuppoſed to have had a view to the gravitation of celeſtial bodies, in what he taught concerning the harmony of the ſpheres.

A muſical chord gives the ſame notes as one double in length, when the tenſion or force with which the latter is ſtretched is quadruple; and the gravity of a planet is quadruple of the gravity of a planet at a double diſtance. In general, that any muſical chord may become uniſon to a leſſer chord of the ſame kind, its tenſion muſt be increaſed in the ſame proportion as the ſquare of its length is greater; and that the gravity of a planet may become equal to the gravity of another planet nearer the ſun, it muſt be increaſed in proportion as the ſquare of its diſtance from the ſun is greater. If, therefore, we ſhould ſuppoſe muſical chords to extend from the ſun to each planet, that all theſe chords might become uniſon, it would be requiſite to increaſe or diminiſh their tenſions in the ſame proportions as would be ſufficient to render the gravities of the planets equal; and from the ſimilitude of thoſe proportions, the celebrated doctrine of the harmony of the ſpheres is ſuppoſed to have been derived. Plin. lib. ii. cap. 22. Macrob. in Somn. Scrip. lib. ii. cap. 1. Plutarch de Animal. Procreatione, è Timæo. See Maclaurin's View of Newton's Diſcov. book i. chap. ii. p. 32. ed. 4to. See Gravity.

Harmony, *pre-eſtabliſhed*, a celebrated ſyſtem of M. Leibnitz, by means whereof he accounts for the union or communication between the ſoul and body.

The philoſophers had univerſally held, that the ſoul and body act really and phyſically on each other. Des Cartes firſt appeared, and ſhewed that the heterogeneity of their nature did not allow of ſuch real union; and that they could only have an apparent one, whereof God is the mediator.

M. Leibnitz, unſatisfied with either of theſe hypotheſes, eſtabliſhes a third. A ſoul or ſpirit, he obſerves, is to have a certain ſeries of thoughts, deſires, and wills: a body, which is only a machine, is to have a certain ſeries of motions, to be determined by the combination of its mechanical diſpoſition with the impreſſions of external objects.

If, now, there be found a ſoul and body ſo framed, that the whole ſeries of wills of the ſoul, and the whole ſeries of motions of the body, exactly correſpond; and at the ſame time, for inſtance, when the ſoul deſires to go to any place, the two feet move mechanically that way; this ſoul and body will have a relation to one another, not by any actual union between them, but by the conſtant and perpetual correſpondence of the ſeveral actions of both. Now, God puts together this ſoul and body, which had ſuch a correſpondence antecedent to their union; ſuch a pre-eſtabliſhed harmony. And the ſame is to be underſtood of all the other ſouls and bodies that have been, or ever will be joined.

In effect, the laws of motion in the body, ſucceeding in the order of efficient cauſes, do alſo agree and correſpond with the ideas of the ſoul; ſo that the body is determined to act at the time when the ſoul wills. So that upon this hypotheſis, the volitions of the mind are followed inſtantly by the deſired motions of the body, not in conſequence of thoſe volitions in the leaſt, but of the nice and well-adjuſted machinery of the body; and the impreſſions produced in the ſenſory have no effect on the mind, but the correſponding idea ariſes, at that preciſe time, in conſequence of a chain of cauſes of a different kind; and, therefore, all that men do or ſay, is no more than the effect of exquiſite machinery.

The ſame principle he extends farther, and makes a pre-eſtabliſhed harmony between the kingdoms of nature and grace; to account for the apparent communication between them, and make phyſical and moral evil correſpond.

Such is the ſyſtem of pre-eſtabliſhed harmony. The author's way of ſtating and enforcing it, may be ſeen in his Eſſais de Theodicée.

This hypotheſis was firſt publiſhed in the Journal des Sçavans of Paris, in 1695, and ſtrenuouſly defended by Wolfius, who, on this account, was baniſhed by Frederick, king of Pruſſia; it is oppoſed by Bayle, in the article Borarius of his Dictionary, and ſince his time by Newton, Clark, Stahl, &c. See Leibnitzian *philoſophy*.

Harmony, in *Geography*, a townſhip of America, in Kennebeck county, near Cornville; incorporated in 1803.—Alſo, a village in Luzerne county, Pennſylvania, between which and Stockport on Delaware river, diſtant 18 miles E.S.E. there is a portage; about 140 miles N. by W. of Philadelphia. N. lat. 41° 53'.

Harmony, in *Painting*. The analogy which exiſts between the impreſſions received by the mind through the different agency of hearing and of ſight, either producing agreeable or affecting ſenſations, or being of moral utility, neceſſarily cauſes a correſpondence in the words which deſcribe thoſe impreſſions. Hence the word *harmony*, which, in muſic,

ſignifies a perfect accordance between the various parts of a compoſition, and alſo of ſound in the inſtruments by which it is performed, is adopted in the art of painting, wherein it has a ſignification of a correſpondent nature, being applied to the united effects of the parts viewed as a whole, and to the lines, colours, and expreſſions with which it is wrought.

As in one art the various tones of different inſtruments, though ſo extremely unlike ſpecifically, are brought by tuning to one key, and thereby made to produce one whole harmonious ſound, or rather mixture of ſounds, to the ear; ſo in the other, different and violently oppoſing lines and colours, which are its inſtruments of expreſſion, may, by contraſt, arrangement, and the admixture of intermediate degrees of each, be made to unite in one agreeable effect to the eye; or, in the painter's language, become *harmonious* in their union, a word ſignifying, in both arts, an agreeable impreſſion on the mind, ariſing from an ingeniouſly regulated combination of parts, naturally diverſified, and ſome even oppoſite to each other in their peculiar qualities.

Mengs, in his practical leſſons on painting, ſays, that an "union of various colours is improperly called harmony, becauſe that appertains to thoſe things alone that have time, quantity, extenſion, or any other dimenſion that can produce a correſpondence of one thing with another;" and argues abſtruſely on "the neceſſity of numbering the degrees of the angles of refraction which the rays of light form in a priſm, which would be an immenſe ſtudy alienate from painting, and be entirely uſeleſs to painters."

His commentator, the chevalier Azara, has judiciouſly oppoſed this opinion, and clearly is right when he ſtates that he "believes there is a true harmony in colouring. A ray of light (he ſays) can cauſe upon our optic nerve a ſtrong or a weak ſenſation, and another ray can at the ſame time produce a different ſenſation which temperates and moderates the firſt; ſo that either of theſe two ſenſations will be ſometimes in itſelf alone diſagreeable, by vibrating our organs more or leſs than is neceſſary; yet they will have a good effect together, the one correcting the exceſs and defects of the other." Similar to this is the baſis of harmony in ſounds; and if, as the chevalier obſerves, rays of light may produce different, and conſequently inharmonious effects upon our viſual organs, how infinitely greater will be thoſe diverſities when colours are ſuperadded in their own natural intenſity, and under the influence of different degrees of light? Who can for a moment conceive that the operation of a violent red, in a ſtrong light, will not affect the eye in a manner totally different from a faint blue, in a leſs degree of illumination? or that theſe two oppoſite colours may not, the quality of one being weakened, and that of the other ſtrengthened, and both placed in an equal degree of light, be ſo regulated as to correſpond in their degree of intenſity of action on the eye? This very power, therefore, of regulating the effect of each colour by degrees, either by the admiſſion of light or dark, by giving each its full force, or weakening it by the admixture of different colours, proves the adoption of the word to be judicious and proper, even upon Mengs' own propoſition, becauſe there muſt be, in this caſe, a ſcale of regulation to act upon; but he is right in ſaying, it would require too tedious a ſtudy to reduce it to rule, and ſtill more to apply it to practice.

From the ſame art, and through the ſame agency whence this word *harmony* is borrowed, painting has alſo adopted another, without which it is impoſſible to explain the principles of the former in this art, *viz. tone*.

In muſic, this word denotes the peculiarity of the ſound in an inſtrument or voice. In painting, it ſignifies the peculiar governing hue which a picture or colour poſſeſſes. In the former, we ſpeak of a high or a low, a ſweet or a ſhrill-toned inſtrument, &c. In the latter the ſame appellations, or nearly ſo, are employed, with the exception of thoſe terms which preciſely belong to hearing, and the application of thoſe which appertain to viſion only; ſuch as the names of colours, as grey, brown, &c. If a picture have a great portion of light colours, and thoſe are wrought with a ſprightly free touch, it will come under the denomination of a light, or bright-toned one. If, on the other hand, the larger maſs of colours is deep and dark, and the lights not very brilliant and ſparkling, it is ſaid to be of a deep or low tone. The meaning of the other terms, indicating colours, is obvious.

The adoption of this latter word, *tone*, in painting, is completely arbitrary, its ſenſe, which is ſimply ſound, having no analogy to any part of painting, which addreſſes itſelf to the underſtanding ſolely through the medium of the eye. It has probably grown into uſe with harmony (which, as we have ſhewn, is correctly applied in both arts), and without any other ground of ſupport than an intuitive comprehenſion of its meaning when ſo uſed, which moſt men feel, without conſidering wherefore.

The principle upon which *harmony in painting* depends, ſeems to be, that all the hues of a picture ſhould have a correſpondent degree of intenſity, or, in the technical phraſe, be of the ſame tone, however they may vary in their degrees of light and dark; juſt as in a piece of muſic, which is intended to be played in one key, though the notes are high and low, yet none ſhould be introduced that do not belong to that key.

If it be intended that a picture ſhould have a ſolemn effect (ſee EFFECT), the tone ſhould be deep, that is, dark hues ſhould prevail, and no extremely vivid colour, as pure red or blue, ſhould be admitted; but that kind of effect ſhould be ſpread over the whole which occurs in nature at twilight, when every object loſes ſomewhat of its daylight-brilliancy of colour, and receives a deadened, darkened aſpect, the privation of light diminiſhing its luſtre, and reducing its appearance to a grever tone. If, in this caſe, a bright red or white, &c. ſhould be introduced as bright as if ſeen by daylight, the harmony would be deſtroyed; and the reaſon is apparent, *viz.* two cauſes, ſo diſtinct as light and darkneſs, cannot operate to produce the ſame effect. When, in reverſe of this, gaiety and bright daylight are the ruling principle in the effect intended, clear bright colours muſt be introduced, care being taken that they are of one degree of brilliancy in the illumination, according to the arrangement of chiaroſcuro.

Something ſimilar to the introduction of the half-tone in muſic to produce harmony, is the value of half-tone or half-teint in painting (ſee HALF-TEINT); but with this diverſity, that in the latter art it conſtitutes the far greater part of a compoſition, as relative to colour; whereas in the former, it is more rarely introduced. In painting, half-tones are conſtantly required to unite the primary colours, or local colours, as they are termed: and every round object in paſſing to darkneſs on its ſhaded ſide, by degrees loſes the purity of its colour, as its quantity of light decreaſes; and throws off its rays of reflection in different direction from its front parts; becoming thereby gradually in the ſituation twilight would produce upon it. Even in the very front of an object, if it have a rough ſurface particularly, ſmall degrees of variation of colour will be obſervable, cauſed by the ſhadows produced by its ſuperficial irregularity. Hence a flat broad maſs of one even colour, will always have an unpleaſant effect in a painting, becauſe an untrue one; ſmall portions of broken tones muſt mix even in the higheſt lights, to render it a delicate,

cate, beautiful, and juſt imitation of the harmony and richneſs which always reigns in nature.

Richneſs, in the harmony of a picture, very much depends on the arrangement of the colours. The rainbow is a proof, and the beſt exemplar of this. Its beauty has been always recognized, and has been juſtly extolled by poets, and inefficiently attempted to be imitated by painters. In it not only each primary colour, the red, the blue, and the yellow, have equal degrees of intenſity and conſequent harmony, but the extreme ſubtlety and ſoftneſs of their mutual approximations, by gradually blending their hues, produce the utmoſt delight which colours are capable of affording.

Not a little of this delight is owing entirely to the arrangement of the colours. Let us ſuppoſe, that inſtead of the warm hues of the red and yellow being in the centre, the blue had been tranſpoſed to that ſituation, and not diſtributed towards the boundary of the bow! would it have been ſo agreeable to the eye? In that caſe the greater part of the maſs of colour would have been of a cold hue; for the blue, ſpreading both ways, and producing green on the one ſide, and purple on the other, while the glowing teints of red and yellow were confined to the edges, and no orange colour at all produced; all the preſent rich vividity of its effect would be loſt, and it would neceſſarily have preſented a far leſs pleaſing object to the view. This remark, however, rather belongs to the ſyſtem of colouring than to that of harmony ſtrictly ſpeaking, for the harmony might be equal in either caſe, though the effect be far leſs agreeable. Something of this is nevertheleſs requiſite to produce harmony in widely extended compoſitions in painting. It ſeems neceſſary, then, that colours ſhould have their repetitions ſpread through the whole ſurface, upon the ſame principle as they are arranged in the rainbow, or they will not unite agreeably, nor form a perfect whole.

As well as in the colouring of a picture, there ſhould alſo be an harmonious concord in the lines; which ſhould unite together in an agreeable manner, without violent contraſts, except where they may be neceſſary for the better expreſſion of the ſubject. And the work ſhould altogether, and in every part, have one character of deſign, as far as is agreeable to the nature of the different objects introduced. If one part of a figure for inſtance be drawn with ſquare forms and angular lines, and in certain proportions; no other parts ſhould have flowing lines, or be of different proportions, each of theſe being the means of repreſenting different ſpecific characters, and two characters can never be found in nature in the ſame figure. Thus one hand ſhould be made viſible through the whole picture, and no unequal or diverſified power appear in it; even in making various and oppoſite expreſſions.

The expreſſions themſelves ſhould tend to one point, to inculcate one moral; there ought in this reſpect to be an harmony, an uniſon, among them; they ſhould all co-operate to produce one total, and never lead the mind of the obſerver aſtray from the ſubject of the picture.

The moſt important point to attend to, in the production of harmony in painting, is the ſhade teint, or that hue of colour of which the ſhadows are compoſed; more particularly in its union with the lights, that is, in the production of half-teint. Shadow, in the eye of the painter, is not blackneſs, but a colour poſſeſſing richneſs and warmth; whoſe appropriate hue varies according to the nature of the ſubject and circumſtances of the compoſition. It has been ſhown, that the far greater part of the ſurface of all rounded bodies preſents half-teint to the eye. If the ſhade colour be well choſen, this half-teint will be effected by its mixture with the local colours of the lighter parts of the picture; and if it be regularly employed through the whole, harmony will neceſſarily be produced. Much attention is however requiſite, not to let this hue enter too far, or in too great a degree, into the body of the colouring; otherwiſe monotony will be the conſequence, which is the very bathos of harmony.

The ſimpleſt ſhade colour that can be employed is umber unburnt; but its want of depth of tone makes it inadequate to produce great force of effect; and the half teint which it makes in mixture with the local colour, requires, as it approaches the light, an intermixture of grey to give it clearneſs; eſpecially in preparations or dead-colouring, in order to prevent the glazings employed for finiſhing, rendering the work too dull and brown. It appears to have been the colour moſt in uſe by Titian and Vandyke for the baſis of their ſhadows, as may be collected by examining their works, which are always ſtrengthened by glazing at the laſt. It is alſo, when judiciouſly employed with ſlight intermixtures of other colours (according to circumſtances) an excellent tone of colour for a general glazing; that is, giving one harmonious teint over the whole; but care muſt be had in the uſe of it, for time and the dirt which will accumulate upon the ſurface of a picture, will in a few years increaſe its depth by ſuperadding another tone of a ſimilar nature.

Titian, Giorgione, and Correggio are the great original exemplars of harmony of colouring, though the mode in which it was produced by the latter, differed exceedingly from that of the two former. A careful examination of their works, to which may be added thoſe of Vandyke and ſir Joſ. Reynolds, is the beſt mode of obtaining a juſt underſtanding of it, and of becoming enabled to put it in practice.

HARMOS, from ἁρμω, *apto*, *I fit*, a word, uſed by the old medicinal writers, for the fleſh growing between the teeth.

HARMOSTES, or HARMOSTA, in *Antiquity*, a ſort of magiſtrate among the Spartans, whereof there were ſeveral, whoſe buſineſs was to look to the building of citadels, and repairing the forts and fortifications of the cities.

The word is ἁρμοστης, formed of ἁρμοω, *apto*, *concinno*, *I adapt*, *concert*, &c.

HARMOSYNIANS, ἁρμοσυνοι, were magiſtrates among the Spartans, who, after the death of Lycurgus, were appointed to enforce the obſervance of that law of the Spartan legiſlator, which required married women to wear a veil when they appeared in the ſtreets, whereby they were diſtinguiſhed from ſingle females, who were allowed to appear abroad with their faces uncovered.

HARMOTOME, in *Mineralogy*, a name given by the celebrated French cryſtallographer to a mineral which was, and is ſtill, more commonly called *croſs-ſtone*, (kreutz-ſtein in German,) on account of the form its cryſtals are frequently ſeen to affect. It is likewiſe known by the names of *andreolite* and *andreasberg-olite*, given to it by Lametherie, from the place where it was firſt diſcovered. We adopt Haüy's name, partly becauſe it does not, like that of "croſs-ſtone," ſubject this ſubſtance to be confounded with what is now called grenatite, ſtaurotide, or ſtaurolite, (indeed, the laſt of theſe names is given by Kirwan to the croſs-ſtone,); partly becauſe the mineral is not excluſively found at Andreasberg; and, above all, becauſe we would adopt any name rather than omit this very intereſting mineral, which has not been mentioned in this work under either of the above appellations. Bergmann, and after him Romé de Liſle, applied to the croſs-ſtone the name of *cruciform white hyacinth*, conſidering it as a variety of what is now called zircon,

zircon, from which, however, it is perfectly distinct, not only by the cleavage of the crystals, its specific gravity, &c. but particularly, as later analyses have shewn, by its chemical composition.

The colour of the harmotome is greyish-white, approaching to smoke-grey, sometimes yellowish and milk-white: the greater its transparency, the more it approaches to colourless. It occurs always crystallized.

The *primitive form* of the crystals is, according to Haüy, a rectangular octahedron, composed of isosceles triangles, and divisible in the direction of planes that may be supposed to pass through the edges which meet at the summit, and through the centre of the octahedron. Mr. Von Buch, in a memoir on this subject, read before the Linnæan Society of Leipzig, as early as the year 1793, considered the nucleus of the cross-stone to be a rhomboid, two of whose angles he computed to be between 92° and 110°, the two others between 70° and 88°. This opinion, founded on the direction of the striæ observable on the acuminating planes of the crystals, has since been objected to, partly on account of its insufficiency to explain the different modifications of the secondary crystals, and partly because these crystals are not divisible in the direction of the striæ of the surfaces. But the latter of these objections would be applicable also to the crystals of other substances, such as the striated octahedrons of oxyd of tin, &c. which are equally indivisible in the direction of the laminæ indicated by the striæ. It happens but too frequently, in cases where the cleavage is not perceptible, that the crystallographer, in determining the primitive form, must have recourse to gratuitous assumption: indeed, in the mineral under consideration, we might, perhaps, derive the secondary forms, with equal facility, from the rectangular prism, as from the octahedron; in which case, the mode of viewing the secondary crystals would, of course, be diametrically opposite to the other. In adopting the rectangular octahedron for the nucleus, we shall follow Haüy and Hausmann in the description of the secondary crystals hitherto noticed.

I. *Simple Crystallization.*

1. The dodecahedron, with rhomboidal planes. The angles of the eight planes, supposed to be parallel to those of the nucleus, are, according to Hausmann, of 72° 5′ 54″, and 107° 54′ 6″: the four secondary rhomboidal planes have angles of 73° 44′ 8″, and 106° 15′ 52″. Sometimes two of the latter planes become very small, and even disappear when the crystal adopts the form of a rhomboidal solid bevilled at the edges.

This modification is formed by the super-position of laminæ on all the planes of the octahedron, and by the decrement of a single row of molecules on its four lateral solid angles. If many rows of molecules are super-imposed on one another, and the crystal is lengthened according to the same laws of decrement, this form passes into that of

2. The rectangular four-sided prism, acuminated at both ends by four planes set on the lateral edges. (*Harmotome dodécaèdre*, Haüy, pl. 59. fig. 195.) The four lateral planes are hexagons with two angles of 106° 15′ 52″, and four others of 126° 52′ 4″. The edges formed by the eight planes of acumination, being the primitive planes, form, like those in the preceding modification, angles of 121° 57′ 56″. Often two adjacent acuminating planes enlarge at the expence of the two others, which sometimes even disappear.

3. The rectangular four-sided prism, terminated at each end by six planes, four of which are placed on the lateral edges (being the former modification), and two on two opposite lateral planes. (*Harmotome partiel*, Haüy, pl. 59. fig. 196.) The two latter planes (if the octahedron is the primitive crystal,) are to be considered as truncations of two opposite terminal edges of the preceding modifications: and they originate by a simple decrement of the molecules at both sides; the four lateral planes, hexagonal before, become octagons with four angles of 126° 52′ 4″, and four others of 143° 7′ 32″. The proportion of the sides of these and the rhomboidal planes depends on the magnitude of the truncating planes. These meet with the lateral planes under an angle of 123° 41′ 24″; and with the rhomboidal terminal planes under one of 150° 58′ 58″.

If these truncating planes encrease to such a degree as to make the rhomboidal terminal planes disappear, the crystal represent

4. The rectangular four-sided prism bevilled at two extremities. (Buch Kreutzst. fig. 11.) Two of the lateral planes are rectangular; the two others hexagons, with the two angles of 112° 37′ 12″, and four others of 126° 52′ 4″. The height of the prism is often considerably diminished in proportion to the other dimensions; sometimes to such a degree, that the two rectangular lateral planes disappear entirely, in which case this variety passes into the

5. Oblique four-sided prism, whose sides are analogous to the bevilling planes of var. N° 4, and the ends to the two six-sided lateral planes of the preceding modification. Hence, it has two of its lateral edges of 112° 37′ 12″, and two others of 67° 22′ 48″.

II. *Twin-Crystals.*

These being much more common than the simple crystals, (those of the Hartz are seldom found simple,) the harmotome has obtained the name cross-stone by those who first observed this mineral. These composed crystals are by no means individuals, but they actually consist of two different crystals, one of which is traversed by the other. This is a macle of a peculiar kind.

These twin crystals are not always of the same form; the more common are those composed of two of the dodecahedral crystals No. 2, that are wider in one direction than in the other, and crossing each other longitudinally, under a right angle, so that they have a common axis. (*Harmotome cruciforme*, Haüy, plate 49, fig. 197.) Also Var. Nos. 1, 3, and 4 occur combined in this manner.

Besides these symmetrical twin crystals, there occur others, composed in a similar manner, but of two different varieties, such as of N° 1, combined with Nos. 2, 3, 4, and 5, (in which the var. N° 1 is always of posterior origin to the others); or of var. N° 2, with var. Nos. 3, 4, and 5, and of var. N° 3, with var. Nos. 4 and 5; as likewise of var. N° 4, with var. N° 5, in which combination the prism N° 4, is of prior origin, and halves of N° 5 are placed on its broader sides.

In the prismatic twin crystals, one of the halves of the secondary prisms is sometimes wanting, oftener they are perfect on both sides, and commonly placed exactly in the middle of the broader planes of the primary prism; and rarely the two halves on one or both broader planes are interrupted towards their middle.

The size of the crystals varies from nearly an inch, to scarcely the fourteenth part of an inch: the largest and thickest are those of Strontian; very minute crystals are found on the Hartz. They are always grouped together.

Surface smooth; but in those of the Hartz, the magnifying glass generally discovers, on the narrower planes of the rectangular four-sided prisms, pinnated striæ: namely, on each a longitudinal stria, with lateral striæ directed downwards to the

the upper, and upwards in the lower half of the plane; the broader planes are obſoletely and tranſverſely ſtriated. The acuminating planes are tranſverſely ſtriated, and (in the cryſtal from the Hartz) parallelly with the narrower planes of the priſm.

Externally the harmotome is ſhining, ſometimes ſplendent; its luſtre is between pearly and vitreous. Internally it is generally leſs ſhining.

Its fracture is uneven, or imperfectly conchoidal; the fragments are indeterminately angular, and rather ſharp edged.

It is generally tranſlucent only, eſpecially when of a yellowiſh or greyiſh-white, and ſmoke-grey colour; ſometimes, however, it is ſeen perfectly tranſparent and colourleſs. In ſome caſes, the degrees of tranſparency are different in different parts of the cryſtal.

It is moderately hard; ſcratches glaſs: the Scottiſh variety appear to be rather harder than that of the Hartz. It is brittle, and eaſily frangible. The ſpecific gravity of the white variety, according to Heyer, 2.353; according to Weſtrumb, 2.355; grey variety, 2.361, Weſtrumb; 2.333, Hauy.

Harmotome is ſaid by Reuſs to manifeſt the double refraction. When put on burning coals it emits, according to Hauy, a yellowiſh-green phoſphoreſcent light, which we could not obſerve.

Before the blow-pipe, this ſubſtance crumbles into minute particles, which, on urging the flame, are partly converted into ſmall glaſſy globules, but no ebullition appears to take place. With oxygen gas, the whole is fuſed into a whitiſh tranſlucid globule. With borax and mineral alkali, it melts under ebullition into a veſicular flag. The croſs ſtone is partly diſſolved in acids, but does not form a gelatine with them, like the zeolites. Other chemical characters mentioned in the books of mineralogy appear to be erroneous.

The analyſes given of this mineral by Heyer, Weſtrumb, Klaproth, and Teſſaërt, are very ſimilar in their reſults.

	Crucif. var. from Andreaſberg.		Dodec. var. from Oberſtein.	
Silica	49		47·5	
Barytes	18		16.0	
Alumine	16		19·5	
Water	15		13·5	
Loſs	2		3·5	
	100	Klaproth.	100.0	Teſſaërt.

The croſs-ſtone, or harmotome, has been hitherto found at Andreaſberg, on the Hartz; at Oberſtein, in the palatinate, and at Strontian, in Scotland. At Andreaſberg, particularly in the mines Abendröthe and Samſon, where it generally adopts the cruciform appearance, it always occurs aggregated (in druſes) in the middle of the vein, whence it may be conſidered as the neweſt of the minerals that compoſe thoſe veins. The principal accompanying minerals are calcareous ſpar and galena, ſparry iron-ſtone, quartz, brown blende, iron and copper pyrites, grey copper ore, and red ſilver. Mr. Von Buch did never find this mineral in company with barytes.

The variety found at Oberſtein, in the Palatinate, which is almoſt always the harmotome dodecaèdre of Hauy, is found in agate nodules, or cryſtallized rock cryſtal, or amethyſt: it is often yellowiſh and ferruginous. That of Strontian, in Argylethire, which is generally found in cryſtals, of the above varieties, Nos. 2 and 3, occur with calcareous ſpar, in a vein of lead, traverſing granite.

We underſtand, that a fine group of cryſtals of cruciform harmotome, *from Iceland*, is preſerved in the Imperial Cabinet of Vienna.

HARNAD, in *Geography*, a town of Hungary; 12 miles E.N.E. of Erlau.

Harnad *Nemeti*, a town of Hungary; 16 miles W. of Tokay.

HARNAS, a ſmall iſland on the W. ſide of the gulf of Bothnia. N. lat. 60° 40'. E. long. 17° 12'.

HARNESS, a complete armour, or the whole equipage and accoutrements of a cavalier heavily armed; as caſque, cuiraſs, &c.

The word is formed of the French *harnois*, which ſome derive from the Greek αρναξ, *a lamb's ſkin*, becauſe they anciently covered themſelves therewith. Du-Cange obſerves, that the word *harneſium* is uſed in the corrupt Latin in the ſame ſenſe, and that it comes from the High Dutch *harnas* or *harniſch*. Others derive it from the Italian *arneſe*; others from the Celtic *harnes, a cuiraſs*.

Under king Richard II. it was expreſsly forbidden all men to ride in harneſs with launcegays. (Vide ſtat. 7 Ric. II. cap. 13.) In the ſtatute 2 Hen. IV. cap. 14. harneſs ſeems to include all kinds of furniture for offence as well as defence, both of men and horſe; as ſwords, buckles for belts, girdles, &c.

Harness, in *Rural Economy*, a term ſignifying the traces, trappings, and furniture of the team horſe, or other animal that is employed in draught.

Harness-*galls*, in *Farriery*, hard lumps or ſwellings produced in the breaſts of horſes or other animals, by the preſſure and galling of the gears or trappings, particularly when they are wrought in rainy weather. In order to avoid this, the parts of the harneſs that reſt upon the animals ſhould be kept conſtantly well ſtuffed; and where there has happened any undue preſſure, the part ſhould be immediately bathed with cold vinegar-grounds, or a ſaturnine waſh. It is likewiſe a good practice to have the greaſe, ſweat, and dirt firſt well waſhed from the parts by means of ſoap and water.

Harness-*room*, a ſmall place contrived for the purpoſe of keeping the harneſs in. In order that it may be preſerved free from mouldineſs, it ſhould be perfectly dry, and placed as near to the ſtable as can be conveniently done.

HARNIT, or Arne, in *Geography*, a ſmall iſland in the Engliſh channel, about two miles from Guernſey, and one from Sark.

HARO, a walled town of Spain, in Old Caſtile, at the influx of the rivulet Tiron into the Ebro, in a fertile country, abounding in grain and fruits; containing 700 families, three pariſhes, and a convent; 12 miles N.E. of Burgos.

HARO, Harou, or *Harol*, in the *Norman Cuſtoms*.

Clamour de Haro is a cry or formula of invoking the aſſiſtance of juſtice againſt the violence of ſome offender, who, upon hearing of the word haro, is obliged to deſiſt, on pain of being ſeverely puniſhed for his outrage, and to go with the party before the judge.

The word is commonly derived of *ha* and *roul*, as being ſuppoſed an invocation of the ſovereign power, to aſſiſt the weak againſt the ſtrong, on occaſion of Raoul firſt duke of Normandy, about the year 912, who rendered himſelf venerable to his ſubjects by the ſeverity of his juſtice; ſo that they called on him, even after his death, when they ſuffered any oppreſſion. Some derive it from Harola, king of Denmark, who, in the year 826, was made grand conſervator of juſtice at Mentz; others from the Daniſh *aa raa*, *q. d.* help me, a cry raiſed by the Normans in flying from a king of

of Denmark, named Roux, who made himſelf duke of Normandy.

The letters of the French chancery have uſually this clauſe, *Non obſtant clâmeur de haro*, &c.

The haro had anciently ſuch vaſt power, that a poor man of the city of Caen, named Aſſelin, in virtue hereof, arreſted the corpſe of William the Conqueror, in the middle of the funeral proceſſion, till ſuch time as his ſon Henry had paid the value of the land in queſtion, which was that whereon the chapel was built where he was interred.

HAROLD I., in *Biography*, had the crown of England bequeathed to him by his father Canute in the year 1035. His countrymen, the Danes, maintained him in the ſucceſſion, though a ſtrong party, headed by earl Godwin, declared for Hardicanute. Harold gained over his moſt powerful enemy, Godwin, by promiſing to marry his daughter, and they united in contriving the murder of prince Alfred, ſon of Ethelred II. Queen Emma, his mother, was driven by this bloody action to take refuge in Flanders, and Harold took poſſeſſion of the whole kingdom without any ſerious reſiſtance. This, ſays the hiſtorian, is the only memorable action performed during a reign of four years by this prince, who gave ſo bad a ſpecimen of his character, and whoſe bodily accompliſhments alone are known to us by his appellation of Harefoot, which he acquired from his agility in running and walking. He died on the 14th of April 1039. Hume's Hiſt. vol. i.

HAROLD II., king of England, ſecond ſon of the famous Godwin, earl of Kent and Weſſex, was, in the elevation of that family under Edward the Confeſſor, made duke of Eaſt Anglia. After the death of his father in 1052, Harold ſucceeded him in his government and great offices; and, by his addreſs and inſinuating manners, gained the good will of Edward, and acquired many partizans among the nobility, ſo that, at the death of the king, his acceſſion to the crown was attended with little oppoſition, notwithſtanding the ſuperior claims of Edgar Atheling the legal heir, or the bequeſt of Edward in favour of William duke of Normandy. Scarcely, however, was he ſeated on the throne, when William ſent an embaſſy requiring Harold to reſign the crown to him, and on his refuſal, began to make preparations for an invaſion. In reply to this meſſage Harold ſaid, "That he had obtained the crown by the unanimous ſuffrages of the people, and ſhould prove himſelf totally unworthy of their favour, did he not ſtrenuouſly maintain thoſe national liberties, with whoſe protection they had entruſted him; and that the duke, if he made any attempt by force of arms, ſhould experience the power of an united nation conducted by a prince, who, ſenſible of the obligations impoſed on him, by his royal dignity, was determined that the ſame moment ſhould put a period to his life and government." William, in aid of his own exertions, inſtigated Torti, who had withdrawn in diſguſt to Flanders, to infeſt the northern coaſt of England in conjunction with the king of Norway. The united fleet of theſe chiefs ſailed up the Humber, and landed a numerous body of men, who were oppoſed by the earls of Northumberland and Mercia. An action enſued, but victory declared in favour of the invaders. Harold now collected an army, with which he gave the enemy battle at Stamford, and totally routed them. He got poſſeſſion of the Norwegian fleet, but generouſly permitted prince Olave with twenty ſhips to return to his own country. Scarcely were the rejoicings for this victory at an end, when the king received advice of the landing of the duke of Normandy with a powerful hoſt at Pevenſey in Suſſex. Thither Harold haſtened with all the troops he could muſter, and brought on, contrary to the advice of his officers, a general engagement at Haſtings, in which he was ſlain with an arrow, while combating with the greateſt bravery at the head of his men. Thus was gained by William duke of Normandy the great and deciſive victory of Haſtings, after a battle that was fought from morning till night, and which ſeemed worthy, by the heroic valour diſplayed by both armies, and by both commanders, to decide the fate of a mighty kingdom. The dead body of the king was brought to William, who generouſly reſtored it to his mother without ranſom; to himſelf the crown of England fell as the reward of his valour. Hume's Hiſt. vol. i. See HASTINGS.

HARON-ADAH, in *Geography*, a town of Perſia, in Irak; 30 miles W. of Kirmanſheh.

HARONIA, a town of the Arabian Irak; 45 N. of Bagdad.

HAROUE', a town of France, in the department of the Meurthe, and chief place of a canton, in the diſtrict of Lunéville; 13 miles S.W. of Lunéville. The place contains 640, and the canton 10,554 inhabitants, on a territory of 190 kiliometres, in 30 communes.

HAROUN, or AARON, AL RASHID, in *Biography*, caliph of the Saracens, the ſecond ſon of the caliph Mahadi, commander of the faithful, acquired great military renown as the leader of an expedition ſent by his father againſt the Greek empreſs Irene, in which he laid waſte ſeveral of the Aſiatic provinces of the empire, ſpread an alarm to Conſtantinople itſelf, and compelled the empreſs to purchaſe peace by a tribute. Five years after this expedition Haroun aſcended the throne of his father and elder brother, and became the moſt powerful and vigorous monarch of his race, illuſtrious in the Weſt, as the ally of Charlemagne, and familiar to moſt of our youthful readers, as the perpetual hero of the Arabian tales. The title of Al Raſhid, "The Juſt," was conferred on him as an illuſtrious example of that virtue, but his juſtice was ſullied by occaſional acts of violence and caprice. One of his beſt qualities was his love and encouragement of learning and ſcience, by which his court became the reſort of the moſt eminent literary characters of his time. He cauſed tranſlations to be made of many of the Greek and Latin authors into the Arabic, and he firſt rendered the works of the immortal Homer known to the Eaſtern poets. He paid great deference to the opinions of the doctors of his religion, and it is recorded that one Malec, the founder of an orthodox Mahometan ſect, having been ſent for by the caliph in order to inſtruct his ſons, and returning an anſwer, "that knowledge would not wait upon any perſon, but was itſelf to be waited upon," Haroun admitted the juſtice of the remark, and directed that his children ſhould attend him at the public ſchool. Haroun is ſaid to have invaded the Greek empire eight times. On the depoſition of Irene, the unnatural mother of Conſtantine, her ſucceſſor Nicephorus, in 802, refuſed to pay the uſual tribute to the caliph, and intimated, by a preſent of ſwords, delivered with an epiſtle, that he was ready to truſt his cauſe to the deciſion of arms. The caliph ordered the ſwords to be fixed together in the ground, and drawing his ſcymetar, cut them all aſunder with a ſtroke. He then dictated the following characteriſtic epiſtle: "In the name of the merciful God:" (moſt profane and wicked abuſe of holy language!) "Haroun al Raſhid, commander of the Faithful, to Nicephorus the Roman dog: I have read thy letter, O thou ſon of an unbelieving mother. Thou ſhalt not hear, thou ſhalt behold my reply." It was indeed written in characters of blood and fire on the plains of Phrygia. In ſe-

veral

veral campaigns Nicephorus was defeated in perſon by Haroun, great part of Aſia Minor was over-run by the arms of the Saracens, and Heraclea, a city on the Black ſea, was totally deſtroyed. Nicephorus was at length obliged to ſubmit to terms, and to admit even of an augmentation of tribute. In the courſe of theſe tranſactions, the ruin of the family of Barmacides gave a ſtriking example of the deſpotic rigour with which Haroun executed his purpoſes. The ſtory is too intereſting to be wholly omitted, and is as follows: "Yahia, the head of this family, had ſuperintended the caliph's education, and aſſiſted in his government. Of his four ſons, the eldeſt was a ſucceſsful general; Jaafar, the ſecond, was the caliph's vizier, and declared favourite, and diſtinguiſhed himſelf by his proficiency in polite literature; the two youngeſt were introduced into dignified ſtations. They were all educated in opulence, and had imbibed ſentiments worthy of their fortune. Their generoſity and munificence rendered them the darlings of all ranks of the people. Jaafar was ſo much the favourite of his maſter, that he could not endure to be without his company, and being equally attached to his own ſiſter Abbaſa, he thought fit to break through the Eaſtern formality of excluding unmarried females from the view of the other ſex. A mutual paſſion was the conſequence, which the caliph ſo far indulged as to permit a marriage between his ſiſter and the vizier, but with the cruel reſtriction of their abſtaining from the privileges of ſuch an union. Paſſion broke through this unjuſt prohibition: the conſequences, which were ſoon viſible, brought down the monarch's vengeance upon the head of Jaafar and his family. Jaafar was publicly executed; his venerable father impriſoned and probably aſſaſſinated, and the property of the whole race confiſcated. A decree was even made, forbidding, on pain of death, all mention of the names or actions of the Barmacides; but a grateful old man, who ventured openly to diſobey it, obtained his pardon and a remuneration from the caliph." Haroun was, as has been obſerved, the richeſt and moſt potent ſovereign of his time; he is ſaid to have ſent a ſplendid embaſſy to Charlemagne, which, among other preſents, brought a magnificent tent, a water-clock, an elephant and the keys of the holy ſepulchre at Jeruſalem, denoting permiſſion for European pilgrims to viſit it. The principal reſidence of this caliph was a favourite palace at Racca on the Euphrates. After his return from an expedition to quiet ſome commotions in Perſia, he was ſeized with great dejection of ſpirits, and an apprehenſion of death. From this he never quite recovered, and he died in a ſtate of deſpondence, in the year 808, at the age of forty-ſeven. The laſt command which he ever gave, was that of cutting to pieces, in his own preſence, the brother of a rebel who had taken up arms againſt his government. Nevertheleſs he is extolled for humanity; the tender mercies of ſuch men are truly cruel; Haroun was however capable of occaſionally exerciſing juſt and generous ſentiments. He could liſten to the complaint of a poor widow who had been pillaged by his troops, and who dared, in a paſſage of the Koran, to threaten the inattentive deſpot with the judgment of God and poſterity. The monarch pitying her misfortunes ordered full reſtitution to be made to her. Gibbon, vols. ix. x. Univer. Hiſt.

HAROWLY, in *Geography*, a town of Hindooſtan in the ſoubab of Delhi; 24 miles N.W. of Coel.

HARP, a muſical inſtrument of the ſtring kind, being of a triangular figure, and placed upright between the legs of the perſon who plays upon it.

Papias, and Du-Cange after him, will have the harp to have taken its name from the *Arpi*, a people of Italy, who were ſuppoſed the firſt that invented it; and from whom they ſay it was borrowed by other nations. Menage, &c. derives the word from the Latin *harpa*, and that from the German *herp*, or *harp*. Others bring it from the Latin *carpo*, becauſe touched or thrummed with the fingers. Dr. Hickes derives it from *harpa*, or *hearpa*, which ſignify the ſame thing; the firſt in the language of the Cimbri, the ſecond in that of the Anglo-Saxons. The Engliſh prieſt who wrote the life of St. Dunſtan, and who lived with him in the 10th century, ſays, cap. ii. n. 12. "Sumpſit ſecum ex more citharam ſuam, quam paterna lingua hearpam vocamus;" which intimates the word to be Anglo-Saxon.

There is ſome diverſity in the ſtructure of harps. That called the triple harp has ninety-ſeven ſtrings or chords, in three rows, extending from double C in the baſe, to double G in alt, which make five octaves: the middle row is for the ſemitones, and the two outſide rows are perfect uniſons. On the baſe ſide, which is played with the right hand, there are 36 ſtrings; on the treble ſide, 26; and in the middle-row, 35 ſtrings. There are two rows of pins or ſcrews on the right ſide, ſerving to keep the ſtrings tight in their holes, which are faſtened at the other end to three rows of pins on the upper ſide.

The harp, within the laſt forty years, has been in ſome degree improved, by the addition of eight ſtrings to the uniſon, *viz.* from E to double F in alt.

This inſtrument is ſtruck with the finger and thumb of both hands. Its muſic is much like that of the ſpinet, all its ſtrings going from ſemitone to ſemitone; whence ſome call it an *inverted ſpinet*.

It is capable of a much greater degree of perfection than the lute. The editor of the laſt folio edition of Chambers's Cyclopædia is indebted to Mr. Evans, a very celebrated performer on this inſtrument, for the above account of the ſtructure and compaſs of the Welſh harp. King David is uſually painted with a harp in his hands; but we have no teſtimony in all antiquity, that the Hebrew harp, which they call *chinnor*, was any thing like our's. On a Hebrew medal of Simon Maccabæus, we ſee two ſorts of muſical inſtruments; but they are both of them very different from our harp, and only conſiſt of three or four ſtrings. All authors agree that our harp is very different from the lyre, cithara, or barbiton, uſed among the Romans.

Fortunatus, lib. vii. carm. 8. witneſſes, that it was an inſtrument of the barbarians.

> "Romanuſque lyra, plaudat tibi barbarus harpa,
> Græcus Achilliacha, crotta Britanna canat."

The *crotta* is the *crwth* Latinized, in all probability an original Britiſh or Welſh inſtrument, as it is never mentioned in any claſſical author.

The harp is perhaps the moſt ancient inſtrument of which we know the uſe.

The Theban harp is an inſtrument, of which a beautiful drawing, by Mr. Bruce, and a deſcription, are inſerted in Burney's Hiſtory of Muſic, concerning the authenticity of which there were many doubts, and which were by no means removed by a pleaſantry of lord North, who ſaid "it was not a harp, it was a lyre;" yet in ſpite of ſcepticiſm and ſcoffers, the truth of Mr. Bruce's narrative has been brought into credit by ſir W. Jones, and lately fully aſcertained by the French invaders of Egypt, and by individual travellers of undoubted veracity.

We ſhall therefore inſert the account of this inſtrument, and of the ſituation in which it was found, in the traveller Bruce's own words.

"Behind the ruins of the Egyptain Thebes, and a very little to the N.W. of it, there is a great number of mountains hollowed

hollowed into monſtrous caverns, the ſepulchres, according to tradition, of the firſt kings of Thebes. The moſt conſiderable of theſe mountains, thus hollowed, contains a large ſarcophagus of granite, of which the lid only is broken.

"In the entrance of the paſſage which leads, ſloping gently down into the chamber where is the ſarcophagus, there are two pannels, one on each ſide: on that of the right is the figure of the *ſcarabæus Thebaicus*, ſuppoſed to have been the hieroglyphic of immortality. On the left, is the crocodile, fixed upon the apis with his teeth, and plunging him into the waves. Theſe are both moulded in baſſo relievo, in the ſtucco itſelf. This is a ſufficient indication of the grotto, to any one who may wiſh to examine it again. At the end of the paſſage, on the left hand, is the picture of a man playing upon the harp, painted in freſco, and quite entire.

"He is clad in a habit made like a ſhirt, ſuch as the women ſtill wear in Abyſſinia, and the men in Nubia. This ſeems to be white linen or muſlin, with narrow ſtripes of red. It reaches down to his ankles; his feet are without ſandals, and bare; his neck and arms are alſo bare; his looſe, wide ſleeves are gathered above his elbows; his head is cloſe ſhaved; he ſeems a corpulent man, of about 50 years of age, in colour rather of the darkeſt for an Egyptian.

"To gueſs by the detail of the figure, the painter ſhould have had about the ſame degree of merit with a good ſign-painter in Europe; yet he has repreſented the action of the muſician in a manner never to be miſtaken. His left hand ſeems employed in the upper part of the inſtrument among the notes in *alto*, as if in an *arpeggio*. While ſtooping forwards, he ſeems with his right hand to be beginning with the loweſt ſtring, and promiſing to aſcend with the moſt rapid execution. This action, ſo obviouſly rendered by an indifferent artiſt, ſhews that it was a common one in his time, or, in other words, that great hands were then frequent, and conſequently that muſic was well underſtood and diligently followed.

"If we allow the performer's ſtature to be about five feet ten inches, then we may compute the harp, in its extreme length, to be ſomething leſs than ſix feet and a half. It ſeems to ſupport itſelf in equilibrio on its foot, or baſe, and needs only the player's guidance to keep it ſteady. It has thirteen ſtrings. The length of theſe, and the force and liberty with which they are treated, ſhew that they are made in a very different manner from thoſe of the lyre.

"The inſtrument wants the fore-piece, or ſtay of the frame, oppoſite to the longeſt ſtring, which certainly muſt have improved the tone, and that deficiency muſt have rendered it very ſubject to go out of tune. The back part is the ſounding-board, compoſed of four thin pieces of wood, joined together in form of a cone, that is, growing wider towards the bottom; ſo that, as the length of the ſtring increaſes, the ſquare of the correſpondent ſpace, in the ſounding board, in which the tone is to undulate, always increaſes in proportion.

"Beſides that, the whole principles upon which the harp is conſtructed are rational and ingenious, the ornamental parts are likewiſe executed in the very beſt manner; the bottom and ſides of the frame ſeem to be vaneered, or inlaid, probably with ivory, tortoiſe ſhell, and mother-of-pearl, the ordinary produce of the neighbouring ſeas and deſerts. It would be even now impoſſible to finiſh an inſtrument with more taſte and elegance.

"Beſides the elegance of its outward form, we muſt obſerve, likewiſe, how near it approached to a perfect inſtrument; for it wanted only two ſtrings of having two complete octaves in compaſs. Whether theſe were intentionally omitted or not, we cannot now determine, as we have no idea of the muſic or taſte of that time; but if the harp be painted in the proportions in which it was made, it might be demonſtrated that it could ſcarce bear more than the thirteen ſtrings with which it was furniſhed. Indeed the croſs bar would break with the tenſion of the four longeſt, if they were made of the ſize and conſiſtence, and tuned to the pitch that our's are at preſent.

"I look upon this inſtrument, then, as the Theban harp, before and at the time of Seſoſtris, who adorned Thebes, and probably cauſed it to be painted there, as well as the other figures in the ſepulchre of his father, as a monument of the ſuperiority which Egypt had in muſic at that time, over all the barbarous nations that he had ſeen or conquered.

"Aſtronomy, and, we may imagine, the other arts, made a rapid progreſs at this period in Upper Egypt, and continued to do ſo for 50 years after, between which time, and the Perſian conqueſt, ſome cataſtrophe muſt have happened that reduced them to the loweſt ebb, which hiſtorians have miſtaken for their firſt original.

"We know about the time of Seſoſtris, if, as ſir Iſaac Newton ſuppoſes, this prince and Seſac were the ſame, that in Paleſtine the harp had only ten ſtrings; but as David, while he played upon it, both danced and ſung before the ark, it is plain that the inſtrument upon which he played could have been but of ſmall volume, we may ſuppoſe little exceeding in weight a guitar; though the origin of this harp was probably Egyptian, and from the days of Moſes it had been degenerating in ſize, that it might be more portable in the many peregrinations of the Iſraelites.

"The harp, that approaches the neareſt to this in antiquity, is repreſented upon a baſſo-relievo at Ptolemais, in the Cyrenaicum, a city built by Ptolemy Philadelphus, and it is there twice repreſented.

"It has fifteen ſtrings, or two complete octaves; but the adding theſe two notes has occaſioned likewiſe the addition of a fore-piece to ſuſtain the croſs bar above, ſo that its form is triangular; the extremity of the baſe is rounded into a ram's head, which ſeems to allude to its Theban original; and I ſhould imagine that this inſtrument is likewiſe Egyptian, as no harp with ſuch a number of ſtrings has ever been ſeen that I know of, in Grecian ſculpture." Hiſt. of Muſic, vol. i. p. 214.

Concerning the form of the harp of David we are utterly ignorant, though diſſertations have been written upon it, and Don Calmet has ventured to give it a form; but all we know of it is, that it was called *chinnor* in Hebrew, and the royal prophet himſelf frequently calls it the ten-ſtringed harp in the Pſalms.

The Welſh harp ſeems of very high antiquity in our iſland under the Druidical government. Before the invaſion of Julius Cæſar the Britons had muſic; and the bards, like the Levites among the Hebrews, were the ſacred muſicians; and we have the authority of venerable Bede for ſocial and domeſtic ſinging to the harp in the Saxon language, upon this iſland, at the beginning of the eighth century; though he himſelf wrote in Latin, the only language of the church and the learned then, and for many ages afterwards.

The above account of Welſh muſic was written and publiſhed in 1782, previous to the appearance of the "Muſical Relics of the Welſh Bards, by Mr. Edward Jones, Welſh Bard to His Royal Highneſs the Prince of Wales, in 1784," which is curious and entertaining; and being written by a native of Wales, and an eminent performer on the harp, we ſhall extract from this work Mr. Edward Jones's account of the muſical inſtruments of his country.

"The muſical inſtruments, anciently uſed in Wales, are as

as different from thoſe of other nations as their muſic and poetry.

"Theſe inſtruments are five in number, the *telyn*, or harp; the *crwth*; the *pibgorn*, or pipe; the *tabwrdd*, or tabret; and the *corn buelin*, cornet or bugle-horn.

"Notwithſtanding we find that the *telyn*, or Welſh harp, was always peculiar to our bards; though, probably, there was no difference betwixt the harp, when in its ancient primitive form, and the Grecian lyre; for Diodorus Siculus records that the Celtic bards played on inſtruments like lyres: ὀργάνων ταῖς λυραις ὁμοίων.

"In the time of the Welſh princes an hereditary harp was preſerved with great care and veneration in the houſehold of every prince and lord, to be beſtowed ſucceſſively on the bards of the family, and theſe were as indiſpenſible among the poſſeſſions of a gentleman as a coat of arms.

"The triple, or modern Welſh harp, has three rows of ſtrings; the two outſide rows are uniſon; the middle row the flats and ſharps. Its compaſs extends to five octaves. Some of its preſent appendages were probably the addition of the latter centuries. This celebrated inſtrument has been recently improved by the invention of pedals, which change it without freſh tuning into all the different keys, and have rendered it much leſs complicated and inconvenient by reducing it to a ſingle row of ſtrings."

This may, probably, not only improve the inſtruments in the principality, but the ſtyle of muſic and taſte of the country, which ſeem to have been totally confined to national tunes and vulgar variations. Mr. Jones himſelf, who, during many years, was the chief bard, and beſt performer on the *telyn*, an ancient Welſh harp, has quitted that inſtrument for the pedal harp, on account of the ſuperior facility with which all kinds of muſic for keyed inſtruments can be executed with as little difficulty as on a piano-forte; and it is, we ſuppoſe, in alluſion to the pedal harp, that Mr. Jones ſays, "in expreſſion and variety the harp has no rival, which every one will acknowledge who knows how the heart is ſoothed by its delicate and ſofter ſounds, as well as animated by its powerful and brilliant tones."

The triple harp ſeems to imply that there have been in Wales three ſeveral kinds of harps; the *ſingle harp*, with only one ſtring to each note; the *double harp*, with two; and the *triple harp*, with three ſtrings.

The harp was a favourite inſtrument with our Saxon anceſtors. All our hiſtorians relate the romantic ſtory of Alfred reconnoitring the Daniſh camp in the diſguiſe of a harper. Anlaff, and other Daniſh chiefs, played Athelſtan the ſame trick in the Saxon camp.

The harp of David, as well as that of Alfred, muſt have been of a different ſize and conſtruction from the triple Welſh harp to be portable; particularly that of David, when he danced before the ark.

Euſebius, indeed, calls it a lyre, and informs us that he carried it with him wherever he went, to conſole him in his affliction, and to ſing to it the praiſes of God.

Millico, when in this country, in 1774, accompanied himſelf in ſinging his elegant canzonets on a ſmall harp, which he ſlung over his ſhoulder like a guitar, with which, though of very different form, and open like a lyre, was equally portable.

The modern Iriſh harp is a ſingle inſtrument, ſtrung with metal ſtrings of braſs wire, nine in number, and calculated for mere melody, or a treble part. Carolan's tunes had no baſe to them originally, as we have been informed by the late Keane Fitzgerald, a native of Ireland, and a good judge of muſic, who had often ſeen and heard old Carolan perform. It was only after his deceaſe, in 1738, that his tunes were collected and ſet for the harpſichord, violin, and German flute, with a baſe, Dublin, folio, by his ſon, who publiſhed them in London by ſubſcription, in 1747.

Galilei, the father of the great mathematician Galileo, ſays that the Italians, who were in poſſeſſion of the harp before the time of Dante, had it from Ireland.

According to Mr. Walker, in his "Hiſtorical Account of the Iriſh Bards," the Iriſh have four different ſpecies of harp: 1ſt. The *Clar-ſch*, or *clar-ſoach*, commonly denominated the Iriſh harp.

2d. *Keirnine*, a ſpecies of dulcimer, (not a ſackbut, a double curtle, or baſſoon, which are wind inſtruments.)

3d. The *Cionu cruit*, of ten ſtrings, a kind of guitar.

4th. The *Greamthine cruit*, the *crwth* of the Welſh.

Whether the Welſh had their muſic from Ireland, according to Giraldus Cambrenſis, or the Iriſh had theirs from the Cambro-Britons, we ſhall not attempt to determine, but ſhall leave St. David and St. Patrick, and their champions Jones and Walker, patriotically to diſpute the point.

In the late laborious Mr. Strutt's "Saxon Antiquities," vol. I. we have repreſentations of antique harps, one with nine ſtrings, and another with eleven, copied from illuminated MSS. in the Britiſh Muſeum; and a lyre of four ſtrings of the middle ages, "beaten with a ſmall inſtrument for that purpoſe;" meaning a *plectrum*.

The early muſical inſtruments of all countries, like thoſe of Greece and Rome, are of ſmall compaſs.

> "Tibia non, et nunc, orichalco juncta tubæque
> Æmula; ſed tenuis, ſimplexque foramine vacuo
> Aſpirare."

In all our inquiries we can obtain no ſatisfactory account of the time when, and on what occaſion, the harp was aſſumed in the arms of Ireland. The learned Mr. O'Halleran ſays it was by order of Henry II., and Mr. Ledwich by that of Henry VIII. (Walker's Iriſh Bards); but neither of theſe gentlemen aſſigns a reaſon for it, or gives any authority for his aſſertions.

In days of chivalry, the harp paſſed for the moſt noble and majeſtic of inſtruments, and on this account the romancers place it in the hands of their greateſt heroes, as the ancient Greek bards did the lyre.

This inſtrument was in ſuch general favour, that an old poet has made it the ſubject of a poem called "Le Dict de la Harpe," "The Ditty, or Poem, upon the Harp," and praiſes it as an inſtrument too good to be profaned in taverns or places of debauchery, ſaying that it ſhould be uſed by knights, eſquires, clerkes, perſons of rank, and ladies with plump and beautiful hands; and that its courteous and gentle ſounds ſhould be heard only by the elegant and good.

It had twenty-five ſtrings, to each of which the poet gives an allegorical name: calling one *liberality*, another *wealth*, a third *politeneſs*, a fourth *youth*, &c. applying all theſe qualities to his miſtreſs, and comparing her to the harp.

HARP, *Bell*, a muſical inſtrument of the ſtring kind, thus called from its being ſwung about by thoſe who play upon it like a bell. It is about three feet long; its ſtrings are of braſs or ſteel wire, fixed at one end, and ſtretched acroſs the ſound board, by ſcrews fixed at the other end. It comprehends four octaves, and the ſtrings are ſtruck with the thumbs, the right hand playing the treble, and the left the baſe; and,

in order to draw the ſounds the clearer, the thumbs are armed with a little wire pin.

HARP, *Silver*, or *Prize Harp*, at the *Eiſteddfod*, or aſſion of the bards and minſtrels, appointed in the ninth year of queen Elizabeth, at Caerwys, in North Wales. (Pennant's Tour in North Wales 1773, printed 1778.) This was reviving an ancient cuſtom in the principality, as the Welſh hiſtorians and annaliſts inform us that Gruffidd ap Conan, prince of Wales, eſtabliſhed a congreſs or meeting of maſters of muſic about the year 1100, who underwent a public examination for degrees in their art, and for prizes, the chief of which was a ſilver harp, with nine ſtrings, worn by the victor as a badge of honour.

As one of theſe prize harps is ſtill preſerved in the curious collection of Cambro-Britiſh antiquities of the Moſtyn family, and another in Dr. Burney's collection, we ſhall give an exact repreſentation of it in one of our plates of muſical inſtruments.

HARP, *Æolus's*. See ÆOLUS's *Harp*.

HARP, in *Mythology*, is the ſymbol of Apollo.

HARP, in the *Manege*. See GRAPPLE.

HARP *Iſland*, in *Geography*, an iſland in the South Paciſic ocean, ſo called from its figure by M. Bougainville, in 1768. It was inhabited. S. lat. 18°. W. long. 140°.

HARPAGE, in *Ornithology*. See HARPY.

HARPAGIUS, in *Antiquity*. See ARPAGIUS.

HARPALUS, in *Biography*, a celebrated Greek aſtronomer, who flouriſhed about 480 years before the Chriſtian era, invented a new cycle which went by his name, and which was followed, till Meton, the ſon of Pauſanias, proved it to be erroneous, and publiſhed his own, or the cycle of nineteen years, which is ſtill in uſe, and known under the name of the "golden number." Moreri.

HARPATH, in *Geography*, a river of America, in Teneſſee, which, after a N.W. courſe of about 40 miles, diſcharges itſelf into Cumberland river; 19 miles N.W. of Naſhville.

HARPE, JEAN FRANÇOIS DE LA, in *Biography*, a celebrated dramatiſt and critic, was born at Paris, November 20th, 1739. By the death of his father while he was young, the ſon was left in extreme poverty. Exhibiting, however, genius and talents above the common order, he was patronized by M. Aſſelin, principal of the college of Harcourt, who admitted him as one of his pupils. La Harpe commenced his literary career by poems called heroides, which were at that time much in faſhion. In this ſtyle of writing there were ſeveral candidates for popular applauſe, but the public ſuffrages were divided between La Harpe and Dorat. By men of judgment and real taſte the performance of La Harpe was deemed the ſuperior. He now put in a claim for the honours of the academy, and thoſe of the theatre. He obtained the firſt by his eulogy on Charles V., and ſucceſs in this inſtance led him to increaſe his reputation by eulogies on Fenelon, Catinat, and Racine: the latter was eſteemed his *chef d'œuvre* in this kind of compoſitions. As a writer for the ſtage, we have his Warwick, Coriolanus, Philoctetes, Barmecides, Johanna of Naples, Menzicoff, and others. He wrote alſo a comedy for the inauguration of the new French theatre, entitled "Moliere at the New Theatre," which is diſtinguiſhed for its neatneſs and gaiety. The principal work of M. de la Harpe, is his "Cours de Litterature, Ancienne et Moderne," which entitles the author to a high place in the learned world. By ſome of his contemporaries he is ranked with Quintilian: in comparing him with Marmontel, it is ſaid by a good judge, "That the career of La Harpe is much more vaſt and brilliant. He not only labours to give to perſons of no great knowledge competent information on the topics of his work, but arreſts the attention of the moſt learned. In his plans, the outline of which alone announces an immenſe ſtock of ſcience and learning, he embraces all ages in which literature has flouriſhed. Every celebrated work is analyzed and diſcuſſed. The beauties of the ſeveral writers are happily diſplayed, and their faults pointed out with all the ability of the moſt lively and ſound criticiſm. That which diſtinguiſhes La Harpe from other moderns who have treated of literarature is, that he always aſſumes the tone of the work he criticiſes, a merit which we find in none of the ancients except Cicero, Quintilian, and Longinus. If he ſpeaks of the Iliad, we behold him borrow all the rich colours of the father of poetry to decorate his diſcourſe. If he treats of Demoſthenes and Cicero, all the great intereſts of Athens and Rome are reproduced under his pen. If Tacitus is his theme, we are inſtantly tranſported to the age of the emperors: we enter into all the myſtery of the dark policy of Tiberius, and tremble at the ſight of Nero." The only regret on this ſubject is that the author did not live to finiſh his courſe of inſtruction. Under the tyranny of Robeſpierre La Harpe was thrown into priſon, where he long remained between the living and the dead, uncertain each hour to which he ſhould belong. He had, however, the happineſs to be forgotten in his dungeon, from which he was liberated ſhortly after the death of the monſter who placed him there. A new ſtorm aroſe, and La Harpe was driven to ſeek an aſylum in a ſpot impenetrable to all but faithful friendſhip. Being in this ſituation deprived of exerciſe, his health rapidly declined, and in February 1803 he died, in the 65th year of his age. La Harpe had, like many of his countrymen, been a freethinker, treating the Chriſtian ſyſtem with contempt, but during his impriſonment he had an opportunity of re-conſidering the ſubject, the reſult of which was, that he became a firm believer, and determined to conſecrate the remainder of his days to the ſervice of that religion which he had heretofore contemned; and at the Lyceum, and in the preſence of a numerous audience, he boldly retracted his errors.

HARPE, in *Natural Hiſtory*, the name of a kind of ſhell-fiſh of very great beauty. It is of the genus of the dolium or concha globoſa. See LYRA.

HARPE *a Pedal*, Fr., in *Muſic*, a harp with pedals to produce the half notes.

Before the invention of pedals, the whole range of ſounds in the double and treble harps on the continent, had been reduced to the diatonic ſcale, with a ſingle ſtring to each note; the ſemitones being produced by braſs rings with the left hand, at the top of the inſtrument, which were both difficult to get at and diſagreeable to hear, from the noiſe, which by a ſudden motion of the hand, they occaſioned.

It was ſome time after this expedient was put in practice, before the ſecret of producing the half notes by pedals was diſcovered.

In 1772, we firſt heard the pedal harp at Paris and Bruſſels, where the inſtrument was conſtructed of an elegant form, and beautifully ornamented. Its tone was ſweet, diſtinct, and capable of the moſt minute ſhades of piano, and the moſt touching expreſſions. Among all the muſical inſtruments in uſe, there is no one more becoming to a female figure. And by means of the pedals for the half notes, it is leſs cumbrous and unwieldy, and more eaſy of performance than our double Welſh harp.

The compaſs of theſe harps of new conſtruction was from double B b in the baſe, to F in altiſſimo.

This

This method of producing the half-notes on the harp by pedals, which has rendered it a female inſtrument, was invented at Bruſſels about the year 1757, by M. Simon, who ſtill reſided in that city in 1772. It is an ingenious and uſeful contrivance, in more reſpects than one; for by reducing the number of ſtrings, the tone of thoſe that remain is improved: as it is well known that the leſs an inſtrument is loaded, the more freely it vibrates.

We ſhall not attempt to inſtruct our readers how to apply theſe pedals to the harp, or to explain their operation; the mechaniſm is too complicated to be taught by verbal inſtruction. To make a watch by a receipt would be the deareſt way of purchaſing it.

HARPEGEMENT, Fr. See ARPEGGIO.

HARPEGGIATO, Ital. See ARPEGGIO.

HARPERS, BRITISH. Theſe we are certain were famous long before the conqueſt, and the bounty of our firſt Norman ſovereign to his joculator or bard is recorded in Doomſday-book; (Glouceſterſcire. Berdic, Joculator Regis, habet iii. Villas et ibi v. car. nil redd. See Anſtis, Ord. Gart. ii. 304.) Nor ſhould that of Henry III. be forgotten, who, in the thirty-ſixth year of his reign, not only gave forty ſhillings and a pipe of wine to Richard, his harper, but another pipe of wine to Beatrice, the harper's wife; (Rot. Pip. an. 36 Hen. III. Et in uno dolio vini empto et dato Magiſtro Ricardo Cithariſtæ Regis, xl. ſol. per. Br. Reg. Et in uno dolio empto et dato Beatrici uxori ejuſdem Ricardi.) All our moſt ancient poems, whatever was their length, were ſung to the harp on Sundays and on public feſtivals. See Warton's Hiſt. Engl. Poetry, vol. i. p. 12. 18. and elſewhere.

HARPER'S *Ferry*, in *Geography*, a poſt-town of America, in Berkeley county, Virginia; 65 miles from Waſhington. Here is an armoury, and a manufactory of muſkets and bayonets.

HARPERSFIELD, a poſt-town of America, in Delaware county, New York; 32 miles S.E. of Cooper's town; containing 1013 inhabitants.

HARPIES, ΑΡΠΥΙΑΙ, *Harpyiæ*, in *Antiquity*, a rapacious impure ſort of monſters, of the bird kind, mentioned among the poets.

They are repreſented with wings, ears like bears, bodies like vultures, faces like women, and feet and hands hooked like the talons of birds of prey. See Virgil, Æneid. lib. iii. who gives a deſcription of them, and ſeems to claſs them with the Furies.

The ancients looked on the Harpies as a ſort of genii or demons. Some make them the daughters of Tellus and Oceanus, the *Earth* and *Ocean*; whence, ſays Servius, it is, that they inhabit an iſland, half on land and half in water. Valerius Flaccus makes them the daughters of Typhon; thus Celœno ſpeaks "Vobis Furiarum ego maxima pando." There were three Harpies, Aello, Ocypete, and Celœno, which laſt Homer calls *Podargæ*. Heſiod, in his Theogony, ver. 267, only reckons two, Aello and Ocypete, and makes them the daughters of Thaumas and Electra, affirming that they had wings, and went with the rapidity of the wind. Zephyrus begat of them Balius and Xanthius, Achilles's horſes. Pherecydes relates, that the Boreades expelled them from the Ægean and Sicilian ſeas, and purſued them as far as the iſlands, which he calls Plotæ, and Homer Calynæ; and which have ſince been called the Strophades.

Voſſius, De Idolol. lib. iii. cap. 99. p. 63. thinks that what the ancients have related of the Harpies, agrees to no other birds ſo well as the bats found in the territories of Darien in South America. Theſe animals kill not only birds, but dogs and cats, and prove very troubleſome to men by their peckings. But the ancients, as the ſame Voſſius obſerves, knew nothing of theſe birds. By the Harpies, therefore, he thinks they could mean nothing elſe but the winds; and that it was on this account they were made daughters of Electra, the daughter of Oceanus. Such is the opinion of the ſcholiaſts of Apollonius, Heſiod, and Euſtathius. Their names, Aello, Ocypete, Celœno, are ſuppoſed to ſuggeſt a farther argument of this. Le Clerc (Bibliotheque Univ. tom. i. p. 248.) conjectures that the Harpies were locuſts; which, after they had laid waſte Bithynia and Paphlagonia, were driven by a north wind into the Ionian ſea, where they periſhed, and hence originated the fable, that the ſons of Boreas had put them to flight. Some have ſuppoſed that they were the daughters of Phineus, who treated the Argonauts hoſpitably, and ſhewed them the way to Colchis, and that they ruined their father by their debauchery. The abbé Banier conjectures that antiquity deſigned to figure by theſe pretended monſters, ſome turbulent and miſchievous neighbours, or ſome pirates who made frequent deſcents upon the dominions of Phineus; and that he equipped a ſhip, and having put them to flight, purſued them to the Strophades iſles, where they periſhed.

Mr. Bryant ſuppoſes that the Harpies were a college of prieſts in Bithynia, who, on account of their repeated acts of violence and cruelty, were driven out of the country: their temple was called Arpi, and the environs Arpiai, whence the Grecians formed Ἅρπυιαι; and he obſerves farther, that Harpyia, Ἅρπυια, was certainly of old the name of a place. Anal. of Anc. Mythol. vol. ii. p. 42.

HARPINEER, or HARPOONEER, an engineer or fiſherman, who manages and throws the harping-iron in the whale-fiſhing. See *Whale* FISHERY.

HARPING-IRON, HARPAGO, *Harpoon*, a ſort of dart or ſpear, faſtened to a line, wherewith they catch whales and other large fiſh, as ſturgeons, &c.

The harping-iron is a large javelin of forged iron, generally about twenty ounces in weight, and about two feet long, with a ſharp, cutting, triangular point, barbed like that of an arrow. At the upper end is engraven the harpineer's name, near a ring to which the line is faſtened, which they let down as ſoon as the fiſh is ſtruck, to give him room to dive, &c. See *Whale* FISHERY.

The harpoon cannot be ſtruck with certainty at any conſiderable diſtance; ſo that unleſs the harpooner is within a yard of a whale, or directly above, this inſtrument cannot be uſed with any great ſucceſs. In the year 1731, a new ſort of gun was invented for ſhooting the harpoons into the bodies of whales at a greater diſtance than they could be thrown by hand, and this was uſed for two or three ſeaſons with ſome ſucceſs: but farther experience has proved the inutility of this contrivance. It was afterwards propoſed to ſubſtitute the ancient baliſta in the room of the gun; but the ſcheme, we believe, terminated in mere ſpeculation. Phil. Tranſ. vol. xlvii. p. 429.

HARPINGS, pieces of oak from four to ſix inches deep, trimmed to the ſhape of the ſhip at the bow and after part lengthwiſe, confining the timbers together before the plank is brought on. See this article fully explained in SHIP-BUILDING.

HARPINGS, *Cat*. See CAT *Harpings*.

HARPLE, or MARPLE, in *Geography*, a townſhip of Delaware county, Pennſylvania, containing 761 inhabitants.

HARPOCRATES, in *Mythology*, the ſon of Iſis and Oſiris. This is an Ægyptian Deity, whoſe diſtinguiſhing attribute is, that he is repreſented with his fingers applied to his mouth, denoting that he is the God of ſilence. The ſtatue of this idol was fixed in the entrance of moſt of the Egyptian

Egyptian temples, and he was commonly exhibited under the figure of a young man naked, crowned with an Egyptian mitre, holding in one hand a cornucopia, and in the other the flower of lotus, and ſometimes bearing a quiver. As Harpocrates was always repreſented with his finger upon his lips, the Egyptians intended by this attitude to denote, that the gods were to be adored in ſilence, or as Plutarch intimates, that they who knew theſe gods were not to ſpeak of them raſhly. There was even a law, according to Varro, which forbade any, under pain of death, to ſay that Serapis had been a mortal man; and as in the temples of Iſis there was an idol, that is, an Harpocrates putting the finger to his mouth, Varro was of opinion, that he was placed there to recommend ſilence as to that article. Harpocrates and Orus, or Horus, are ſuppoſed to have been the ſame perſon; and as the latter was among the Egyptians the ſymbol of the ſun, the latter is thought to have repreſented the ſame perſon. Accordingly he is ſometimes exhibited under the figure of a child, riſing out of the flower of the lotus, with his head encompaſſed by rays, and with a whip in his hand, to denote the riſing ſun.

HARPOCRATIANS, a ſect of heretics mentioned by Celſus, and the ſame with CARPOCRATIANS.

HARPOCRATION, in *Biography*, a rhetorician of Alexandria, flouriſhed in the fourth century. He wrote a "Lexicon of ten Greek Orators," in which he treats of magiſtrates, courts of juſtice, forms of pleading, diſtricts, men in public ſtations, &c. of Attica. There have been ſeveral modern editions of this work. Moreri.

HARPONELLY, in *Geography*, a circar of Hindooſtan, in Myſore, bounded on the N. by Sanore, on the E. by Chitteldroog, on the S. by Bednore, and on the W. by Canara; about 120 miles in length, and 60 in breadth. After the death of Tippoo, it was ſurrendered to the Mahrattas.—Alſo, the capital of the circar of the ſame name; 65 miles N.N.E. of Bednore. N. lat. 14 40'. E. long. 75 28'.

HARPSICHORD, in *Muſic*, a keyed inſtrument of the ſtring kind. It is in fact a horizontal harp, which inſtrument, if ſtrung with wire, and played with a quill like a mandoline, would have the ſame effect. Its tone is produced by jacks quilled with crow or raven quills. (See JACK.) A ſingle harpſichord of two uniſons and one ſet of keys, was, in effect, a double SPINET or VIRGINAL.

But a *double* harpſichord uſed to have two ſets of keys and three ſtrings, two uniſons and an octave to each note. Merlin, we believe, was the firſt who changed the octave ſtop to a third uniſon, about the year 1770, which rendered the inſtrument equally powerful, and leſs ſubject to go out of tune; the octave ſtop being ſo much affected by the leaſt change in the temperature of the air, that it almoſt inſtantly diſcovered when there was a change in the wind.

Beſides arming the tongues of the jacks with crow or raven quills, ſeveral other means were tried by which to produce a ſofter tone, and to be more durable; as the quilling a harpſichord with three ſtops was nearly a day's work: leather, ivory, and other elaſtic ſubſtances were tried, but what they gained in ſweetneſs, was loſt in ſpirit.

The beſt harpſichords of the eighteenth century, were made by Ruckers of Antwerp, and his family; Geronimo of Florence, Couſhette, Tabel, and Kirkman, and Shudi, Tabel's foremen.

However, in the beginning of the laſt century, hammer harpſichords were invented at Florence, of which there is a deſcription in the Giornale d'Italia, 1711. The invention made but a ſlow progreſs. The firſt that was brought to England was made by an Engliſh monk at Rome, Father Wood, for an Engliſh friend (the late Samuel Criſp, eſq. of Cheſington, author of Virginia, a tragedy, and) a man of learning, and of exquiſite taſte in all the fine arts.

The tone of this inſtrument was ſo ſuperior to that produced by quills, with the additional power of producing all the ſhades of *piano* and *forte* by the finger, that though the touch and mechaniſm were ſo imperfect that nothing quick could be executed upon it, yet the dead march in Saul, and other ſolemn and pathetic ſtrains, when executed with taſte and feeling by a maſter a little accuſtomed to the touch, excited equal wonder and delight to the hearers. Fulk Greville, eſq. purchaſed this inſtrument of Mr. Criſp for 100 guineas, and it remained *unique* in this country for ſeveral years, till Plenius, the maker of the lyrichord, tuned by weights, and the tone produced by wheels, made a piano-forte in imitation of that of Mr. Greville. Of this inſtrument the touch was better, but the tone very much inferior.

Backers, a harpſichord maker of the ſecond rank, conſtructed ſeveral piano-fortes, and improved the mechaniſm in ſome particulars, but the tone, with all the delicacy of Schroeter's touch, loſt the ſpirit of the harpſichord, and gained nothing in ſweetneſs.

After the arrival of John Chr. Bach in this country, and the eſtabliſhment of his concert, in conjunction with Abel, all the harpſichord makers tried their mechanical powers at piano-fortes; but the firſt attempts were always on the large ſize, till Zumpé, a German, who had long worked under Shudi, conſtructed ſmall piano-fortes of the ſhape and ſize of the virginal, of which the tone was very ſweet, and the touch, with a little uſe, equal to any degree of rapidity. Theſe, from their low price, and the convenience of their form, as well as power of expreſſion, ſuddenly grew into ſuch favour, that there was ſcarcely a houſe in the kingdom where a keyed-inſtrument had ever had admiſſion, but was ſupplied with one of Zumpé's piano-fortes, for which there was nearly as great a call in France as in England. In ſhort, he could not make them faſt enough to gratify the craving of the public. Pohlman, whoſe inſtruments were very inferior in tone, fabricated an almoſt infinite number for ſuch as Zumpé was unable to ſupply. Large piano-fortes afterwards receiving great improvement in the mechaniſm by Merlin, and in the tone by Broadwood and Stoddard, the harſh ſcratching of the quills of a harpſichord can now no longer be borne. During the laſt century, the eminent Italian performers on, and compoſers for the harpſichord, were Domenico Scarlatti, Alberti, Paradies, and Clementi. Among our great organ players, Kelway, Dr. Worgan, and Mr. C. Burney acquired great reputation by their performance on the harpſichord, as did Mrs. Wynne, Miſs Beſt, and Mrs. C. Burney. In France, Couperin, Jaig, Balbaſtre, Schobert at Straſbourg, and in Germany Emanuel Bach and innumerable others. Dr. Smith, for applying his ſyſtem of equal harmony to practice, added eight ſtrings to the common harpſichord; but the inconvenience of moving the ſliders by the hand is remedied by Dr. Loeſchman's patent piano-fortes and organs, in which the ſliders are moved by pedals, and the ſcale is alſo extended to 24 notes in the octave.

HARPY, in *Ornithology*, the trivial name of the Gmelinian FALCO *Rufus*; called alſo *Harpage*.

HARQUEBUSS, in our *Ancient Statutes*, called alſo *arquebuſe*, *haquebut*, or *hagbut*, is a hand-gun, or a fire-arm of a proper length, &c. to be borne in the arm.

The word is formed of the French *arquebuſe*; and that from the Italian *arcobuſio*, or *arco abuſo*, of *arco*, *a bow*, and *buſio*, *a hole*; on account of the touch-hole, at which the powder is put to prime it, and that it ſucceeded to the bows of the ancients. The harquebuſs is properly a fire-arm, of the ordinary length of a muſket or fowling-piece; cocked uſually with a wheel-

wheel. Hanzelet deſcribes its legitimate length to be forty calibres; and the weight of its ball one ounce ſeven eighths; its charge of powder as much.

There is alſo a larger kind, called *harquebuſs a croc*, much of the nature of our blunderbuſſes, uſed in war for the defence of places, being uſually reſted on ſomething when diſcharged. The firſt time theſe inſtruments were ſeen, was in the imperial army of Bourbon, who drove Bonnivet out of the ſtate of Milan: they were ſo big and heavy, that there were two men to carry them. They are now little uſed except in ſome old caſtles, and by the French in ſome of their garriſons.

HAIRA, in *Geography*, a town of Perſia, in the province of Segeſtan; 105 miles W.N.W. of Zareng.

HARRAD, a town of Arabia Felix, in the province of Yemen; 24 miles S. of Abu-Ariſch.

HARRIER, in *Ornithology*, called alſo the hen-harrier, the Falco *cyaneus*.

Harrier, or *Leverarius*, a kind of hound, called in Latin *fagax*, from his tracing or chaſing by foot; being endowed with an admirable gift of ſmelling, and alſo very bold in the purſuit of his game.

There are ſeveral kinds, all differing in their ſervices; being for the hare, fox, wolf, hart, buck, badger, otter, polecat, weaſel, or coney; ſome, in fine, for one game, ſome for another, &c. See Dog and Hunting.

HARRINGTON, James, in *Biography*, a celebrated political writer, was born at Upton, in Northamptonſhire, in 1611. He was naturally of a ſerious and very ſtudious diſpoſition, and was diſtinguiſhed, in early life, for habits and manners different from thoſe of moſt other children. He ſtudied at Trinity college, Oxford, of which he was admitted fellow commoner in 1629. On the death of his father, he quitted the univerſity, after a reſidence of three years, and travelled into foreign countries. In the Netherlands he entered as a volunteer. He frequented ſeveral courts on the continent, and at Rome diſtinguiſhed himſelf, by refuſing, at a public ceremonial, to kiſs the pope's toe; when blamed, in the preſence of his own king, for this want of attention to foreign cuſtoms, he replied, that having had the honour of kiſſing his majeſty's *hand*, he thought it beneath him to kiſs the *toe* of any other ſovereign. In the civil wars, he took no very active part, but his principles led him to ſide with the parliament. In 1647, he was, at the recommendation of the parliamentary commiſſioners, nominated by the king as one of the grooms of his bed-chamber, upon the diſmiſſion of ſome of his old ſervants. The great learning and genius of Harrington won ſo much upon the king, that he was accuſtomed to converſe more with him than his other attendants; and the royal condeſcenſion and familiarity had ſuch an effect upon the mind of Harrington, that he uſed every effort to accommodate the differences between the king and parliament. His commiſeration for the depreſſed circumſtances of Charles was the cauſe of his being diſmiſſed from his office: at this circumſtance, the concern of both parties was manifeſt, and it is ſaid, that the king gave him a token of his affection before his execution. That event, which Harrington had done all in his power to avert, gave a ſevere ſhock to his feelings, and he never forbore to ſpeak of it with extreme regret, and with commiſeration of the unfortunate prince. He was too much of a republican, and underſtood too well his own principles, to be pleaſed with the conduct of Cromwell, and during the protectorate he paſſed his time in retirement, chiefly occupied in the compoſition of that work by which he is chiefly known, *viz.* "The Oceana." Cromwell cauſed the performance to be ſeized at the preſs, but, through the interceſſion of the protector's daughter, it was reſtored, and given to the public in 1656. The Oceana, ſays Mr. Hume, vol. vii. p. 347, was well adapted to that age, when the plans of imaginary republics were the daily ſubjects of debate and converſation; and even in our time, it is juſtly admired as a work of genius and invention; the idea, however, of a perfect and immortal commonwealth, will always be found as chimerical as that of a perfect and immortal man. The ſtyle of this author wants eaſe and fluency, but the good matter which his work contains makes compenſation. Another work of this author, was entitled "The Art of Law-giving." To propagate the principles of republicaniſm, he inſtituted a kind of debating club, called the "Rota," which met at a tavern for diſcuſſion, and frequently tried the ſenſe of the public on political queſtions, by a ballot. (See Rota.) At the reſtoration, Harrington retired to privacy, in which he ſtill buſied himſelf in political ſchemes, and was viſited by many, ſome with a view of profiting by his converſation, and others, as it afterwards appeared, in the deteſtable character of ſpies on his private thoughts. In 1661, he was arreſted, on the accuſation of ſome of thoſe wretches, and committed priſoner to the Tower, for "treaſonable practices," a convenient phraſe, which may mean any thing and nothing. His impriſonment was, however, of the ſevereſt kind, and the hardſhips which he underwent brought on a mental derangement, of which he never completely recovered. He died in the year 1677, and was buried in St. Margaret's church, Weſtminſter. He was a man of extenſive knowledge and conſiderable abilities. Of his writings, few are ever looked into by readers of the preſent day, except his "Oceana," which was a kind of political romance, exhibiting an ideal republic, formed upon a model, as he deemed it, moſt favourable to public liberty. His works were collected by Toland, and printed in one vol. fol. in the year 1700, but a more complete edition of them was printed in 1737, by Dr. Birch. Biog. Brit. Hume's Hiſt.

Harrington, *Sir* John, was born about the year 1561, at Kelſton, near Bath. His father had been impriſoned, in the time of queen Mary, for holding a correſpondence with the princeſs Elizabeth, who, when ſhe came to the throne, ſhewed her regard for his attachment to her in misfortune, by ſtanding god-mother to his ſon. The youth, when at an age fit for it, was ſent to Eton ſchool, and from thence he removed to Cambridge. He was firſt known to the public by a tranſlation of Arioſto's Orlando Furioſo, which gave him a conſiderable reputation as a poet. After his death, his "Epigrams" were publiſhed in four books: and ſome of his other writings were printed about 40 years ago, by Henry Harrington, of Queen's college, Cambridge, in connection with pieces by different perſons, under the title of Nugæ Antiquæ. In public life Mr. Harrington went out with the earl of Eſſex to Ireland in 1599, and received from him the honour of knighthood: and by king James he was made knight of the Bath. He died in 1612, and had previouſly ſketched a plan for the hiſtory of his own times. Biog. Brit.

Harrington, in *Geography*, a town of America, Waſhington county, Maine, at the head of Narraguagus bay, containing 298 inhabitants.—Alſo, a townſhip in Bergen county, New Jerſey.

HARRIORPOUR, a town of Hindooſtan, and capital of the circar of Mohurbunga, in Oriſſa; 105 miles W.S.W. of Calcutta. N. lat. 21° 53'. E. long. 86 13'.—Alſo, a town of Hindooſtan, in Oude; 26 miles W. of Fyzabad.—Alſo, a town of Mocampour; 15 miles S. of Mocampour.

HARRIOT, Thomas, in *Biography*, was born at Oxford, in

in the year 1560, where he was educated; and at St. Mary's hall he was admitted to the degree of B. A. in the year 1579. At this period he had acquired ſo high a reputation for mathematical knowledge, that he was appointed preceptor to ſir Walter Raleigh. He was not long in this capacity, but during the time he had acquired the eſteem and confidence of his pupil ſo completely, that we find him ſent out by him with the colony under ſir Richard Grenville to Virginia, in the year 1585, as a perſon qualified to prepare the way for ſettling it. Mr. Harriot remained in that country about a year, diligently employed in ſurveying it, and in obſerving the nature of its productions, as well as the cuſtoms and manners of its inhabitants. Upon his return to England he publiſhed "A brief and true report of the new-found land of Virginia, of the commodities there found and to be raiſed," &c. 4to. This work was printed in the year 1590, and about the ſame time the author was introduced by ſir Walter to the acquaintance of Hugh Percy, earl of Northumberland, who granted him a penſion of 300*l.* per annum. When that nobleman was committed to the Tower, a handſome table was kept for Mr. Harriot, and ſome other mathematical friends with whom the earl paſſed the hours of his confinement in literary and ſcientific converſation. Sir Walter, being in the Tower at the ſame time, frequently joined their ſociety, and ſoftened the rigours of his impriſonment. Mr. Harriot died in 1621, in the ſixty-firſt year of his age. He was the ſubject of univerſal eſteem. While a young man he was ſtyled by Hakluyt, "Juvenis in diſciplinis mathematicis inſignis;" and by Camden, "Mathematicus inſignis;" he is ſpoken of in terms of no leſs reſpect by ſeveral other great and eminent men of his day. Mr. Harriot will always be remembered as the inventor of the preſent improved method of algebraical calculation. His improvements in algebra were adopted by Des Cartes, and for a conſiderable time impoſed on the French nation as his own, but the piracy was diſcovered and made known by Dr. Wallis, in his Hiſtory of Algebra. Mr. Harriot's work is entitled "Artis analyticæ praxis ad æquationes algebraicas nova expedita, et generali methodo reſolvendas, è poſthumis Thomæ Harriot." It appears from unqueſtionable evidence that Harriot was as able an aſtronomer, as he was celebrated in the analytic art. He was the firſt who obſerved the ſpots in the ſun, on which he made 197 obſervations. It is a matter of doubt whether he or Galileo firſt ſaw the ſatellites of Jupiter; he likewiſe made ſeveral obſervations upon the moon, the planet Mars, the ſolſtices, and comets. The knowledge of theſe facts was brought to light by Dr. Zach, an able aſtronomer, of Saxe Gotha, who had, in the year 1784, acceſs to the MSS. left by Harriot, and which are in the poſſeſſion of the earl of Egremont, a deſcendant of the earl of Northumberland, who was Harriot's patron.

HARRIS, Walter, in *Biography*, was born at Glouceſter about the year 1651. He took the degree of batchelor of phyſic at Oxford in October 1670; but having embraced the Roman Catholic religion in 1673, he quitted that univerſity, and received his doctor's degree from ſome univerſity in France. He returned to London in 1676, and commenced the practice of his profeſſion; and with a view to evade the operation of the order, that all Catholics ſhould quit the metropolis, in 1678, when he found his profeſſional reputation increaſing, he publicly renounced his errors, and profeſſed the Proteſtant faith. His practice was rapidly augmented, and on the acceſſion of William III. he was appointed phyſician in ordinary to that monarch. He died in 1725.

The principal work of Dr. Harris is ſaid to have been publiſhed on the ſuggeſtion of the celebrated Sydenham, and is entitled "De Morbis Acutis Infantum;" it was firſt publiſhed in 1689, and has paſſed through ſeveral editions. He left two other treatiſes, *viz.* one relative to the plague, including ſome account of inoculation as practiſed by the Turks and Chineſe, printed in 1721; and another containing ſome medical and ſurgical papers, which had been read at the college of phyſicians, 1725. Eloy. Dict. Hiſt.

Harris, John, the firſt compiler of a Dictionary of Arts and Sciences in this country, deſerves particular notice in the Cyclopædia, though no memorial of him has hitherto appeared in ſimilar publications. The inattention of his contemporaries has rendered it difficult to collect any authentic information concerning him. We have taken ſome pains in our reſearches for this purpoſe, and by favour of the late Mr. Iſaac Reed, who was no leſs communicative to his friends than induſtrious in acquiring every kind of literary intelligence, and by the aid of ſome other communications, we have been enabled to reſcue and to preſerve the ſubject of this article from oblivion. Mr. Harris was born about the year 1670, and received his education at St. John's college, in the univerſity of Cambridge, where he took the degree of batchelor of arts in 1687, and that of maſter in 1691. Having taken orders in the church, he obtained conſiderable preferments. He was firſt inſtituted into the rectory of Barming, which he reſigned for St. Mildred, Bread-ſtreet, London; he had alſo the perpetual curacy of Stroud near Rocheſter in Kent, and he was prebendary of Rocheſter cathedral. He was a fellow, ſecretary, and vice-preſident to the Royal Society. In 1698, he preached the courſe of Boyle's Lectures, which was publiſhed (ſee Collection of Boyle's Lectures, Feb. 1739. vol. i. p. 356—425); and in the next year he took the degre of doctor of divinity. Dr. Harris alſo publiſhed ſeveral ſingle ſermons, *viz.* a ſermon on the Faſt, 1701, with another on the Faſt, 1703, 4to.; a ſermon, intitled "the Modeſt Chriſtian's Duty as to indifferent things in the worſhip of God," 1705, 4to.; another on "The lawfulneſs and uſe of Public Faſting," 1706, 4to.; "The evil and miſchief of a fiery ſpirit," a ſermon publiſhed in 1710, 4to.; another on the rebellion in 1715, 8vo.; and a ſermon on the acceſſion, 1715, 4to. He alſo publiſhed a "Collection of Voyages and Travels, with a number of Engravings;" a "Treatiſe on the Theory of the Earth," in 1697; a "Treatiſe on Algebra," in 1702; a "Tranſlation of Pardie's Geometry into Engliſh," a 7th edition of which, in 12mo. was printed in 1734; "Aſtronomical Dialogues," the third edition of which appeared in 1795: but the work for which he was moſt eminently diſtinguiſhed, and which entitles him to honourable notice, was his "Lexicon Technicum," or "An Univerſal Dictionary of Arts and Sciences," in 2 volumes folio, publiſhed in 1708; from which originated all the other Dictionaries of Science and Cyclopædias that have ſince appeared. He was followed, at a conſiderable interval of time, in this department of literature, by Mr. Ephraim Chambers, whoſe Cyclopædia, with all the improvements it has received, has long maintained diſtinguiſhed reputation. We are concerned to be obliged to add, that though Dr. Harris was a man of unqueſtionable abilities and attainments, and of great literary application, he was chargeable with culpable imprudence in his conduct, and, notwithſtanding the preferments he enjoyed, he was generally in diſtreſs. He died Sept. 7, 1719, leaving unfiniſhed the "Hiſtory of Kent," which was publiſhed in folio ſoon after his death, and which, though it had engaged his attention, more or leſs, for eight years, is extremely inaccurate. Mr. Gough ſays (Britiſh Topography, vol. i. p. 445) "Dr. Harris died an abſolute pauper at Norton

Norton court, and was buried in Norton church, at the expence of John Godfrey, esq. who had been his very good friend and benefactor."

Harris, James, son of a gentleman of the same name, and lady Elizabeth Ashley, sister of the earl of Shaftesbury, the author of the Characteristics, was born at Salisbury in 1709, where he was educated under Mr. Hill, the master of the grammar school of that city. At the age of sixteen he was entered as a gentleman commoner at Wadham college, Oxford, from whence he removed to Lincon's Inn, meaning to study the law as a gentleman, but without looking to it as his profession. When he had attained his twenty-fourth year, by the death of his father, he came into possession of large property, retired to his native place, and devoted himself to the careful perusal of the best writers of antiquity. His first literary production was a volume containing three treatises on Music, Painting, and Happiness, which displayed a great extent of reading, and a penetrating judgment, clearly shewing that he was well fitted to reason upon, and illustrate speculative and abstract topics. In 1751 he published his most celebrated work, entitled "Hermes, or a Philosophical Enquiry concerning Universal Grammar." This treatise was received with great applause by the learned, and placed the author, in the general opinion, among the most profound and erudite dialecticians. Concerning this work the late bishop of Lowth observed, that "those who could enter deeply into the subject of universal grammar, will find it fully and accurately handled, with the greatest acuteness of investigation, perspicuity of explanation, and elegance of method, in a treatise entitled "Hermes," the most beautiful example of analysis that has been exhibited since the days of Aristotle." This high reputation it generally maintained till it was attacked by the acute, the sagacious and learned J. H. Tooke, who, for more than twenty years, seems to have borne away the palm, by his work entitled Επεα Πτεροεντα. There are those, however, who hold this work extremely cheap, and who still adhere to the theory of Mr. Harris as most learned, most rational, and most intelligent. (See our article Grammar.) Mr. Harris was no less a votary of the fine arts than of science. He was particularly sensible to the charms of music, and under his patronage the annual musical festivals at Salisbury greatly flourished. In 1761 he obtained a seat in parliament for the borough of Christchurch, and in the following year he was appointed to the office of one of the lords commissioners of the admiralty, which, in 1763, he was enabled to exchange for the place of a lord of the treasury. In 1765 he went out of office with the administration, which he had supported while in power, and, in 1774, he became secretary and comptroller to the queen, an honour which he highly valued, and which, with his seat in parliament, he retained till his death. Notwithstanding his official duties he spent much time in literary pursuits, and in 1775 he published his "Philosophical Arrangements," intended to illustrate the logic of Aristotle. His concluding work was given to the world in 1780, entitled "Philological Enquiries." In the same year he died, at the age of seventy-two. Mr. Harris possessed a profound knowledge of the Greek language, which he applied to the study and explanation of the ancient philosophy; he was admired and revered as a man of profound learning, he was beloved by his family and friends, and, as we have seen, was entrusted with the discharge of several important offices in the state. He left one son, the present earl of Malmesbury, who published a complete edition of his father's works, with an account of his life, in two vols. 4to., to which the reader is referred.

This excellent scholar, and most worthy and respectable character, in the early part of his life, cultivated music with as much assiduity as the learned languages and Categories of Aristotle. In his ingenious "Essay on Music," he illustrates his precepts and reflexions almost exclusively from Handel; but keeping pace with the times in the refinement of melody, without injuring harmony, Jomelli and Sacchini became his favourite composers: the first for rich harmony and grand and new effects; the second for grace, pathos, and delicacy.

The city of Salisbury, where Mr. Harris had established musical performances with superior taste and intelligence, will long deplore his loss; not only as the patron and guide of that art, and for his profound learning; but for his candour, liberality, and universal benevolence.

Harris senior, and Renatus Harris, his son, two eminent organ-builders, called hither from France, soon after the restoration, to supply our churches with instruments, which, during the grand rebellion and the interregnum, had been injured, banished, or destroyed, were excellent workmen, only inferior to father Smith, to whom Renatus, after the death of his father, in 1672, became a formidable rival.

The contention between these eminent artists, at the time of erecting the admirable organ which still stands in the Temple-church, was carried on with such spirit, not to say violence, as perhaps never happened before, or since, on a similar occasion.

About the latter end of the reign of Charles II., the master of the Temple and the benchers being determined to have as complete an organ erected in their church as possible, received proposals from both these eminent artists, backed by the recommendation of such an equal number of powerful friends and celebrated organists, that they were unable to determine among themselves which to employ. They therefore told the candidates, if each of them would erect an organ in different parts of the church, they would retain that which, in the greatest number of excellencies, should be allowed to deserve the preference. Smith and Harris agreeing to this proposal, in about eight or nine months, each had, with the utmost exertion of his abilities, an instrument ready for trial. Dr. Tudway living at the time, the intimate acquaintance of both, says that Dr. Blow and Purcell, then in their prime, performed on father Smith's organ, on appointed days, and displayed its excellence; and, till the other was heard, every one believed that this must be chosen.

Harris employed M. Lullie, organist to queen Catharine, a very eminent master, to touch his organ, which brought it into favour; and thus they continued vying with each other for near a twelve-month.

At length, Harris challenged father Smith to make additional reed-stops in a given time; these were the vox-humana, *cromorne*, the double courtel, or double bassoon, and some others.

The stops which were newly invented, or at least new to English ears, gave great delight to the crowds who attended the trials; and the imitations were so exact and pleasing on both sides, that it was difficult to determine who had best succeeded. At length, the decision was left to lord chief justice Jefferies, afterwards king James II.'s pliant chancellor, who was of that society, and he terminated the controversy in favour of father Smith; so that Harris's organ was taken away without loss of reputation, having so long pleased and puzzled better judges than Jefferies.

The Hon. Roger North, who was in London at the time of the contention at the Temple-church, says, in his Memoirs of Music, that the competition between father Smith

and Harris, the two beſt artiſts in Europe, was carried on with ſuch violence by the friends of both ſides, that they "were juſt not ruined." Indeed old Roſeingrave aſſured us, that the partizans for each candidate, in the fury of their zeal, proceeded to the moſt miſchievous and unwarrantable acts of hoſtilities; and that in the night preceding the laſt trial of the reed-ſtops, the friends of Harris cut the bellows of Smith's organ in ſuch a manner, that when the time came for playing upon it, no wind could be conveyed into the wind-cheſt.

Harris's organ, after its rejection at the Temple, was part of it erected at St. Andrew's, Holborn, and part in the cathedral of Chriſt-church, Dublin.

HARRIS, WILLIAM, was born at Saliſbury about the year 1720. He was educated for the profeſſion of a diſſenting miniſter at Mr. Grove's academy, Taunton, and firſt ſettled with a congregation at St. Loo, in Cornwall. From this place he removed to Wells, where he was ordained, and reſided ſome years. He next went to Honiton, the native place of the lady whom he married, and at Luppit, in its neighbourhood, he continued to preach till his death. He became more diſtinguiſhed as a writer than a preacher, and was firſt known in that line by an "Account of the Life of Hugh Peters," which he publiſhed in 1751, after the manner of Bayle. The facts contained in this piece are chiefly taken from Peters' dying advice to his daughter. This was followed by hiſtorical and critical accounts of the lives of James I., Charles I., Oliver Cromwell, and Charles II. printed at different times, between the years 1754 and 1766. They conſiſt of five volumes 8vo. and are written after the manner of Bayle, in order that he might have an opportunity of entering into diſquiſitions, and to indulge in reflections in the notes, which in the text would have interrupted the connection, and been inconſiſtent with the even tenor of the narrative. The characteriſtics of Mr. Harris, as a writer, were diligence in collecting materials, exact fidelity in quoting authorities, and impartiality in ſtating facts drawn from authentic ſources, original writers, and ſtate papers. He was an ardent friend to liberty; and every inſtance of perſecution, tyranny, and oppreſſion raiſed his honeſt indignation: his hiſtories were written, not for the ſake of thoſe who govern, to ſhew them how they may act moſt at their eaſe, but for the uſe of the people to point out to them that they have, inherent in themſelves, claims of rights, liberties, privileges, and equal government. Mr. Harris was patronized in his various labours by Mr. Thomas Hollis, the enlightened and zealous friend to freedom, who, without regard to expence, liberally procured for him the materials requiſite for his compoſitions. He died at Honiton in the year 1770. The degree of D.D. had been conferred upon him by the univerſity of Glaſgow in the year 1765. He was author of ſome anonymous pieces, particularly of an anſwer to "An Eſſay on Eſtabliſhments in Religion," by Mr. Rotheram, who had written, it was ſuppoſed, under the direction of archbiſhop Secker. All Mr. Harris's works have been well received, and thoſe who differ from him in principles, highly eſteem him on account of his induſtry and faithfulneſs as an hiſtorian. As a preacher, his diſcourſes were plain and practical; as a man and Chriſtian, he was diſtinguiſhed by ever expreſſing a juſt indignation of whatever was baſe and diſhonourable, by an inflexible integrity, and by a ſeries of liberal and benevolent actions; his heart was friendly, and his manners marked by frankneſs and ſimplicity. Monthly Magazine, vol. x.

HARRIS, in *Geography*, one of the Hebrides, or weſtern iſlands of Scotland, united to *Lewis* by a narrow iſthmus, dry at low water, and partially covered by the tide, and forming with the iſlands to the ſouthward a chain called the "Long iſland," upwards of 200 miles in length, and from three to 20 in breadth. On the E. ſide theſe iſlands, in general, are rough and mountainous, and on the W. they are, in many parts, level, ſandy, and tolerably fertile. Harris, which is the ſouthern diviſion of Lewis, lies in N. lat. 57° 40', being 15 miles in length, and from 6 to 12 in breadth, and contains 2600 inhabitants, ſcattered along the coaſts, including thoſe of various contiguous iſlets. The eaſt ſide of this iſland is rocky and indented with bays and inlets; but on the W. are ſome tolerable farms. The face of the country is rugged and mountainous, affording paſtures to horſes, cattle, and ſheep, and abounding in freſh-water lakes and rivers, ſtored with fiſh. It contains ſeveral remarkable caves, and particularly one called Ulweal, capable of accommodating 50 perſons The channel on the ſouth coaſt is navigable for veſſels of burden under the direction of a ſkilful pilot. The northern diſtrict is an aſſemblage of conical hills, without inhabitants. Kelp is the ſtaple article for exportation from this and the neighbouring iſlands.

HARRISBURG, originally *Louiſburg*, a poſt town of America, and the capital of Dauphine county, Pennſylvania, ſituated on the N.E. banks of Suſquehanna river. It is regularly laid, and contains about 400 houſes, a ſtone-gaol, a German church, and a court-houſe. Its inhabitants amount to 1472. Immenſe quantities of lumber are annually brought hither from the country above, and it has manufactures of leather, hats, and nails; 107 miles W. of Philadelphia. N. lat. 40° 16'.

HARRISON, JOHN, in *Biography*, the celebrated inventor and maker of the watch called the "Time-keeper," for aſcertaining the longitude at ſea, and alſo of the grid-iron *Pendulum* (which ſee); was born at Foulby, near Pontefract, in Yorkſhire, in the year 1693. His father was a carpenter, and being unable to ſupply his ſon with much education, he employed him, as ſoon as he was able, in his own buſineſs, and occaſionally, as is uſual with country mechanics, in land-ſurveying, and repairing clocks and watches. An inſtance given of his attachment to machinery is, that when he was only ſix years old, his mind was diverted from the tedium and pain occaſioned by the ſmall-pox, by contemplating the movements of a watch which was placed open upon his pillow. He removed with his father in the year 1700 to Barrow in Lincolnſhire, where he was indulged by the clergyman of the place with the loan of a manuſcript copy of profeſſor Saunderſon's Lectures, which he carefully and neatly tranſcribed. In 1725 he had ſo far ſurmounted the difficulties of his ſituation, that he had conſtructed two clocks, chiefly in wood, but he had applied to them the eſcapement and compound pendulum of his own invention. Theſe pieces of workmanſhip ſurpaſſed every thing of the kind then made, ſcarcely wandering from the truth one ſecond in a month. Encouraged by this ſucceſs he came to London with his clocks, which he ſhewed to Dr. Halley, and Mr. Graham, who encouraged him to proceed in his deſign. With this advice he readily complied, and having returned home, completed his machine, which anſwered his expectations in a long trial, during much bad weather, and ſubject to the motions of a veſſel on the river Humber. In the year 1736 he viſited the metropolis again, with a machine which was ſhewn to the board of Longitude, who ſent him with it to Liſbon to make a trial of its properties. In this ſhort voyage he corrected the dead reckoning nearly a degree and half; a ſucceſs which proved the means of his receiving both public and private encouragement. From this time he went on improving his invention, and at length received the promiſed reward of 20,000*l*. He died in the year

year 1776, having nearly completed his eighty-third year. Mr. Harriſon's cloſe and unremitted attention to the purſuit of one object diſqualified him for entering deeply into other kinds of knowledge. On mechanics, and topics connected with this ſcience, he could converſe with preciſion and great clearneſs, but he found it very difficult to deliver his meaning in writing, which was evident in his "Deſcription concerning ſuch mechaniſm, as will afford a nice or true Menſuration of Time." This work contains alſo an account of his new muſical ſcale, or mechanical diviſion of the octave, according to the proportion which the radius and diameter have reſpectively to the circumference. Mr. Graham, whoſe name has been mentioned above, was not only the beſt watch and clock maker of his time, but a complete mechanic and aſtronomer. He made and divided with his own hand the great mural arc in the Obſervatory of Greenwich, and from this very inſtrument the beſt foreign arcs have been copied by Engliſh artiſts. He conſtructed the ſector by which Dr. Bradley made his diſcoveries of the motions in the fixed ſtars; and he ſupplied the French academicians with inſtruments when they were ſent into the north to aſcertain the figure of the earth. He was a fellow of the Royal Society, and communicated to that learned body many valuable papers.

HARRISON, in *Geography*, a townſhip of America, in Weſt Cheſter county, New York, containing 856 inhabitants.—Alſo, a county in the weſtern part of Virginia, bounded N. by Ohio county, N. E. by Monongalia, S. by Greenbriar, and S. W. by Kenhawa; about 120 miles long, and 80 broad, containing 4603 free inhabitants, and 245 ſlaves. Its chief town is Clarkſburg.—Alſo, a county in the N. E. part of the ſtate of Kentucky, N. of Bourbon; well watered, and containing 4263 inhabitants. Its chief town is Cynthiana.—Alſo, a cape on the E. coaſt of Newfoundland. N. lat. 54° 9'. W. long. 57°.

HARRISON's *Temperament* of the muſical ſcale. In the preface to Dr. Smith's "Harmonics" we are informed, that the late Mr. Harriſon, who conſtructed the famous longitude watches, applied a temperament in adjuſting the frets on the neck of his baſe-viol, wherein the interval of the octave bore the ſame ratio to its major third, as the circumference does to the diameter of a circle; of courſe ·9041791.66 is the logarithm of this third, $=194.77767\,\Sigma + 4f + 17\,m$, or the temperament of it is flat, $2.22233\,\Sigma$; whence, by Mr. Farey's Corollaries, in the Philoſophical Magazine, vol. 36. p. 375, we have, $-3.30754\,\Sigma$ the flat temperament of the fifths, and $+ 1.08521\,\Sigma$ the ſharp temperament of the major ſixths; the wolves, which are very great, may be obtained from the ſame corollaries, if wanted.

HARRISTOWN, in *Geography*, in the county of Kildare, and province of Leinſter, Ireland, a *ſingle houſe*, which, previous to the union, returned two members to the Iriſh houſe of commons, under the direction of one of the Latouche family. It is $2\frac{1}{2}$ miles from Kilcullen bridge.

HARROD's CREEK, a river of Kentucky, which runs into the Ohio. N. lat. 38° 11'. W long. 86° 2'.

HARRODSBURG, or HARRODSTOWN, a poſt-town of America, in Mercer county, Kentucky, at the head of Salt river, containing about 20 houſes; 825 miles S. W. of Philadelphia.

HARROW, in *Fortification*, is a gate made of timber, whoſe dimenſions are commonly ſix by four inches, and ſix inches diſtant from each other, well faſtened to three or four croſs bars, and ſecured with iron.

HARROW, called *Harrow-on-the-Hill*, in *Geography*, is a pariſh in the hundred of Goare, and county of Middleſex, England. The village ſtands on the higheſt hill in the county, whence originated its appellation. This hill appears to riſe out of a rich vale, and aſſumes an inſulated character; whereby the proſpects from its apex are extenſive and varied, whilſt the town on the top is ſeen from very remote diſtances to the W., S. W., and N. W. Harrow had formerly a weekly market, which is now diſuſed. It is ten miles from Tyburn-Turnpike, London, and contains 378 houſes, and 2485 inhabitants. The pariſh contains about 13,600 acres of land, of which 1600 are waſte. It comprehends the hamlets of Pinner, Roxey, Wembley, Weald, Apperton, Reaton, and Preſton. Previous to the Norman conqueſt this manor belonged to the ſee of Canterbury; and the archbiſhops had a manor-houſe here. They had another manſion in the manor of Heggeton, in the Pinner diviſion of this pariſh. The church is partly of ancient architecture, and appears to have been firſt built by Lanfranc, in the time of king William I. Parts of this building are ſuppoſed to remain, in the columns between the nave and aiſles, and the lower part of the tower. In the church are ſeveral ſepulchral monuments; one to ſir John Flambard; another to John Lyon, founder of Harrow-ſchool, who died 1592; and a third to Dr. Sumner, with a Latin epitaph written by Dr. Parr. The free-ſchool of this place now ranks among the moſt eminent public ſeminaries in the kingdom, and gives Harrow its chief celebrity. The founder drew up the ſtatutes for its government with much attention and preciſion; ſpecifying the routine of inſtruction to be purſued; mode of correction; hours of attending ſchool, and objects of diverſion, for play-hours. Theſe are "driving a top, toſſing a hand-ball, and running and ſhooting." The latter ſport has been diſcontinued above forty years. A competent number of poor ſcholars were to be educated free of expence, and the maſter allowed to take other children for his own emolument. No girls were to be admitted. The ſum of 20*l.* was allotted for two exhibitions to Caius college, Cambridge, and two more to Oxford. This ſum is now raiſed to 20*l.* for each boy. Governors of title and high reſpectability are appointed to controul and regulate the government of the eſtabliſhment; and men of conſiderable claſſical attainments have been ſelected as maſters. The number of ſcholars is generally about one hundred and fifty. Mr. Lyſons ſtates, that "the preſent rent of Mr. Lyon's eſtates amounts to 669*l.* which is expended by the governors in paying the maſters' ſalaries, and the exhibitions, educating poor children, relieving decayed houſekeepers, repairing roads, &c." In this pariſh the marquis of Abercorn has a handſome ſeat, which contains a valuable collection of pictures, by the old maſters, ſome antique buſts, &c. Lyſons's Environs of London, 4to. vol. ii. 1795.

HARROW, in *Huſbandry*, the name of a tool employed on tillage land, for the purpoſe of breaking down and reducing the lumpineſs of it, as well as the covering in the ſeed when ſown upon it. It conſiſts of a kind of wooden frame, commonly conſtructed in the form of a ſquare, and ſet with numerous teeth, or tines made of iron.

There are ſeveral different ſorts or deſcriptions of harrows made uſe of in the buſineſs of tillage huſbandry; but the moſt uſual are thoſe of the ſingle and double brake harrow, the triangular harrow, the iron harrow, &c.

It is neceſſary, in the cultivation of land, that the tools of this nature ſhould vary conſtantly in their ſizes and weight, as well as in the lengths and ſtrengths of the teeth or tines, in proportion to the nature of the ſoils on which they are to be employed, and the different purpoſes for which they are intended.

Harrows, though tools of great utility in the work of arable cultivation, have hitherto undergone but very little improvement in their conſtruction; the principal points in which they have been rendered more beneficially applicable and convenient for uſe, appear to be in the form of the frames; the poſition and manner of fixing in the tines or teeth into them; the directions of the bulls or ſolid parts; and in the method of attaching the draught to the tools.

It has been hinted by a late writer, on the authority of much experience, that there is no one harrow, whatever the nature of its conſtruction may be, that can be applicable to every deſcription of ſoil, or which can operate with equal effect and advantage on ſuch lands as are rough and ſmooth, looſe and ſolid, &c. It is neceſſary that they ſhould conſtantly be fitted to the particular nature of the ſoil, and the peculiar uſes for which they are employed. In the lighter ſorts of ground, it is obvious, that ſmaller and lighter ſorts of harrows, with ſhorter teeth, may fully anſwer the purpoſes of the cultivator, than in ſuch as are ſtrong, heavy, and tenacious, or which have been lately broken up from the ſtate of old ſward, and that of common moor heath, and other ſorts of waſte, where they ſhould have much greater weight and length of tines.

And it is frequently the practice, in caſes where the ſoil is rough and ſtubborn, as in ſome inſtances of fallowing ſtiff clayey lands, to unite two common harrows together, in order more completely to reduce and break down the lumpineſs of ſuch grounds. And in the view of effecting theſe purpoſes, eſpecially where the ſoil is ſtiff, adheſive, and much matted with weeds, it has been found advantageous not to have the harrows too thickly ſet with tines; as by this means they are not ſo liable to become choaked up, and prevented from working in a proper manner, nor in reducing the earthy materials of ſuch grounds.

In the buſineſs of harrowing much time is frequently loſt in turning at the ends of the ridges, eſpecially where double harrows are in uſe, by their hitching or riding upon each other, or turning over, in putting them right again; it has been attempted to remove ſuch inconveniencies by having the harrows conſtructed with running bulls, which are ſaid to anſwer the purpoſe very perfectly. But it has been lately ſuggeſted, that inconveniences of this nature may be obviated in a much more ready manner, and with far leſs expence, by the mere faſtening of the different harrows together by means of ſuitable hooks and eyes, or what in ſome places are denominated coupling-irons; as in this way the different harrows are ſuffered to riſe and fall at the ſame time, and thereby kept from riding over each other.

In the forming of harrows, ſome differences in the poſitions of the teeth have likewiſe been attempted, in order that they may not move in the ſame lines of direction. This has been tried in ſeveral different modes, but the moſt eaſy, ſimple, and expeditious contrivance ſeems to be that of forming the harrows in ſuch a way, as that they may be ſome inches narrower in the fore than the hind parts, and be capable, at the ſame time, of being ſet to different widths, by which, the diſtances between the tines may be regulated by ſimply augmenting or diminiſhing the ſpaces between the fore and the hind parts of the tools.

In harrows of the common kinds, this object is uſually accompliſhed, in ſome degree, by their being attached to the moving power in ſuch a way as that they may be dragged over the ſurface of the ground in a ſort of diagonal line of direction.

It may be noticed, that in the conſtruction of all the kinds of the larger deſcriptions of harrows, it is a circumſtance that ought to be conſtantly attended to, that the tines, or teeth, be put in, in ſuch a manner, as to have ſome degree of inclination forward; as by their being placed in this way, the tools are found not only to be capable of performing a great deal more work in the ſame time, but of keeping more cloſely to the ground, as well as of cutting and tearing up, in a more effectual manner, all ſuch weeds, roots, or other ſimilar matters, as are met with in the execution of the buſineſs.

It has been recommended by ſome to be an excellent method, eſpecially with all the larger ſorts of harrows, to have the tines put into the bulls by means of nuts and ſcrews, ſo that they can be readily removed when neceſſary, and at the ſame time be kept ſecure while they are at work. But another more ſimple mode of effecting the ſame intention, is that of having the heads of the tines formed in a ſquare manner, with eyes towards the tops of them, the ſquare parts being put upwards through the bulls, and ſecured above by iron wedges, ſo as to keep them perfectly faſt, and prevent their ſhaking out, and being loſt in working.

In addition to theſe different methods of forming harrows, they have likewiſe been occaſionally conſtructed with the tines of unequal lengths, the firſt row, in ſuch caſes, being a quarter, or half an inch ſhorter than that of the ſecond, and ſo on in regard to the reſt. It is ſuppoſed that harrows, formed in this way, are capable of performing more work in a given time, as well as of being much more readily cleared from weeds and other collected matters with which they are apt to be choaked up, than thoſe of other kinds.

This deſcription of harrow has been ſtated to be much in uſe in ſome parts of the county of Devon, and alſo to have been lately introduced into ſome of the midland counties with conſiderable benefit. They have been made in ſeveral different modes, as with greater and leſs numbers of bars, from three to five, ſix, or more, the tines varying in the ſame proportions.

It has, however, been found by the moſt attentive cultivators of land, that, in general, ſingle horſe-harrows are more uſeful than thoſe that require two or more horſes. In their attachment to the power by which they are drawn, the moſt uſual method is that of a ſtrong ſort of ſtaple, which is fixed to one of the corners of the harrow by means of a bolt; but a more improved and convenient mode is that of connecting the muzzle with a perpendicular pin to one of the angles of them, as in this way they are uſed with greater facility, with a view of avoiding the difficulties of turning at the ends of the ridges, and for leſſening the weight on the backs of the horſes, which have, in ſome caſes, been made an addition to the harrow. But, from the nature of the work, it would ſeem that but little advantage can be gained in this way.

Various other improvements have been made on harrows by different individuals; and the harrow and roller have been lately combined by Mr. B. Young, a farmer in the Iſle of Wight, by which it is aſſerted there is a ſaving of a man and horſe, as well as other advantages.

Common Single Harrow.—This is a tool ſo perfectly known to the farmer, that very little deſcription of it is required. It generally conſiſts of four bulls, or bars, about four inches ſquare, into each of which are inſerted four or five tines or teeth. From the nature of its conſtruction, it is lighter than moſt of the other ſorts of harrows, being capable of being wrought with facility by a ſingle horſe. It is ſhewn in *Plate Harrow, fig.* 1. And an improved harrow of the ſame kind may be ſeen at *fig.* 2. in the ſame plate.

Common Double Harrow.—This is a ſort of harrow which is uſually formed merely by uniting two ordinary ones with hooks and eyes. They have commonly each four bulls, and ſix tines in each bull. This ſort of harrow is in very general uſe, in ſome diſtricts, for the purpoſe of brake-harrowing, or breaking down the rough tillage ſoils, while at the ſame time it is capable of ſupplying the place of the common harrow; but it is not by any means ſo eaſily wrought, as it requires much more power. It is not neceſſary to give any repreſentation of this kind of harrow, from its being ſo well known.

Common Brake Harrow.—This is a large maſſy kind of harrow, of conſiderable weight, having commonly four bulls, with five or ſix long tines fixed into each. It is an extremely powerful tool in reducing ſtiff, rough, heavy land into a powdery ſtate, in bringing it into cultivation; as well as for looſening couch-graſs, and other root-weeds, in the courſe of a naked or ſummer-fallow. It is, in ſome caſes, alſo employed after the ſeed is ſown, previouſly to the uſe of the lighter ſorts of harrows; and is commonly drawn by three or four horſes, though in ſome places by two horſes, and the ſame number of oxen.

Harrows of this deſcription have lately undergone much alteration and improvement by different perſons, ſo as to render them leſs difficult in their management, and give them more facility in the draught. And in ſome caſes it has been found uſeful to have them made of different ſizes, even ſo ſmall as to be capable of being drawn by one horſe. Theſe are made exactly in the ſame manner as thoſe of the larger kind, and may be formed by any common workman. The only difference in them is that the tines ſhould only be about ſeven inches in length.

The large improved harrow of this nature has uſually three or four bulls, which contain about thirty-four tines that have the length of about eleven inches, and which are a little racked or bent forward, by which means they do not ſo readily riſe out of the ground on meeting with obſtructions, and have the power of reducing the ſoil much more perfectly.

The two narrow parts are connected together by the uſe of iron hooks and eyes, ſo as to be at the ſame diſtance that the different bulls are from each other, by which they work much better, and with conſiderably leſs power of draught than when they are placed nearer to each other. The harrows would likewiſe have greater width behind than before, as by this contrivance they more readily relinquiſh the mouldy particles, and gather the roots of couch and other weeds far more effectually. A well conſtructed harrow of this deſcription is ſhewn at *fig.* 3, in which *a* is the moveable hook and bridle; *b*, an iron placed acroſs two bulls with holes perforated in it to receive the bridle-bolt, where neceſſary to remove it; *c*, *d*, the crooks and eyes for uniting the two harrows, with the bolts through the bulls, and nuts, and ſcrews; *e*, *f*, are the two fore-bolts, or wedges, in each harrow; *g*, *h*, the two hind ones; *i*, *k*, *l*, *m*, *n*, *o*, ſhew the three bulls of the foremoſt and hindmoſt harrows, which are capped with iron at the upper ends, to keep the bulls together, and make them ſlide more readily by any obſtructing matters; *p*, *p*, are the handles by which the harrow is lifted up or weighed upon; *q* ſhews the form of the tines, with the nuts and ſcrews for faſtening them in with.

There are other modes of forming and connecting harrows, beſides thoſe that have been noticed above; one of which is diſplayed at *fig.* 4, in which *a* is the piece of wood or iron by which the two harrows are united to each other with nuts and ſcrews, as at *t*, *t*; the places and method of attaching the draught to them is ſeen at *b b*; and *c c* diſplays the mode of fixing the horſes or other cattle in working them. This kind of harrow is in much employ in many places, eſpecially in the more northern parts of the kingdom, being often drawn with one horſe.

There is a method employed to prevent harrows from getting over each other, where two or more are made uſe of together, that is generally practiſed in the northern diſtricts, which is that of placing a bar of ſome tough wood, uſually called a *lay over*, acroſs them; or a piece of crooked timber fixed to the outſide bulls, which approach each other, may anſwer the ſame purpoſe.

Wheel-Harrow.—This is a ſort of harrow which was invented by Mr. Knight, a farmer at Great Barfield, in Eſſex, and conſiſts of a frame of wood ſomewhat in the form of the common harrow, to the fore-part of which is attached a pair of low wheels, that are ſo managed as to raiſe or lower the harrow part at pleaſure.

Iron Harrow.—This is conſtructed wholly of that metal, and was invented by Mr. A. Young, in conſequence of his finding, from actual experience, that ſuch harrows as are formed of wood are apt to ſoon decay and fall in pieces; and in many caſes to be much too light to anſwer the intended purpoſe. The tines in this ſort of harrow are made ſo as to ſcrew through the double frame, which is ſeparated by a kind of iron waſhers, in order to afford greater ſteadineſs. It has likewiſe handles fixed to it for the purpoſe of raiſing it more conveniently, as well as to afford due preſſure where neceſſary. When formed in this way, the tool has been found to anſwer in the moſt perfect manner, while at the ſame time it is much more durable than the common ſorts of harrows. It is capable of being varied in its conſtructions, ſo as to ſuit the different intentions of the farmer. When well made, and rendered complete, it uſually coſts about ſix pounds ſix ſhillings. It may be ſeen at *fig.* 5.

Graſs Harrow.—In many parts of the kingdom it is the cuſtom to make uſe of a ſmall light kind of harrow, with ſhort light tines, ſet very cloſe upon the graſs lands, eſpecially where they are much ſubject to be over-run with moſs, in order to break and deſtroy its matted roots. It is alſo beneficial in covering in graſs-ſeeds, as well as other ſmall kinds of ſeeds, though much too little had recourſe to in ſuch caſes; as it is capable of not only rendering the bed of mould much more fine, but alſo of introducing the ſeed to the moſt proper depth, and covering it in the moſt complete manner. Where graſs-ſeeds are to be ſown over thin, patchy, ſward lands, this ſort of harrow may likewiſe be previouſly employed with great advantage. A harrow of this nature may be ſeen at *fig.* 6.

It has been ſtated, in the ſurvey of the county of Mid-Lothian, in the view of explaining the advantages that may reſult from the difference of poſition in the teeth or tines, that, in the harrow which is repreſented at *fig.* 2. and which is conſtantly drawn in the direction of the line *a a*, the twenty tines only form eleven different ruts or tracks, as a number of them follow each other in the ſame lines, and even ſome of theſe are not in the leaſt effective, as the two on the extreme corners *a*, *a*, *a*, *a*, are ſo unconnected with the reſt, as to be of no utility in the work, conſequently ſeven ruts, as ſhewn by the dotted lines in the figure, are only found to be properly executed. From this circumſtance, it of courſe happens that one harrow, when drawn ſingly, only covers three feet of ground; two, not more than about ſix feet; and three, which, though they do more in proportion, only cover ten feet; while the improved harrow that is ſeen at *fig.* 2. though it has only ſixteen tines, yet as each tine forms a ſeparate track in the

the direction ſhewn by the dotted lines, one harrow, when drawn ſingly, will cover four feet and a half; two harrows about eight feet, and three will cover twelve feet; while at the ſame time the ruts or tracks are only three inches eight tenths aſunder; though in the common harrow they are ſix inches apart.

But, if the common harrow were drawn in the direction *b b*, the twenty tines mould conſtitute ſixteen ruts, though the one on each ſide, at the two oppoſite corners diagonally, would be more effective: and after all, this direction of the draught is not practicable with any but one harrow at a time, as where two or more are united, the dragging of the moſt diſtant one would interfere with that which is immediately before it. But in the improved harrow, the dimenſion is a ſquare of four feet, without the projection of the bulls at the ends. In the plate, the imaginary lines *a*, *a*, point out the direction of the draught; and *b b* is another line of the ſame kind, ſerving merely to ſhew the regular diſtance of the ruts, the figures at each tine exhibiting the diſtance in inches, at which they ſhould be inſerted from the extremities of the bulls.

HARROW, *Buſh*, the name of a ſort of harrow which is formed by the interweaving of ſome kind of bruſh-wood into a ſort of frame conſtructed for the purpoſe, and raiſed in the fore-part by two ſmall wooden wheels. It is occaſionally employed in putting graſs or other ſmall ſeeds, as well as for harrowing in dung, and earthy compoſts into graſs lands. See BUSH-*Harrow*.

HARROW, *Reſt*, in *Botany*. See ONONIS.

HARROW, *Triangular*, in *Rural Economy*, the name of a harrow which is conſtructed in the triangular ſhape, and which is often found beneficial in cleaning between the rows of bean, hop, and other ſimilar crops. But a ſuperior tool for this purpoſe will be noticed in ſpeaking of horſe-hoes. See HOE, and HORSE-*hoe*.

HARROWGATE, in *Geography*, a townſhip in the pariſh of Knareſborough, Claro-wapentake, and Weſt Riding of the county of York, England, has acquired conſiderable publicity from its medicinal ſprings, and is much frequented, in the ſummer months, by perſons to drink the waters. One of the ſprings diſcharges the moſt ſtrongly impregnated ſulphurated water of any in the kingdom. This is moſtly uſed for bathing by perſons in dropſical-ſcorbutic, and cutaneous diſorders, and is ſituated at Lower Harrowgate. About half a mile from the town is a chalybeate ſpring, called the Tewit-well. The Old Spa, diſcovered in 1571, is ſtrongly impregnated with iron, and its waters are recommended as a powerful tonic. The fame of theſe waters attracts much company to the place, and ſeveral large inns and lodging-houſes have been built for their accommodation. Among theſe are ſix inns or taverns, on a heath about one mile from the town. Here are an aſſembly room, a theatre, a promenade room, a library, billiard-room, &c.

Harrowgate lies two miles N.W. of Knareſborough, and 212 N. of London. Dr. Garnett publiſhed a pamphlet on the Qualities and Uſes of the Harrowgate Waters.

HARROWING, in *Agriculture*, the operation or action of the harrow in the performance of its work; which is a ſort of proceſs that is had recourſe to in ſeveral different intentions, ſuch as thoſe of reducing and breaking down the lumpineſs of the earthy matters, ſmoothing the ſurface of the ground after it has been ploughed, and the covering in the various kinds of ſeeds, whether of the grain or other deſcriptions. And it is not a leſs effectual means in the clearing of land from different ſorts of root and other weeds. In the execution of the firſt and laſt of theſe purpoſes, the more large and heavy kinds of harrows are in general employed, but for the mere purpoſe of covering in the ſeed, the lighter ſorts are commonly preferable.

It has been ſtated, that in ſome diſtricts it is the cuſtom, where ſingle harrows are made uſe of, for a man to drive three horſes and as many harrows, which, it is aſſerted, will do nearly, if not quite as much work, and in as effectual a manner, as four horſes in pairs, and two men are capable of executing, which is a circumſtance that ſhould not be diſregarded by the attentive farmer.

It is ſcarcely neceſſary to bring to the notice of the cultivator the great advantage that is derived from having the ſurface of tillage-land made ſmooth and even, and the mouldy parts properly broken down and reduced to a powdery condition after the ſeeds have been ſown. By theſe means the ſeeds not only derive a greater proportion of nouriſhment from the ſoil, but the particles of moiſture are more effectually retained in the ground, and, conſequently, the proceſs of vegetation proceeds in a more regular and exact manner.

It muſt be evident that ſtrong heavy lands will require much more harrowing in proportion, in order to reduce them into a proper ſtate of pulverization, than ſuch as are of a lighter nature, but at the ſame time, as all ſorts of land are rendered more firm and ſolid by the operation, the leſs ſtrong ſoils are harrowed the better, provided the intentions of the cultivators are accompliſhed. On the contrary, light ſpongy ſoils, eſpecially where there is any portion of moſſy or peaty matter, as they are rendered more compact and more retentive of moiſture by the proceſs, can ſcarcely have too much of the harrow. And it may be noticed, that light gravelly or ſandy ſoils ſhould be ſtirred as little as poſſible by the proceſs of harrowing, during the prevalence of hot or dry weather, in order that there may be as ſmall an eſcape as poſſible of their neceſſary moiſture. Nor ſhould thoſe of the more ſtiff, tenacious, and moiſt kinds be ever much touched by the harrow during wet ſeaſons.

In regard to the mode of performing the work of harrowing, it varies a little according to circumſtances. In covering in the ſeed after it has been ſown, the common and moſt uſual method of harrowing is in the firſt inſtance, along the ridges, then occaſionally acroſs them, and ultimately along them again. But where the ridges are level, or nearly approach to it, they are capable of being harrowed in either direction, at the pleaſure and convenience of the perſon who has the cultivation of the land, and it is of no material conſequence in what direction the harrow firſt paſſes them, when they are well ploughed, and the land is in a proper ſtate of tilth. In caſes, however, where the ridges are raiſed in the middle, and the ground but indifferently ploughed, it would be extremely improper to begin the work of harrowing by paſſing in a croſs direction of them, as by that means a conſiderable proportion of the ſeeds would be forced into the bottoms of the furrows and other crevices, and in that way be prevented from vegetating in a proper manner.

But in inſtances of harrowing where the principal intention is that of tearing up and deſtroying the roots of weeds and other noxious plants, which have been previouſly looſened by the uſe of the plough, conſiderably more effect will be produced by the harrows paſſing in a contrary direction to that in which the plough has gone, as the tines or teeth will be capable of drawing out a much larger quantity of ſuch roots than if they followed the courſe which the plough had taken.

In the work of harrowing for the mere deſtruction of ſeed-weeds, the mould of the land can ſcarcely be made too ſmooth on the ſurface, or too fine in its earthy particles: as by ſuch means, thoſe ſeeds which are near the ſurface will

vegetate

vegetate with more freedom, and in a more vigorous manner, and be thereby more readily extirpated from the ſoil by the ſubſequent harrowings that may be given to the land. In the work of making naked fallows, this ſhould be particularly attended to by the farmer.

In the buſineſs of harrowing there is ſtill another circumſtance which ſhould not by any means be overlooked. It frequently happens that after a field has undergone a proper naked or ſummer fallowing, been perfectly manured, and prepared in the beſt poſſible manner for the ſowing of wheat, that this cannot be performed in conſequence of the heavy falls of rain. For though it may ſeem as if there were no water upon the land, yet it is found ſo poachy and wet on trial, that no horſes can be put upon it for the purpoſe of harrowing in the ſeed, and the crop is merely thereby prevented from being put into the ground in due ſeaſon. This inconvenience has been attempted to be removed in ſome parts of Scotland, by the means which are deſcribed below, and which, where the ridges are pretty ſtraight, and not over broad, or too much raiſed in the crown, has been found to ſucceed in a manner beyond expectation. The contrivance is ſimply this. An axle, equal in length to the breadth of the ridge, is fixed upon two caſt wheels, to which are faſtened, by chains, as many harrows as are capable of covering the whole breadth of the ridge. Then two horſes are yoked, and one made faſt to each end of the axle, being made to walk in the furrows of the ridges; the wheels turning eaſily round ſo as to follow the horſes in the furrows, by which means the horſes' feet are prevented from doing any injury by poaching, and the ſeed equally covered as in the uſual method of harrowing. In this caſe care ſhould be taken not to turn the harrows ſhort at the ends of the ridges; to avoid which, the beſt method is probably that of going along one ridge and returning by the next, which ſhould be performed as often as may be found neceſſary for completing the work.

In the Agricultural Survey of Middleſex, it is complained that the buſineſs of harrowing is there a very tedious ſort of labour. The pace of the horſes is diſguſting, and one-fourth part of the time of the man who drives them, is taken up in unhitching them, which might be readily prevented by the means already noticed, and the uſe of whip reins in directing the animals, which ſhould have ſufficient length to permit the driver to walk behind the harrows, and which is a common practice on the borders of Scotland, as well as in the counties of Norfolk and Suffolk. It is contended that as a neceſſary conſequence they would harrow four times as much land in a given time as by their preſent mode, and that would be executed in a much better manner.

It is obvious, however, that the pace of the horſes muſt in a great meaſure depend upon the nature of the land and the harrow, yet the driving by long whip reins is without doubt a very great improvement in the performance of this ſort of farming labour. See TILLAGE.

HARRY ISLAND, in *Geography*, an iſland of the Atlantic, near the mouth of the Santee river, on the coaſt of South Carolina. N. lat. 33° 10'. W. long. 79° 12'.

HARSCHEF, in *Botany*, the name by which Avicenna, Serapion, and the reſt of the Arabian writers, call the *cinara*, or *artichoke*.

HARSEN'S ISLAND, in *Geography*, an iſland near the entrance of the river St. Clair, in lake St. Clair, E. of Thompſon's iſland, containing 500 acres of land fit for culture, the other parts being meadow and marſh.

HARSHGOONE, a bay on the coaſt of Algiers, between Cape Figalo and Cape Hone.

HARSO, a ſmall iſland in the Baltic, near the coaſt of Sweden. N. lat. 58° 44'. E. long. 17° 16'.

HART, in the *Foreſt Law*, a ſtag or male deer of five years old complete. See DEER and STAG.

If the king or queen hunt him, and he eſcape, he is called a *royal hart*.

And if by ſuch hunting he be chaſed out of the foreſt, proclamation is commonly made in the places adjacent, that in regard of the paſtime the beaſt has afforded the king or queen, none ſhall hurt or hinder him from returning to the foreſt; upon which he is called an *hart-royal proclaimed*.

Harts at one year old have no horns, but only bunches; and at two years they are very imperfect, being ſtraight and ſingle; at three years old they grow out into two ſpears; at four, into three; and ſo increaſe every year in number of branches, till they are ſix years old; but after that their age is not to be known by their heads. February and March are the months in which they caſt their horns; and, in general, the older ones caſt them ſooner than the young ones. Thoſe that have been injured at rut, or which have been gelded, never caſt them at all; if they are gelded while young, they never have any horns: if after their horns are grown, they keep thoſe which they had on at the time as long as they live. The horns of ſome are reddiſh, thoſe of ſome black, and thoſe of others finally are white. The red horns are generally the largeſt and ſtrongeſt, the black are uſually ſhorter, and the white are worſt of all, being the leaſt ſolid or ſtrong.

This animal is the moſt cunning in its care of itſelf of all the deer kind. It is the moſt timorous of any, and by its windings and turnings, and other ſubtilties, as the running among herds of cattle, often deceives the huntſman, and puts a foil upon the dogs. In the chaſe, which generally is a long one, he takes over hedge, ditch, river, or whatever comes in his way, nothing ſtopping him.

This creature loſes its horns in the ſpring-time, as the other deer do; but, during the time that it is without them, does not appear, but abides in the thick woods, and only comes out in the night-time for food.

HART-*clover*, in *Agriculture*, a common name applied to a plant of the melilot kind. See CLOVER.

It may be found beneficial in the way of an artificial graſs in ſome caſes.

HART-*hunting*. See HUNTING.

HART'S-*horn*, *cornu cervi*. See HART'S *Horn*.

HART'S-*horn*, in *Botany*. See PLANTAGO.

HART'S-*tongue*, *lingua cervina*. See ASPLENIUM.

Sea-HART'S *tongue*, *phyllitis marina*, in *Natural Hiſtory*, a name given by ſome authors to a ſpecies of marine ſubſtance, which, in ſome degree, reſembles the common hart's-tongue. It grows on the rocks at great depths, and is ſeldom ſeen, unleſs when taken up by the coral-fiſhers; its leaves are ſometimes ſingle, ſometimes they are divided into two; they are of a dulky green colour, and are about two inches in length; they have each a nerve or rib running along their middle; they are very thin and tranſparent, and are of a ſort of cartilaginous ſtructure, and each has ſeveral rows of ſmall points on each ſide of the middle rib, which not unaptly reſemble the ſeed ſpots on the leaves of ſome of the capillary plants; but not on thoſe of the *phyllitis*, or hart's-tongue, in particular, becauſe they are in that plant not round but oblong, and ſtand only in a ſingle row on each ſide of the rib. When this ſubſtance is viewed by the microſcope, it appears in all parts of the leaf full of little holes, and thoſe which are ſo plain to the naked eye, are no

no other way different from the imperceptible ones, but in that they are larger. See CORALLINE.

HART-*wort of Marſeilles*. See SESELI.

HART-*wort of Crete*. See TORDYLIUM.

HART-*wort, ſhrubby, Ethiopian*, is a ſpecies of the BUPLEURUM.

HART, or *Stag-evil*, in the *Manege*, a ſort of rheum or defluxion that falls upon the jaws, and the other parts of the forehand of a horſe, which hinders him from eating; ſometimes, alſo, this diſtemper affects the parts of the hinder quarters.

HARTANITHE, in the *Materia Medica of the Ancient Arabs*, was one of the names of the ſtruthium, or lanaria herba of the Greeks and Romans, a kind of thiſtle, the root of which was uſed in the cleaning of wool.

HARTFIELD, in *Geography*, a mountain of Scotland, in the county of Peebles, on the confines of Dumfrieſſhire, which, according to ſome accounts, is 3300, and by others, 2582 feet above the level of the ſea.

HARTFORD, a townſhip of America, in Windſor county, Vermont, on Connecticut river, in New Hampſhire; containing 1594 inhabitants.—Alſo, a poſt-town in Ontario county, on the E. bank of Geneſſee river, New York, 40 miles W. of Geneva; containing 535 inhabitants.—Alſo, a town in Cumbeland county, Maine, having 243 inhabitants.—Alſo, a fertile and populous, though hilly, county in Connecticut; bounded N. by the ſtate of Maſſachuſetts, S. by part of Middleſex and New Haven counties, E. by Tolland, and W. by Litchfield county; about 34 miles from N. to S. and at its greateſt breadth from E. to W. 30 miles. It is divided into 15 townſhips, and contains 42,147 inhabitants. Its chief town is Hartford.

HARTFORD *City*, the capital of Connecticut, on the W. bank of Connecticut river, in the county and townſhip of its own name, 50 miles N. W. from the mouth of the river; the townſhip is ſix miles ſquare. The town is divided by a ſmall ſtream, called Little river, with high romantic banks, over which is a bridge connecting the two diviſions of the town. It is regularly laid out, the ſtreets interſecting each other at right angles; the buildings are an elegant ſtate-houſe, two churches for Congregationaliſts, one for Epiſcopalians, and between four and five hundred dwelling-houſes; and contains 5347 inhabitants. A bank was incorporated in 1792. The town is well ſituated for trade, and is rich, flouriſhing, and commercial. It was ſettled in the year 1636; 223 miles N. E. of Philadelphia. N. lat. 41° 44′. W. long. 72° 50′.

HARTFORD, a county of Maryland.—Alſo, a poſt-town of Ohio county, Kentucky, 736 miles from Waſhington, having 56 inhabitants.

HARTFORD, *Eaſt*, a town of Hartford county, Connecticut, on the E. bank of Connecticut river, oppoſite to Hartford, chiefly conſiſting of one broad ſtreet, $1\frac{1}{2}$ mile in length, and containing 3057 inhabitants. On the different ſtreams which water the town are ſeveral mills; and it has alſo iron and glaſs works.

HARTHA, a town of Saxony, in the circle of Leipſic, 22 miles S. E. of Leipſic. N. lat. 51° 6′. E. long. 12° 50′.

HARTLAND, or HERTLAND, a market-town and pariſh in the hundred of Hartland, in the county of Devon, England, is ſituated at the north-weſt corner of the county on the coaſt of the Briſtol channel, on a neck of land called Hartland Point (deſcribed in old authors as Promontorium Herculis), and is bounded to the north by ſome boggy heights, where the rivers Tamar and Torridge have their ſource. From Hartland to Biddeford the land forms a bay, called Barnſtaple bay, ſo that theſe towns have but one port, which was made a ſea-port by act of parliament in the reign of queen Elizabeth. The church of Hartland is ſituated about a mile from the town, on a lofty eminence near the ſea. It is a large, handſome building, and conſiſts of a nave, two aiſles, and a chancel; the latter is divided from the body of the church by an ornamented ſcreen. The houſes in this pariſh, as returned under the late act, amount to 287; the inhabitants to 1546. A market, held here on Saturdays, is much frequented, particularly by the fiſhermen of Barnſtaple, Biddeford, and other towns on the coaſt. Hartland is diſtant from London 116 miles.

In the vicinity of the town is Hartland abbey, the ſeat of Paul Orchard, eſq. The preſent building includes the ſcite and ſome portion of the ancient abbey, ſaid by Camden and other writers, to have been founded by Githa, wife of earl Godwin. Polwhele's Hiſtory of Devonſhire, folio.

HARTLAND *Point*, a cape of England, on the N.W. coaſt of the county of Devon, in the Briſtol channel. N. lat. 51°. W. long. 4° 26′.

HARTLAND, a townſhip of America, in Connecticut, the north eaſternmoſt of Litchfield county, containing 2318 inhabitants.—Alſo, a poſt town in Windſor county, Vermont, on the W. bank of Connecticut river, containing 1960 inhabitants.

HARTLEPOOL, a market town in the pariſh of Hart and ward of Stockton, county-palatine of Durham, England, is a ſea-port and member of Newcaſtle. It is ſituated on a promontory, nearly encompaſſed by the German ocean, which, on the ſouth ſide of the town, forms a capacious bay. This is a very favourable place for landing troops, and hence, in the time of the Norman dynaſty, its harbour was much frequented. The town was then protected by fortifications. A market was ſecured to this place by Wm. de Bruce; and king John, in the ſecond year of his reign, granted to the free-burgeſſes of Hartlepool the ſame liberties and privileges as were enjoyed by the burgeſſes of Newcaſtle. The town thus obtained importance, but it was additionally improved by Robert de Bruce, grandſon of the above named William, who built a "haven, and a wall about the town, with ten towers on each ſide of the haven, and a chain to be drawn between them near the haven; which haven would hold 100 ſayle" of veſſels. "Few places in the kingdom," obſerves Hutchinſon, "give ſo perfect an idea of the fortifications of former times as Hartlepool. A long extended wall, ſtrengthened by demi-baſtions, at intervals, ſome rounded, others ſquare; various gates and ſally-ports, ſecured by machicolations, and the portcullis, ſome of the gates defended by angular, others by ſquare turrets; all the variety appearing which had grown into uſe in that age." Theſe walls, fortifications, &c. are minutely deſcribed by this author, and ſince his account was written, the whole has undergone a complete repair, and the harbour placed in a ſecure, or defenſible condition. This town is chiefly built on the weſtern ſide of a hill; and in the ſummer months is much frequented by viſitors for the purpoſe of ſea-bathing. The ſurrounding country is picturеſque and intereſting. North of the town, the coaſt is ſkirted with rocks, which are rendered cavernous by the violence of the waves, and preſent many romantic ſcenes at low water. The public buildings of the town are a chapel, town-hall, free-ſchool, and cuſtom-houſe. The civil government is veſted in a mayor, recorder, aldermen, and common-council. In 1800 this townſhip contained 230 houſes, with a population of 993 perſons. On the ſouth ſide of the town is a ſpring of chalybeate water, which is ſubmerſed by the ſea at every tide. About five miles

miles north of Hartlepool is a very ſingular and romantic cluſter of rocks, in the numerous caverns called the Black Holes. Some of theſe rocks are detached from the ſhore, others have been entirely ſwept away by the tides, and ſome are perforated, and aſſume an arched appearance. Near the town are ſome collieries. Here is a ſmall weekly market, and four annual fairs. Hutchinſon's Hiſtory and Antiquities of Durham, 3 vols. 4to. A wide ſhort canal falls into Hartlepool harbour.

HARTLEY, DAVID, in *Biography*, an eminent phyſician, and a profound moral and metaphyſical writer, was the ſon of a worthy clergyman, the vicar of Armley, near Leeds, in Yorkſhire, and was born on the 30th of Auguſt, 1705. He was admitted of Jeſus college, Cambridge, at the age of fifteen; he took the degree of M. A., and ultimately became a fellow of his college. His earlier ſtudies were conducted with a view to taking orders; but upon a more cloſe conſideration of the terms of clerical conformity, ſerious and inſurmountable ſcruples aroſe in his mind againſt ſubſcription to the thirty-nine articles of religion. Feeling, therefore, that he could not enter into the national eſtabliſhment without doing violence to his conſcience, he relinquiſhed all thoughts of the clerical profeſſion; but he ſtill continued to the end of his life in communion with the church of England, approving of its practical doctrines, and conforming to its public worſhip. He now determined to enter upon the ſtudy of medicine, for which his talents and the ſenſibility and humanity of his diſpoſition equally fitted him. "His mind was formed to benevolence and univerſal philanthropy;" ſays the author of the ſketch of his life and character, "he exerciſed the healing art with anxious and equal fidelity to the poor and to the rich. He viſited with affectionate ſympathy the humbleſt receſſes of poverty and ſickneſs, as well as the ſtately beds of pampered diſtemper and premature decrepitude. His manners were gentle; his countenance affable; his eloquence moral and pathetic." He commenced the practice of phyſic at Newark, in Nottinghamſhire; whence he removed to Bury St. Edmund's, in Suffolk: after this he ſettled for ſome time in London; and finally went to Bath, where he ſpent the remainder of his life, and died in the year 1757, at the age of 52.

Dr. Hartley was the author of ſome medical tracts relative to the operation of Mrs. Stephens's medicine for the ſtone, a diſeaſe with which he was himſelf afflicted: he was, indeed, principally inſtrumental in procuring for Mrs. Stephens the five thouſand pounds, granted by parliament for diſcovering the compoſition of her medicine, which was publiſhed in the gazette in June, 1739. In 1738 he publiſhed "Obſervations made on ten Perſons who have taken the Medicament of Mrs. Stephens;" and in 1739 his "View of the preſent Evidence for and againſt Mrs. Stephens's Medicine as a ſolvent for the Stone, containing 155 Caſes, with ſome Experiments and Obſervations," and a "Supplement to the View of the preſent Evidence, &c." His own caſe is the 123d in the above-mentioned "View:" but notwithſtanding any temporary relief which he might receive from the medicine, he is ſaid to have died of the ſtone, after having taken above two hundred pounds weight of ſoap, which is the principal ingredient in its compoſition. In the gentleman's magazine for February, 1746, Dr. Hartley publiſhed, with his name, "Directions for preparing and adminiſtering Mrs. Stephens' Medicine in a ſolid Form." Dr. Hartley is ſaid to have written in defence of inoculation for the ſmall-pox, againſt the objections of Dr. Warren, of Bury St. Edmund's; and ſome papers of his are to be met with in the Philoſophical Tranſactions. Haller informs us that ſeveral letters from him, in correſpondence with Moraud, were inſerted in a "Collection" printed at Paris in 1740, 12mo.

But the principal work of Dr. Hartley, upon which his fame with poſterity ſecurely reſts, is the great metaphyſical treatiſe, which he preſented to the public in 1749, under the title of "Obſervations on Man, his Frame, his Duty, and his Expectations, in two parts," 8vo. The doctrine of vibrations, indeed, upon which he attempts to explain the origin and propagation of ſenſation, although ſupported by much ingenious reaſoning, is not only built upon a gratuitous aſſumption, but, as Haller has ſhewn, it attributes properties to the medullary ſubſtance of the brain and nerves, which are totally incompatible with their nature. The metaphyſical parts of this work, however, and more eſpecially his diſquiſition reſpecting the power of aſſociation, are monuments of great ſubtlety of reſearch, and of profound knowledge of the operations of the human mind. The moſt valuable edition of this work was publiſhed in 1791, 4to. with a ſketch of the life and character of the author, by his ſon David Hartley, including notes and additions to the ſecond (or moral and religious) part of his doctrines, tranſlated from the German of the Rev. Herman Andrew Piſtorius, rector of Poſeritz, in the iſland of Rugen. See Gen. Biography. Ann. Reg. 1775. Sketch prefixed to the edition of 1791.

HARTLEY, or *Hartley-Pans*, in *Geography*, a ſea-port and townſhip in the pariſh of Earſdon caſtle-ward, Northumberland, England, contained, in the year 1800, 348 houſes, and 1639 inhabitants. A harbour has been recently made at this place, chiefly at the expence of lord Delaval. The artificial baſon meaſures about 900 feet in length, by 30 feet in breadth, and is more than 40 feet deep. This harbour is moſtly uſed by coal veſſels, which carry this fuel from "Delaval's Hartley-Main" to the metropolis. Hartley is five miles north of Shields; and near it is Seaton-Delaval, a noble manſion, built by ſir John Vanburgh, for the Delaval family. Though ſmall, if compared with the ſpacious palace of Blenheim houſe, yet the manſion at Seaton is a fine and intereſting ſpecimen of ſir John's ſtyle of architectural deſign.

HARTMAN, GEORGE, in *Biography*, a German mathematician, who flouriſhed in the 16th century, invented what is denominated the artillery-ſtaff, "Baculus bombardicus," for the uſe of engineers. He was author alſo of a "Treatiſe on Perſpective," of which an improved edition was publiſhed by Paſquier du Hamel, at Paris in 1556.

HARTMAN, JOHN ADOLPHUS, was born at Munſter in the year 1680, and educated in the principles of the Jeſuits, into whoſe ſociety he was entered while he was very young. In 1715 he renounced the papal communion, and united himſelf to the Calviniſts at Caſſel, ſoon after which he was appointed profeſſor of philoſophy and poetry. In 1722 he was created profeſſor of hiſtory and eloquence at Marpurg, where he died in 1744. He was the author of many works, but the principal are, "Vitæ Pontificum Romanorum, Victoris III., Urbani II., &c." "The ſtate of ſciences at Heſſe:" "Precepta Eloquentiæ Rationalis, &c." He publiſhed likewiſe more than eighty academic diſſertations.

HARTMANN, JOHN, a phyſician, was born at Amberg, in Bavaria. In the year 1591 he began to teach philoſophy and mathematics at Marpurg, where he took the degree of M.D. in 1606, and was appointed profeſſor of chemiſtry in 1609, being the firſt who publicly taught that ſcience there. He entered upon this office with great ardour, and his method of teaching procured him great repu-

tation; insomuch that the landgrave of Hesse commanded him to settle at Cassel, in order to attend his person as chief physician. He removed thither accordingly, though not without great reluctance at quitting his chair, in the year 1616, and continued there until his death, which took place on the 7th of December, 1631. He left the following works: "Philosophus, sive naturæ-consultus Medicus, Oratio, &c." Marpurg, 1609. "Disputationes chymico-medicæ, sub ejus præsidio censuræ expositæ," ibid. 1611. "Praxis Chymiatrica," Leipsic, 1633; a posthumous work, edited by his sons, which passed through many editions. The following were also posthumous: "Diatribe de usu medico Microcosmi, &c." Erfurth, 1635. "Tractatus physico-medicus de Opio," Witteburg, 1635 and 1658. "Anthropologia physico-medico-anatomica," Venice, 1696. A collection of his works under the title of "Opera omnia Medico-chymica," was edited at Francfort, 1664 and 1690, by Conrad Johren. Eloy. Dict.

HARTOGIA, in *Botany*, so named by Thunberg and the younger Linnæus, in memory of Hartog, a Dutch botanical traveller, by whom many plants from the Cape of Good Hope were first made known to European collectors. (The original *Hartogia* of Linnæus being referred to *Diosma*, the present was chosen by Thunberg, who nevertheless, by an unaccountable error, subsequently mistook it for the real *Schrebera schinoides* of Linnæus, as did Jussieu. The latter genus however is a nonentity, appearing by his herbarium to be *Cuscuta africana* of Willdenow, growing on *Myrica æthiopica*, and therefore another *Schrebera* was founded by Retzius, which turned out a *Celastrus*, the *glaucus* of Vahl, Symb. fasc. 2. 42. Finally a very noble and distinct *Schrebera* is, we hope, established beyond further perplexity, by the late learned and excellent Mr. Dryander, in Roxburg's Plants of Coromandel, v. 2. 1. t. 101: see SCHREBERA.) —Linn. Suppl. 16. Thunb. Nov. Gen. 86, with a figure. Schreb. 81. Willd. Sp. Pl. v. 1. 669. Mart. Mill. Dict. v. 2. Lamarck. Dict. v. 3. 77. Illustr. 307. t. 76. (Schrebera; Thunb. Prod. part 1. n. 12,)—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Dumosæ*, Linn. *Rhamni*, Juss.

Gen. Ch. *Cal.* Perianth inferior, in four (not five) deep, spreading, roundish, acute segments, deciduous. *Cor.* Petals four, alternate with the calyx and twice as long, equal, obovate, concave, inserted under a glandular four-lobed receptacle, or nectary. *Stam.* Filaments four, awl-shaped, ascending, shorter than the petals, inserted between the lobes of the nectary; anthers vertical, ovate, furrowed. *Pist.* Germen superior, ovate; style short; stigmas two, divaricated, cloven. *Peric.* Drupa dry, ovate. *Seed.* Nut solitary, containing two kernels.

Ess. Ch. Calyx in four deep segments. Petals four. Nectary a four-lobed gland. Stigmas two, cloven. Drupa with a two-seeded nut.

1. H. *capensis*, the only known species. Linn. Suppl. 128. (Schrebera schinoides; Thunb. Prod. 28. t. 2.)—Native of woods at the Cape of Good Hope. A *shrub* five or six feet high, variously branched, smooth. *Leaves* opposite, two inches long, elliptic-lanceolate, obtuse, serrated, smooth, veiny; entire at the base, and tapering down into a bordered footstalk. *Flowers* small, in short axillary, drooping clusters or panicles. *Fruit* oval, the size of a pea, roughish, but destitute of pubescence.—We cannot account for Thunberg's defining the calyx as five-cleft, which other authors copy from him; while in his own excellent figure in his *Prodromus*, and even in that of his *Nova Genera*, as far as any thing can be made of it, the calyx is four-cleft, the petals being four; according to the analogy of the natural order to which the plant belongs.

HARTOGIA, Linn. Gen. 108; Sp. Pl. 288. See DIOSMA.

HARTSOCKER, NICHOLAS, in *Biography*, was born at Gouda, in Holland, in the year 1656, and intended by his father for the profession of a remonstrant minister, but the son shewed a very early disposition to study the works of nature, and his principal pleasure consisted in contemplating the stars and planets, and in consulting all the almanacs that he met with. Finding, however, that he could not understand the theory of the one, nor the construction of the others, without some degree of mathematical knowledge, he hoarded up the little money allowed him for his pocket, to pay an instructor for communicating to him the principles of this science. He now assiduously applied himself to his favourite studies, and particularly to the study of the microscope. By his observations with this instrument, which he improved, he made many discoveries, particularly with respect to the animalcula found in the semen of male animals. When he was about eighteen years old, he devoted, at the desire of his father, some years to the studies of the belles lettres, and other subjects connected with general literature, under the ablest masters at Leyden and Amsterdam. He embraced the Cartesian doctrines which he afterwards abandoned, and while he was at Amsterdam he had an opportunity of being introduced to M. Huygens, who took him as a travelling friend and companion to Paris. Here he met with M. Cassini, who foretold that the young philosopher would become very great if he proceeded in the path in which he had set out. Encouraged by the good opinion of so able an astronomer, he undertook to make some improvements in the glasses made use of in the observatory, and accordingly, with his own hand, constructed and ground excellent lenses of various sizes, one of which had a focus of six hundred feet. In 1694 he published "An Essay on Dioptrics," which was not only well received but procured him the esteem of many men of learning, particularly of father Malebranche and the marquis de l'Hôpital. His next work was entitled "The principles of Natural Philosophy." He was elected member of several foreign learned societies, and was invited by the czar Peter I. to assist him in his mathematical studies, but M. Hartsocker did not accept the invitation, chusing rather to remain in his native country. The magistrates of Amsterdam, as an acknowledgment of the honour which he had done to Holland, in his preference of it in opposition to the high honours of a great emperor, erected for his use a small observatory on one of the bastions of the city. In 1704, after three years solicitation, he repaired to the court of the prince elector palatine, John William, by whom he was appointed his first mathematician, and honorary professor of philosophy at the university of Heidelberg. In 1607-8, he published the lectures which he had read to the elector palatine, under the title of "Physical Conjectures." Upon the death of the elector, he removed to Utrecht, where he undertook a course of natural philosophy, and where he ended his days in the year 1725. In the year 1730, his "Course of Natural Philosophy" was published with additional pieces on physics and observations from the letters of Leeuwenhoeck. Moreri.

HARTY, in *Geography*, a small island of England, at the S.E. end of the island of Sheppey, from which it is separated by a narrow channel, and from the main land of the county of Kent, by the river Swale. It is entirely pasture land, and maintains about 4000 sheep. It is a parish, and contains

contains a church; and has a ferry acroſs the Swale, a little N. of Faverſham.

HARTZ, or HARZ, a mountain and foreſt of Germany, riſing in the form of an amphitheatre, and extending from the bailiwick of Landgelſheim, in the principality of Wolfenbuttle, and the county of Goſzlar, through the E. part of the principality of Grubenhagen, a part of the county of Weonigerode, and the principality of Blankenburg, to the counties of Hohnſtein and Stolberg, as far as Hartzgerode, in the principality of Anhalt; being in length forty-eight miles, and in breadth about twenty. The mountains of the Hartz are otherwiſe called the Boſchea or Blockſberg; the higheſt being what is called the Great Blockſberg, which, (while the others are covered with wood, thus uniting the ancient confuſion of foreſt and mountain,) only preſents white ſtinted bruſh-wood; and the ſnow ſometimes remains till Midſummer, and even longer in the northern cavities. On the ſummit is a ſmall hovel, as a retreat for thoſe who aſcend. The height of the Great Brocken is by the barometer 3021 feet, and that of the Little Brocken 2713. The mountain of Blockſberg conſiſts chiefly of grey granite. Although rain, ſnow, and fog are more prevalent on the Hartz mountains than in the level country below it, they do not ſeem to affect the longevity of the inhabitants, if we except thoſe who are occupied in the mines and forges. The whole harveſt of theſe higher regions conſiſts of good hay, other productions of the ſoil, however cultivated, ſeldom ripening. The foreſt conſiſts of about one-third of hard wood; *viz.* oak, beech, aſh, aſpen, alder, birch, &c. and two-thirds of ſoft wood, ſuch as firs and pines. The timber is peculiarly uſeful, as it ſerves the purpoſes of the mines and forges. The minerals found here are yellow ochre, vitriol, ſalt-petre, ſulphur, and lapis calaminaris; together with cobalt, lead, borax, iron, copper, ſilver, and ſome gold. The ſilver mines of the Hartz were the firſt that were ever opened in the north of Europe. Some ſay they were firſt diſcovered in the year 968, and wrought by the command of the emperor Otho the Great. According to others, they were accidentally diſcovered in the tenth century by a hunter, whoſe horſe tied to a tree ſtruck with his feet and diſcloſed the mineral. The rock is gneiſs. The Hartz, and alſo its mine-works, are divided into Upper and Lower. The inhabitants of the Hartz conſiſt of miners, labourers in the ſmelting-houſes, wood-hewers, carriers, and the ſovereign's officers and ſervants; together with miniſters, ſchool-maſters, artificers, handicraft's-men, and tradeſmen, to whom are aſſigned certain immunities and privileges. The Hartz, and its mines, were formerly the joint property of the electorate of Hanover and of the duke of Brunſwic; but the ſhare of the latter has been more recently exchanged with Hanover for another diſtrict. The clear annual product of the mines is computed at 453,000 dollars, the dollar being eſtimated at 3*s.* 4*d.*

HARTZEIN, JOSEPH, in *Biography*, who flouriſhed in the eighteenth century, was deſcended from a patrician family at Cologne, and born in that city about the year 1694. He was firſt noticed in public life as an inſtructor in the belles-lettres, in the ſeminaries of his order; after which he was elected profeſſor of the learned languages at Milan. He next diſcharged the duties of confeſſor, preacher, and profeſſor of theology; and he alſo officiated as interpreter of the ſcriptures, publiſhing annually diſſertations which were well received by the learned world. He publiſhed "A Collection of the Councils of the Church of Germany," in four vols. folio, which had been begun by father Schannat. Hartzein was preparing a fifth volume for publication, when his labours were put an end to by an apoplectic fit, in the year 1763. He was author of many other learned works; particularly "Summa Hiſtoriæ omnis ab Exordio Rerum ad Annum à Chriſto Nato:" "Bibliotheca Scriptorum Colonienſium:" "Diſſertationes X Hiſtorico-criticæ in Sacram Scripturam."

HARTZGERODE, in *Geography*, a town of Anhalt-Bernberg, near the Hartz mountains; the houſes and walls are conſtructed of a motley kind of marble. It has a mine-office and caſtle; 24 miles S.W. of Bernburg. N. lat. 51° 40′. E. long. 11° 20′.

HARVA, a town of Sweden, in Weſt Gothland; 15 miles E. of Gotheborg.

HARVARD, a townſhip in the eaſtern part of Worceſter county, Maſſachuſetts; 23 miles N.E. of Worceſter; incorporated in 1732, by this name, in honour of the founder of Harvard univerſity, in *Cambridge*, (which ſee,) and containing 1400 inhabitants.

HARVEST, in *Agriculture*, a name which is commonly applied to the ſeaſon in which grain, hay, and other crops are cut down, carried and ſecured in the barns or ſtack-yards.

The particular period at which the harveſt for corn and hay takes place, is ſooner or later according to the nature and ſtate of the climate, the qualities of the ſoil, and the peculiar circumſtances of the crops in regard to ſituation and kind. In the more northern diſtricts, the harveſt for both hay and corn is, however, in general, later by a month or ſix weeks than in thoſe of the ſouth. The hay-harveſt is very rarely completed before that of the grain is commenced, though in ſome it is pretty nearly the caſe.

HARVEST *Beef*, a term uſed to ſignify the meat conſumed by harveſt-men, whatever the nature of it may be.

HARVEST, *Corn*, a term ſignifying the time at which grain becomes ready for the ſickle, and fit to be cut down and preſerved in ſome way or other. It has been obſerved that the difference in the periods at which the corn-harveſt uſually commences in the different diſtricts of the kingdom, is very conſiderable, being probably greater than what happens in any other country of the ſame extent in Europe. There is ſcarcely one diſtrict that does not vary from another in this reſpect, ſo that the common duration of the harveſt in this country cannot be conſidered leſs than three months. It is uſually begun in the ſouthern and midland parts of the kingdom, towards the end of July, and the beginning of the following month; but in the northern diſtricts of Scotland, not until the firſt or ſecond week in September. And it is but rarely, that in theſe laſt ſituations it is finiſhed even in the moſt favourable ſituations, before about the end of October; and it not unfrequently happens that it is the middle of the ſubſequent month before it is wholly completed.

It may likewiſe be noticed that the periods are ſcarcely more various at which the harveſt begins in different parts of this country, than the modes are, in which the ſeveral different operations of that buſy ſeaſon are executed. In ſome caſes it is the cuſtom to reap or cut the corn with a ſickle, and bind it up into ſheaves of a moderate ſize; in others the cutting of the grain is executed by the ſcythe in ſome particular method or other, and often left without being bound up, though, in ſome caſes, it is bound into a ſort of bundles.

And further, in ſome inſtances a toothed ſickle is employed, while in others a ſickle with a cutting-edge is made uſe of for the purpoſe. The grain, when reaped or mown, is in many caſes ſet up into ſome ſort of hattock, and capped or covered with ſheaves of the ſame; but in others this is not by any means the caſe. In ſome inſtances, alſo, the grain is

cut high, ſo as to leave a rough ſtubble, while in others, again, it is cut quite cloſe to the ſurface of the land. See Reaping.

In the Rural Economy of Yorkſhire, it is ſtated that there is no department of it that diſtinguiſhes the northern from the ſouthern and midland parts of the iſland ſo greatly as that of the method of performing the harveſt-work. And further, that probably none of the northern diſtricts are more ſtrongly marked with this diſcriminating characteriſtic than this. It is probable that nine-tenths of the corn that is cut within the kingdom is executed by men. In the counties of Surry and Kent, a woman may ſometimes be ſeen with a ſickle in her hand. But in Norfolk it is a ſight that is very rarely to be met with. Here, however, it is equally rare to notice a ſickle in the hand of a man, reaping, or provincially, ſhearing, being almoſt wholly performed by women. And three women and one man conſtitute what is termed a ſet, which, if the crop be a middling one, are capable of executing an acre a day. Where the corn is thin, one man is ſufficient to bind after four women; but where it is very thick upon the ground, he requires to have the aſſiſtance of a boy to make bands for him.

It is the practice in ſome caſes, to have the bands laid for the women to place their handfuls in, but more generally the corn is laid in heaps of about half a ſheaf each, the binder gathering them up carefully againſt his legs, in a ſimilar manner to that in which wheat ſtraw is uſually gathered upon the threſhing-floor. And this is much the beſt method, though ſomewhat more troubleſome, the corn being by this means bound up in a tight and even manner, the ſheaves being formed in an equal ſized manner.

The day-wages were, formerly, for a woman, during the harveſt, 10*d.* *per* day, and 2*s.* *per* day for a man. Conſequently at that time, wheat, which in the county of Surry would coſt 10*s.* or 12*s.*, and which, in any other county, would not be leſs than from 7*s* to 8*s.* would be in this diſtrict, (Yorkſhire,) cut for 4*s.* 6*d.* the acre.

It muſt be noticed, however, that within a few years the price of labour has greatly advanced, ſo that from 1*s.* 3*d.* to 1*s.* 6*d.* *per* day for a woman, and from 3*s.* to 3*s.* 6*d.* *per* day for a man, may probably, at preſent, be not far from the average price that is paid for harveſt labour. It is, however, conceived, that the ſaving of ſo much an acre is far from being the only benefit that is derived from the practice of employing women in the buſineſs of harveſt; the number of hands is multiplied; the poor man's income is increaſed; the parochial rates are leſſened; and the community in general are benefited by the diffuſion of the habit of induſtry, and the acquiſition of health. "How conducive to this, ſays the writer, are the employments of huſbandry compared with thoſe of manufactures! and the work of harveſt, ſo far from being thought a hardſhip, is, by women who have been bred to it, conſidered as a relaxation from domeſtic confinement and leſs agreeable employments."

The great change of circumſtances which has lately taken place in the country, has, however, rendered the employment of women in harveſt-work much leſs frequent than was formerly the caſe in moſt of thoſe diſtricts where they were formerly had recourſe to, and even in Yorkſhire this is much the caſe.

Harvest *Fly*, in *Natural Hiſtory*, the name of a large fly, remarkable for the noiſe which it makes in the ſummer months, and particularly about the time of harveſt. See Cicada.

Harvest, *Hay*, in *Agriculture*, that ſort of harveſt which relates to the buſineſs of converting graſs-crops into hay. See Hay and Hay-*Making*.

Harvest *Home*, the name of a ſort of feaſt that was formerly frequently given by farmers to their labourers and others, who were employed in the cutting and ſecuring the crops, at the cloſe of the buſy ſeaſon of harveſt. It is a cuſtom that does not prevail to any great extent at preſent. It is alſo occaſionally made uſe of to ſignify the ſong that is uſually ſung on the occaſion of this happy event.

Harvest *Labour*, that ſort which is practiſed in the field during the period of harveſt; comprehending the operations of reaping, mowing or cutting, and ſecuring crops of the grain kind.

Harvest *Men*, the name of thoſe labourers who are employed for the purpoſe of executing harveſt-work. In the engaging of this ſort of labourers, different methods are had recourſe to by the farmer, according to the nature of the circumſtances, ſituations, and ſeaſons; but at preſent, the moſt economical method is, probably, to let them have the work by the acre, ſo as to perform every thing which has any relation to it. It is, however, the practice in ſome places to hire them by the month, keeping them during the time in the houſe; in which way, though it may be very expenſive, the men are conſtantly at hand.

It has been ſuggeſted, that the victualling of harveſt-men, as practiſed in the county of Glouceſter, is extremely judicious and proper. They have no regular dinner. Their breakfaſt is cold meat. Their refreſhment in the field bread and cheeſe, with ſix or eight quarts of beverage. And at night, when they return home, they have a hot ſupper, after which each man has a quart of ſtrong beer, in order to alleviate the fatigues of the day which has elapſed, and to ſend him to reſt in good humour and ſpirits, by which he is prepared for the toil of the enſuing day. It is further ſuppoſed, that more than one advantage ariſes from this cuſtom. "All the work within doors, in the middle of the day, is got rid of; and the importance of continuing the work of the field, without a break through the prime part of it, is extremely evident, and capable of being properly appreciated by thoſe who from experience know how to value it.

It is, however, now moſtly the cuſtom in different parts, for the harveſt-men to have a dinner of meat in the middle of the day, either at home or in the field where they are at work, with as much ſmall and ſtrong beer as they can drink.

In the diſtrict noticed above, the hours of labour are very long, generally, where diſpatch is required, from dawn to duſk. And the quantity of work that is done is commonly above par, that is, from twenty to thirty loads of grain with one ſet of men. In moſt places, the rule is to begin as ſoon as they can ſee, and to work until the night falls.

Harvest-*Month*, a term applied to the time for which harveſt men are in general hired.

Harvest *Moon*. See Moon.

HARVESTING, the act of cutting down and ſecuring different ſorts of harveſt crops, ſo that they may be kept until they are wanted for uſe. There are various modes of effecting this kind of buſineſs; indeed, peculiarities are found attached to almoſt every different tract in the manner of executing it, ſome of which, if they were attempted to be introduced into others, would be conceived improper in many, and in ſome quite abſurd.

If it were, for inſtance, adviſed that, in Sutherland and Caithneſs in Scotland, the cultivators of the land ſhould purſue the methods of mowing and harveſting the grain in ſwath, or in cocks, that are practiſed in many of the counties of England, it would unqueſtionably expoſe the adviſer to the ridicule and contempt of thoſe who are more perfectly acquainted with the matter.

HARVESTING.

It muſt be evident, to every one who is converſant with the ſubject, that the manner of harveſting a crop that does not become perfectly ripened before October or November, ſhould, in conſequence of the uſual precarious ſtate of the weather at ſuch a ſeaſon, be very different, and that much more care and precaution are requiſite to preſerve it from injury than what is neceſſary for the purpoſe in July and the following month, when the days are ſo much longer, and the influence of the ſun ſo much greater. But this, though it does not by any means account for all the various methods in which the crops of grain are harveſted in the kingdom, many of which are probably continued rather in conſequence of long habit and the early prejudices of farmers, than from any conviction of their expedience, may, notwithſtanding, afford a pretty ſatisfactory reaſon why more precaution is required in the more northern parts of the iſland than is conceived neceſſary in the ſouthern and eaſtern diviſions of the country. In the latter of theſe, as has been already ſeen, the harveſt begins at an early period, and the farmer has, of courſe, but little to apprehend from long continued ſeaſons of unfavourable weather, or the rapid approach of the winter, which oppoſes numerous difficulties.

In whatever mode the work of harveſting is managed, it is clear that, as bad weather muſt greatly affect the profits of the cultivator, eſpecially where wheat-crops are concerned, it is proper that he ſhould be conſtantly on his guard to have a ſufficient number of hands at work, in order that the moſt may be made of the fine ſeaſon; for, without this, much loſs muſt be ſuſtained, and the title of *afternoon farmer* be applied to him. Indeed, when the weather is favourable at this period, there ſhould never be a ſingle moment loſt in getting forward with the work, as a proper degree of diſpatch is every thing.

With regard to the cutting of the crops, it is neceſſary to ſtate, that moſt ſorts of grain, except that of barley, ſhould be cut or reaped before they become over-ripe. But where barley is cut in an unripe condition, it is apt to ſhrivel, and become a bad ſample. It is, however, a practice with ſome farmers to leave the corn ſtanding ſuch a length of time, that it is ripe enough to *cut* and *carry*, as they term it, or until the ſheaves are capable of being carted home, on being bound up. This method can, however, only be purſued where the crops are quite clean and free from all ſorts of weeds.

It is ſtated, in the Report of Eaſt Lothian in Scotland, that the harveſting with winter-ſown wheat is ſometimes earlier than for other kinds of grain, only excepting Dutch oats. Spring-wheat is later, and, unleſs in favourable ſeaſons, is cut with other grains. It is, however, ſuggeſted, that there ſeems to be ſome diverſity of opinion among the farmers of this diſtrict, concerning the marks of ripeneſs in wheat, or the exact degrees of it that are requiſite to conſtitute a perfect ſample: ſome aſſert that cutting quick or early is the ſureſt mode of having the grain perfect; but others, on the contrary, are of opinion that it ſhould be dead ripe; or, in other words, that the circulation in the ſtraw, as well as the corn, ſhould be over before it is cut down. It is probable that the truth is to be found in the middle between theſe extremes; as the opinion is ſanctioned by the practice of the beſt farmers, who neither cut very quick, nor allow the wheat to be over ripened. Attentive obſervation readily points out the marks of maturity which are neceſſary for wheat, as well, indeed, as for every other ſort of grain, and which, when well conſidered, are ſanctioned by experience. As long as the circulation continues through the ear of the plant, the grain is deriving ſomething from the ſoil, and ſhould not be cut down; but the moment that is over, the ſooner it is cut down the better. The firſt appearance of the circulation being at a ſtand, conſiſts in a ſhrinking and whitening of the ſtrawy part immediately below the ear, which proceeds in a gradual manner downwards, until it reaches the bottom, when the grain is provincially ſaid to be *dead ripe;* in which ſtate the ſtraw becomes brittle, the ears are eaſily broken off, and the grains ſhake out in the time of handling. But to this ſtage it ought never to be allowed to come, as the loſs of grain is not only great, even under the moſt favourable circumſtances of calm and fair weather, but the quality is materially impaired by ſuch a long unneceſſary expoſure to the operation and influence of light and heat. It is a fact now well underſtood, that the nouriſhing and fermentable properties of all vegetable productions, whether grain or fruit, bear an exact proportion to the quantity of light and heat they have enjoyed during their growth and ripening; the benefits derived from theſe continue to be felt while the circulation goes on: but as ſoon as it ceaſes, theſe elementary ſubſtances begin to take away again what they had given formerly; the grain, of courſe, loſes its colour and flavour, and has every valuable quality diminiſhed. If it ſhould be overtaken by rain in that ſtate, the injury is infinitely greater than what happens to grain that is cut at an earlier period.

It would, conſequently, appear that the period at which wheat, and, in ſhort, all the other ſorts of white crops ſhould be cut, is when the ſtraw begins to ſhrink, and becomes white about half an inch below the ear; the circulation is then cut off, and all further benefit from its ſtanding is at an end; the grain has, in fact, taken every thing that is requiſite to perfect it from the ground; and as far as the value of the ſtraw, whether for fodder or other purpoſes, is concerned, an advantage is gained by cutting it while the circulation is going on, and by that means preſerving a part of the natural juices; the value of ſtraw, like that of hay, depending upon the proportion of natural juices it contains, and the pains which have been taken to preſerve them.

It is moſtly adviſed that ſuch wheat as is much infeſted with weeds, ſhould be cut three or even four days earlier than is uſual, in order that the weeds may have time to wither before the corn becomes too ripe, for if it ſhould not be cut before the grains are fully ripe, it will be liable to ſuſtain conſiderable injury by ſhedding, loſs of colour, and damage from rain, while it continues expoſed for the purpoſe of the weeds being rendered dry. A ſingle ſhower, or even a day's gentle rain, while it lies in ſwath, is, indeed, thought by ſome to be rather beneficial to the grain, by cauſing it to feel dry, and ſlippery in the hand, and threſh out the better; but every poſſible care ſhould at the ſame time be taken to guard againſt its being wetted too much in the field. When, however, through any unavoidable accident, it is laid up in too moiſt a condition, though it may not take any great harm in the mow, it will ſweat and adhere together, after being laid in a heap, when threſhed out, and have a perfectly white appearance from mouldineſs, as if dredged over with flower. As corn, in this ſtate, is not capable of being kept, it ſhould conſtantly be ſent to the market, and diſpoſed of as ſoon as poſſible.

Notwithſtanding it is ſuppoſed that moſt ſorts of grain are bettered by lying a ſhort ſpace of time in ſwaths, grips, or handfuls, in order to take the dews, which are believed to contribute to the rendering of the corn more plump, and of a better colour, yet the ſtraw is thereby greatly deteriorated as a fodder, unleſs the grain had been cut before it had attained its full maturity, and has laid out no longer than till it has become completely ripened.

ripened. But in hot dry ſummer ſeaſons, when the grain ripens in a complete manner, and its own vigour ſupplies it with a proper colour, rendering it ſo plump as that the huſks readily yield their contents on threſhing, wheat need not lie out in the above ſtates before it is ſheaved, unleſs it ſhould have much graſſy matter among it, which ought never to be the caſe; in cold wet ſummers, however, wheat is ſometimes horny and pale, the grains thin, and in need of being plumped up; their huſks adhering ſo cloſe, that they require to be mellowed in order to their threſhing in a proper manner. The full grain which ſwells the chaff, even until it opens in fine fruitful years, is almoſt bare and expoſed to the conſtant effects of moiſture, the heavy ears in ſuch caſes ſpreading and hanging over the chaff, which of courſe opens and ſpreads wider, letting the rains in at the bands more expeditiouſly than in leſs kindly ſeaſons, when the grain is more light, and the ears in the ſhock ſtand more erect and cloſer.

It is pretty generally the practice in moſt parts of the kingdom to cut the rye and wheat crops with the ſickle or reaping-hook, a tool which would appear to have been employed for the purpoſe from the moſt early periods of the art of huſbandry. But, in ſome caſes, this tool is employed in a toothed ſtate, while in others it has ſimply a cutting edge. The work is commonly done equally well whichever is made uſe of for the purpoſe. The buſineſs of reaping is performed differently, in reſpect to height and other circumſtances, according as the cuſtom of the diſtrict may prevail. It is uſual, in ſome of the midland counties, and in many of thoſe on the ſouth-eaſt coaſt, to cut the wheat crops at the height of twelve or fifteen, and ſometimes eighteen, inches from the ground; the handfuls, as they are reaped, being laid on bands formed from ſome of the reeds of the crop twiſted or knotted together near to the ear part. Theſe different parcels being bound up into what are termed ſheaves, are either ſuffered to lie upon the ſtubble for a few days previouſly to their being carried, or they are ſet up on their bottoms in double rows, the head of the one ſheaf inclining againſt that of the other oppoſite to it, ſo as to form a ſort of irregular triangle if the baſe be included. But in ſome other caſes the ſheaves are ſet up into a kind of ſtouk without being hooded.

In moſt of theſe caſes, as ſoon as the crop is carted off the land, the ſtubble is mown by means of a ſcythe, and, after being raked into large heaps, is conveyed away to the farmyard, where it is uſed, either for thatching buildings, corn and hay ricks, or as litter for the ſtock.

However, in the north and weſt of this country, and in every part of Scotland where wheat and rye are grown, the crops are reaped as cloſe to the ſurface of the ground as can be conveniently done; and the ſheaves, after being bound up, are ſet into ſhocks, which are provincially termed *ſtouks*, conſiſting of a double row of five ſheaves, or ſometimes ſix, over which, in moſt places, two ſheaves are put in ſuch a way as to completely cover and protect the others in their upper parts. Theſe have the title of *hood* or *cap-ſheaves*, which, when properly placed, have an extremely good effect in preventing even very heavy rains from penetrating and injuring the grain below in any very material degree. It is the cuſtom in ſome places, as ſoon as the hood-ſheaves have been put on the ſtouk, with their root ends uppermoſt, to have their heads ſpread carefully over the top of the ſtouk; as, by the ears being thus reclined, they are in a great meaſure free from injury themſelves, and at the ſame time guard the ſtouks they cover from almoſt any rain that can fall; and, with the view of more effectually preſerving theſe hood-ſheaves in the ſituations in which they have been put, a parcel of ſtraws, the uſual thickneſs of a band, is taken from each ſide below the band of one of the ſheaves, which, together, form a ſort of ropes, that, being conveyed round the other ſheaf, binds them faſt to each other, and of courſe preſerves them both in their due ſituations.

Some, however, conſider this practice of hooding or covering the tops of the ſtouks, as greatly retarding the completion of the work of harveſting, let the nature of the climate be what it may, as the crops in ſuch caſes cannot be ſo quickly ready for being ſecured in the houſe, or built into ſtacks, as when it is fully expoſed to the influence of the atmoſphere. It is conſequently ſuppoſed that the propriety of employing this precaution againſt the effects of bad weather muſt depend in a great degree upon the period at which the crop is reaped, the ſtate of the weather at the time, and the general nature of the climate in the particular ſituation or place. In every one of theſe there is often ſo great and almoſt regular a difference, that the means which the cautious farmer may find it prudent to make uſe of in ſome ſituations, will in others be, if not improper, at leaſt much leſs neceſſary. It is aſked to what, except the circumſtance of the harveſt commencing at earlier periods, and that of the weather continuing more uniformly favourable, it is owing, that the farmers in the ſouthern parts of this country never hood or cover their wheat crops in ſheaf, while that precaution is never overlooked or omitted in the northern parts of the iſland? If this variation in the practice be not accounted for on the above grounds, it is ſuppoſed difficult to explain the cauſes from which it has originated.

By others, both the above practices are ſuppoſed wrong. In fine weather the ears of corn cannot be too much expoſed to the ſun and dews; and even where the grain is thin, a ſlight ſhower is often of great benefit to it. In a rainy ſeaſon they cannot be covered too cloſely; conſequently, in the work of covering the wheat, as in many other branches of rural economy, the farmer muſt be guided by the nature of the ſeaſon, and not by the uſual cuſtom of the diſtrict in which he may reſide.

It is a cuſtom in Oxfordſhire, and ſome other counties, to bind up the wheat into ſheaves, notwithſtanding it may be full of weeds, and ſet them up in three ſheaves together, each ſomewhat ſloping againſt the other, afterwards covering them at their tops with two others opened at their ear ends, which are extended and placed in a downward direction. In this way their wheat crops were formerly let ſtand for three weeks, or longer, in the field, before they were carried, as no wet could, it was imagined, hurt the grain, or cauſe it to grow in the ear. Theſe are now, however, let ſtand a much ſhorter time in the field, being kept more clean from weeds.

In the county of Wilts it was formerly a pretty common practice to form their wheat crops, after being cut into what they term pooks, in which the ſheaves are ſet in a circle with the ears upwards, on which another circle of ſheaves is placed, and ſo on, contracting each round until the pile terminates in a ſort of point, over which a ſheaf, opened in the middle, is turned with the ears downwards, ſomething in the manner of the hackle of a bee-hive, as ears thus turned do not ſo readily grow, though much wet may fall upon them; and, from the bottom of a ſheaf being broader than its top, the upper ones ſhelve over the under ones in the pooks, in the manner of the eaves of a houſe, and the whole is thus kept dry. A pook may in this way be made to contain a load, or even two loads, and render the grain ſecure from wet. But it is not a method that is much had recourſe to at preſent, the grain being left in the field a much ſhorter time than was formerly the caſe. Beſides, it is a mode that takes up too much time.

It is conceived, by a late writer, that the practice of leaving the wheat ſtubble ſo long as to render mowing afterwards neceſſary, is chiefly confined to the more ſouthern and midland counties; and further, that though this be unqueſtionably a remain of the method of harveſting which was introduced by the Romans, it does not ſeem worthy of being imitated at preſent, as being expoſed to numerous difficulties that do not apply to the general and uſual mode of executing the work. It is well known to thoſe converſant with the buſineſs, it is ſuppoſed, that the higher the crop is cut the more heads and ſtems are broken off and dropped; and that whoever will take the trouble of examining a field in which a long ſtubble has been left, will find the loſs of grain extremely great, indeed far more than in caſes where the crops have been reaped pretty cloſe to the ground. Further, the reaping of a crop of wheat, barley, or oats, of the uſual length and thickneſs, is not only better and cleaner, but, at the ſame time, more expeditiouſly performed when cut near to the ſurface of the land. The reaper, by leaning the handful he has reaped gently againſt the ſtanding grain, can go on to cut and keep together with the greateſt facility, a much larger quantity than he can graſp in his hand. But, on the contrary, when the crop is cut twelve or eighteen inches from the ground, he is under the neceſſity of graſping the ſtems before cutting, or they will infallibly drop upon the ſtubble and be loſt. In the former caſe too, an expert reaper will, at every time he ſtoops, reap three or four times the quantity that can be done by the perſon who is obliged to lay hold of the different ſtems; and if to this be added the loſs of grain and of ſtraw, with the unavoidable expence of mowing, raking, carting, and ſtacking the ſtubble, it will, it is ſuppoſed, be difficult, perhaps, for the moſt zealous advocates for this method of harveſting, if it be ſuperior to the other, to diſplay in what this ſuperiority is to be found.

In the report of the county of Perth in Scotland, where cloſe reaping is much practiſed, it is ſtated that low ſhearing produces additional provender for live ſtock; and where the whole of the ſtraw is not required for uſe as food, the cattle will reject the coarſer part, which may ſerve as litter, and being trodden under their feet, will greatly augment the quantity of manure. If a long ſtubble were to be ploughed into the ſoil before winter, it might be of ſervice; but when it has been bleached by the rain and wind, and corroded with the action of froſt, the whole of its juices, and all its manuring virtues, are in a great meaſure loſt and deſtroyed. It is ſuggeſted, that this practice without doubt originated in the idea, that ſeems in former times to have been entertained, that in place of building the crops of wheat in ſtacks, as is at preſent the uſual method of proceeding in other parts of the iſland, it was indiſpenſably requiſite to ſecure them in the barns. The force of prejudice, and the diſlike of innovation of every deſcription may, it is ſuppoſed, have had the tendency, of not only continuing it ſo long, but of contributing to its general eſtabliſhment. (See REAPING.)

In almoſt the whole of the ſouthern parts of this country, the crops of both oats and barley, as well as of peas and beans, are mown by means of a ſtiff ſort of ſcythe, and either repeatedly turned over in the ſwaths, or formed into ſmall cocks, in which ſtates they continue until they are ready for being conveyed to the barns or ſtack-yards. As ſoon as they are in this condition, the carts or waggons are ſet to work, and the whole of the hands that can be ſpared employed in raking the ground after them. In ſhort, the buſineſs is managed pretty nearly in the ſame manner as that in which hay making is performed. The mowing and harveſting grain in ſwath or in cocks, if practices, that can in any climate or ſituation be admitted as beneficial, can only, it is imagined, be conſidered ſo where the harveſts are early, and where the climate is extremely mild, favourable, and ſteady. This being the caſe, it is not probable that ſuch methods can ever become generally eſtabliſhed in this country. For it is believed, that the benefits derived from harveſting the above different ſorts of crops in the ſheaf are extremely numerous, in compariſon to thoſe of the practices that have been juſt noticed.

Indeed, the writer of the Rural Economy of Yorkſhire, appears juſtly ſenſible of their ſuperiority, though much in the habit of harveſting grain in the ſwath, and ſtates the comparative advantages of the different methods to be greatly in favour of the ſheaf method, for all theſe ſorts of grain. The waſte throughout is much leſs; the corn is at once got out of the way of the weather; the labour of carrying, houſing, or ſtacking is infinitely leſſened; much barn room is ſaved, the labour of threſhing is leſs; the ſtraw, where the harveſt proves wet, makes much better fodder; and, under the whole of the circumſtances, the grain preſerves its colour in the ſheaf far better than in the ſwath. And after having ſtated the ſeeming inconveniency of harveſting grain in the ſheaf to principally conſiſt in the increaſe of labour at the outſet, it is concluded that, upon the whole, the quantity of labour performed by men is diminiſhed, not increaſed, by the practice of harveſting in the ſheaf. When to this is added the eaſe and expedition in the work of carrying; which is the moſt important buſineſs of harveſt, and that which requires the greateſt diſpatch, it may be fairly concluded, it is ſuppoſed, that by harveſting in the ſheaf, the labour, the anxiety, and the riſk of harveſt are leſſened, and at the ſame time the quantity, as well as the value of the produce, is augmented. And farther, it is ſuggeſted by another writer, that if the above author had been perfectly acquainted with the great benefits derived from the uſe of threſhing machines, and been alſo aware of the almoſt impoſſibility of threſhing clean by ſuch machinery, unleſs where the grain is ſpread out evenly upon the board, and taken in regularly by the feeders, he would have ſtated this as one principal reaſon why crops of the oat and barley kinds ſhould be harveſted in the ſheaf method.

In different parts of Yorkſhire, and ſome other neighbouring diſtricts, it is an uſual cuſtom to mow the crops of oats, barley, beans, and other ſimilar kinds with the ſcythe, and then to bind them up into ſheaves, ſetting them up afterwards into ſtacks in the manner that has been already noticed, in ſpeaking of wheat crops. Where it is the intention to harveſt grain in the ſwath, or cock method, the uſual mode is to mow in an outward direction, or from the ſtanding corn, as is practiſed with graſs; but when it is deſigned, that it ſhould be bound up into ſheaves, it ſhould be mown inwards, or towards the ſtanding grain. By this means, and that of fixing what is termed a cradle over the ſcythe, or bows made of willow ſhoots on the heel, or lower end of the ſcythe ſhaft, the corn is made to fall eaſy and regularly off the ſcythe, and to reſt againſt the ſtanding grain in an inclining manner. A woman and a boy generally attend each mower. The boy is, for the moſt part, engaged in making bands, but in ſome caſes alſo in binding the ſheaves. The woman, with a long toothed wooden or iron toothed rake, having a ſhort ſhaft, or handle, gathers and collects the grain, after being mown, into portions about the ſize of a ſheaf, and, with equal dexterity and quickneſs, lays it regularly into the band, without ever ſtooping or touching it with the hands. However, in ſome ſituations this ſort of work is more conveniently accompliſhed by means of a kind of fork, which is formed with two

prongs

prongs below, ſomewhat in the manner of the common hay fork, to which are fixed at the upper part two upright prongs, by which the grain is removed from the ſwath, and collected into ſheaves, the lower prongs lifting it up, while thoſe on the upper ſide prevent its falling backwards, and determine the quantity which is ſufficient for the ſheaf. By this ſimple contrivance, it is ſuppoſed, that the grain may be gathered more regularly, and much more expeditiouſly into the ſheaf, than by the labour of the hand, as uſually practiſed.

It is uſual, as ſoon as the mower has reached the end of the field, in ſome places, for him to begin to bind and ſet the ſheaves into ſtouks, which he goes on doing in the whole of his returning courſe towards the end of the ſwath, where he began with the ſcythe. In this caſe the woman is, in the mean time, employed in raking the ſtubble, which, on lands that have been properly harrowed and rolled, is eaſily done, and ſo effectually, that ſcarcely a ſtem is loſt. In the work of performing theſe different operations, there are, however, ſeveral variations to be met with in the practice of different places.

It is ſuggeſted, that this plan of harveſting oats, barley, and ſome other crops, may, for numerous reaſons, be conſidered ſuperior to that of reaping, and conſequently, deſerve more than ordinary attention from thoſe who are not well acquainted with the practice, and who are not ſo much attached to ancient cuſtoms, as to diſregard every means of improvement, becauſe they are not generally adopted in the places where they are ſituated. The great ſcarcity of labourers, and the rapid advances in the rates of harveſt wages, are felt in the moſt ſevere manner, and complained of with earneſtneſs; of courſe every mode, by which the number can with propriety be reduced, and by which various other deſcriptions of labourers, as women, boys, girls, &c. can be ſubſtituted with propriety in the harveſt-field, muſt have the tendency of obviating the loſs, inconvenience, and additional expence, to which the farmer is ſubjected, in conſequence of the deficiency in the number of hands, which is too frequently experienced at ſuch buſy ſeaſons. It is contended, indeed, that without the aid which is derived during the harveſt months from the poor neglected peaſantry of Wales and the Highlands of Scotland, the grain crops in many of the more fertile parts of the iſland could not, by the preſent generally practiſed mode of harveſting, be cut and gathered in, without taking ſuch a number of hands from the various manufactures of the country, as would be inconvenient, and at ſuch rates of wages as would almoſt amount to the prohibition of the cultivation of grain crops.

It is ſtated, on the ground of attentive examination, that the mode of harveſting which is practiſed in Yorkſhire, is preferable, in every point of view, as a general method, to any other that has been adopted in the kingdom. And that it ought to be introduced into the northern and weſtern parts of this country as well as every part of Scotland, eſpecially wherever improved cultivation, and various extenſive manufactories have been eſtabliſhed.

Notwithſtanding oat, barley, bean, and ſome other ſimilar kinds of crops, are however occaſionally mown with the ſcythe, they are, as has been already ſeen in the greateſt portion of the iſland, cut by the ſickle; and in the ſouthern parts of it moſtly by women, while in Scotland there is generally a pretty equal mixture of men and women employed in the buſineſs. There, in general, the ploughmen are no farther engaged in the harveſt work, than merely in bringing home the crops to the ſtack yards. In ſome particular diſtricts however, eſpecially towards the northern extremities, every operation of the plough and harrow, &c. is ſuſpended, and the ploughmen are made to bear a ſhare in the labours of the harveſt field. There is nothing particular in the manner of performing harveſt work in this part of the iſland; the grain being chiefly reaped low with the ſickle, bound up into ſheaves, and ſet in ſtouks.

In regard to the rates of harveſting, they are extremely various, according to particular circumſtances, in the different parts of the kingdom, and of courſe not capable of being aſcertained with any uſeful accuracy. But it may be noticed that a man, accuſtomed to the uſe of the ſcythe, is capable of performing his work over as much ground as four reapers. The expence in the ſcythe method is of courſe much leſs, the number of hands much reduced; and other deſcriptions of them than thoſe at preſent employed, rendered capable of being uſeful, conſequently leſs difficulty experienced in providing a ſufficient number.

Beſides, the work is executed in an equally complete manner, and with far more expedition; while at the ſame time the quantity of the neceſſary article ſtraw is greatly augmented.

It may be remarked that greater expedition in harveſting is requiſite in proportion to the heat of the ſeaſon; as grain that is haſtily ripened, ſcorched up by the action of the ſun, and full in the ear, ſpeedily takes on a ſtain, is quickly injured by moiſture, and eaſily ſheds by every blaſt of wind. It is conſequently adviſable to loſe no time in ſuch caſes, but immediately to employ a greater number of perſons as reapers, as more cannot be required than that the corn be well ripened, and good in the colour, to produce which the leſs it then lies abroad, either in the grip or ſheaf, the better. Reaping high where the bottom is weedy may greatly aſſiſt in this view. And for hilly diſtricts it has been ſuggeſted by an old writer, that grain can never be better houſed, when it is perfectly ripe, hard, and has no mixture of weedy matter, than by gripping it and carting as faſt as it is cut down, as the dampneſs cauſed by its lying upon the ground during the night is not eaſily expelled. With wheat it is moſt generally adviſable to turn ſuch grips as are left out, as early as poſſible after they have been formed, in order that they may ſpeedily become dry. In this way they are capable of being preſerved longer from ſprouting in the ear in caſe there ſhould be rain. But when dripping weather or driving miſts enſue, and continue for any length of time after ſuch grips have been loaded with wet, it is impoſſible for the art of man to prevent their growing. Independent of other accidents, even the bare weight of the ears will ſink the grips to the ground, though they may have been laid in the lighteſt manner, by which they muſt be injured if ſuffered to remain long out in bad ſeaſons. And on ſomething of this principle it is that the farmers in the counties of Leiceſter and Northampton, eſpecially where the lands are rich, deep, and flat in their ſituation with much incloſure, leave a very high wheat ſtubble, on which the grips of corn are held up and ſupported quite hollow and free from the ground, and of courſe are more eaſily dried by the ſun and the wind; for it may be remarked that on rich ſoils the grips will grow more readily after they have taken wet, when on the naked ground, than in the contrary circumſtances, particularly in hilly ſituations.

In all caſes the more forward the harveſt ſeaſon is, and the more warm the weather, and the longer the grain may remain with ſafety in the field, whether it be in grips or ſheaves, as ſuch expoſure to the atmoſphere after it is cut not only mellows it, but makes it threſh better and look finer, as has been already ſuggeſted. Hence, when the wheat harveſt takes place by the middle or before the latter end of July, which is ſometimes the caſe, there is little danger

danger in letting the grain lie abroad for three or four days, or even a week, if it be not over ripe when cut, though a rainy day or two ſhould intervene, as at ſuch a period of the year the ſun is generally ſo hot, the days ſo long, and the dews commonly ſo trifling, that the corn ſoon dries even after a heavy ſhower; while in the middle, and ſtill more towards the end of the following month, the rains commonly begin, the dews are more powerful, and the ſun's drying power ſo greatly leſſened, that if wet weather takes place then, the grain will be much more liable to grow and be injured.

It has been ſuggeſted, by way of caution, by an old writer, that it is material in hilly diſtricts not to bind the grips of wheat into ſheaves, at too early a period in the courſe of the day, as in ſuch ſituations they have taken ſuch a damp by having lain upon the ſurface of the ground, that though the ſtraw and chaffy ears may appear dry as ſoon as the dew is firſt diſſipated, and the ſun has ſhone a few hours upon them, there will ſtill remain an inward dampneſs in the ſtraw and grain, which will be injurious in the ſtack or mow. The afternoon ſhould of courſe be choſen for the purpoſe of gripping and binding the grain into ſheaves in ſuch places, the work being finiſhed before the approach of night. It is beſt, however, to lay the bands in the morning, as they will then twiſt better and be leſs brittle than after the ſun has ſhone ſome time on the corn. They ſhould always be made ſtrong and well twiſted together, in order that they may contain the corn without giving way. But though the modes adviſed above may be practiſed with propriety in ſome inſtances, and for ſome kinds of corn, they ſhould not be much employed for wheat crops, as it is found that the leſs they are expoſed to wet and heat the better. On this principle, the practice of covering the ſhocks of wheat with cloths and mats, is in uſe in ſome places in the county of Kent, as between Sandwich and Dover. The mats are found the beſt and are the moſt commonly employed. By this means it is ſuppoſed that the ſample of the grain is ſo much improved, that the bakers at Dover give a decided preference to ſuch as is treated in this manner. The expence of mats for this uſe is about ſeven-pence each, which, if properly taken care of, will laſt many years.

In regard to the buſineſs of tying up the ſheaves, it may be noticed that it is a work that is not always ſufficiently attended to. By way of diſpatch the reapers are ſometimes apt to bind them too near the ear ends, the conſequences of which are that they ſlip through the bands, do not hold together while they are thrown into the carts in loading, and moſt generally fall through the bands before they are threſhed. When ſlight rain is foreſeen at harveſt time, it is the beſt way to bind up the grips of corn as faſt as they are formed into ſheaves, as ſmall ſhowers will wet them ſo much as to prevent its being done with propriety. But it is better never to cut grain at all under the circumſtances of wet, as it is always a bad practice, where it can be avoided. When the harveſts are wet it is the beſt to have the ſheaves ſmall, as from their being thin at the tops, and falling cloſe, the rain does not ſo readily ſink down into the middle of them, and thence get through to the bands, which it is very liable to do in large ſheaves that lie broad and take up more room. The ſmall ſized ſheave is likewiſe the moſt proper, where there is much weedy matter intermixed with the grain, which however ought never to be the caſe, as the air, ſun, and wind, have greater power in drying than under the contrary circumſtances. And the writer of "Minutes of Agriculture" adviſes, that the ſheaves ſhould only be tied in a looſe manner, and neither too large or too ſmall; they muſt not, however, be left too looſe, as in that caſe they will be in danger of ſlipping through the bands wholly, beſides their being difficult to load and worſe to ſtack. It is likewiſe ſuggeſted, that they be ſet up in ſuch a way as only to juſt touch each other at the butts and ears, a ſpace of a foot and a half being left between each ſheaf, at the ſpot where they are bound, the ears of the bands being conſtantly turned inwards. In general, it is aſſerted, the ſmall looſe-tied ſheaves will dry ſoon, while the large tight-tied ones of the ſame ſhock will grow; and that the ears of the bands are the firſt parts that begin to grow. Further, that thoſe ſhocks which ſtand free and open, are much ſofter than thoſe of which the ſheaves ſtand together in a cloſe huddled manner, through which neither ſun nor air can penetrate. It is ſtill farther recommended that inſtead of tying the bands near the butts, as is uſual, they ſhould be tied looſely about the ſame diſtances from the tops, ſpreading out the butts, and ſetting up the ſheaves in the ſugar loaf form ſingly, leaving the inſides totally hollow. By this means they are enabled to dry quickly; when by ſhifting the bands back again the ſucceeding day to the common binding places, and opening the ears a little, they become ſpeedily in a ſtate for carrying. This, however, is a mode that cauſes conſiderable additional trouble.

In places where the harveſts are late and rainy, the preſervation of grain crops is moſtly arduous and difficult. Conſequently, other methods beſides thoſe commonly employed, and which have been already detailed, are had recourſe to occaſionally, ſuch as what are termed gaiting and hutting. Theſe modes are, however, only practiſed in ſuch caſes as where, from the precarious ſtate of the weather, the crops would be in great danger of being ſpoiled, without ſome unuſual exertion. Theſe methods are made uſe of in ſeveral of the more northern counties of England, as well as in ſome parts more towards the north in Scotland, and do not appear bad methods of harveſting grain crops in late unfavourable ſeaſons. The work is executed in this manner: the ſheaf, inſtead of being bound tight towards the butt-end, as is commonly the caſe, is tied ſlackly, and the band moved up until it reach ſome of the ears. The binder then ſets the ſheaf in a rather forcible manner on its bottom, ſo as to give it a ſort of baſe to ſtand upon. And where the corn is gaited by thoſe who are experienced in the buſineſs, the bands are conſtantly puſhed down the middle of the ſheaves, after they have been ſet on end, and the bottoms ſpread out, the middles being left hollow, and care taken to form ſmall openings towards the ſouth, by which contrivance the air as well as the ſun have the greateſt poſſible influence in preſerving the crops, and rendering them fit for being carried and ſtacked up. In caſes where grain crops are cut in a wet ſtate, as not unfrequently happens towards the end of a late harveſt, this is in all probability the beſt plan that can poſſibly be deviſed for preventing the threatening miſchief. The mode of hutting in the field, in order to ſave grain in bad harveſt ſeaſons, is alſo a practice often had recourſe to with ſucceſs, in the north-weſtern parts of Scotland, eſpecially when put up in a tolerable ſtate of dryneſs. The huts are made upon the field immediately after the crops are reaped, and bound up into ſheaves. They are, in general, only formed of ſuch a ſize, that a man is capable of building them in ſtanding upon the ground; and conſiſt in common of from twelve to twenty ſtooks, in proportion as the ſtraw is more or leſs bulky. If theſe huts be properly formed, and a ſheaf or two carefully ſpread over their tops, ſomewhat in the umbrella method, ſcarcely any weather, however bad, or of whatever continuance, will affect the grain in any material degree.

Upon taking one of theſe huts down, after it had ſtood

five or ſix weeks, or probably longer, under the moſt ſevere rains that had happened during any harveſt for a great length of time, it was found that, except a few of the top-ſheaves, the whole was in a ſurprizing ſtate of preſervation. And this was the more remarkable, as the crops in ſome of the adjacent fields where this precaution had been neglected, though carefully ſtooked and hooded, were grown and matted together in ſuch a way that every ſtook formed an united maſs, not only of vegetable, but vegetating matters. In places where the harveſts occur at a late period; where the weather is unfavourable, and where the approach of winter is apprehended, the practice of hutting grain in the field may be ſafely adviſed as a beneficial plan. And where the weather continues long rainy, and there is reaſon to apprehend the ſpringing of the grain in the ear, or that heavy falls of ſnow may take place, as occaſionally happen, the moſt proper method is to reap and gait as expeditiouſly as poſſible.

In regard to houſing and ſtacking of grain products, it is the cuſtom of ſeveral of the northern, midland, and ſouth-weſtern parts of the kingdom, to have the barns of a large ſize, and to houſe the whole, or at leaſt as much as poſſible of the wheat crops directly from the field. But in moſt other parts the wheat, as well as other ſorts of crops, are built into ſtacks in a yard for the purpoſe, as near as poſſible to the barns, into which it is conveyed only as it may be found convenient for being threſhed out. And crops of the oat, bean, barley, and pea kinds are almoſt every where put into ſtacks in the yards appropriated for them, being raiſed in different forms, according to the cuſtom of the particular ſituations. With reſpect to houſing the crops from the field, it can only be practiſed with propriety when they are perfectly clean and dry; and is of courſe a method which, if it were adopted to any extent in thoſe diſtricts where the climate is particularly precarious and unfavourable, could not fail to be attended with bad effects. The building of the crops into ſtacks is without doubt the beſt and moſt convenient method of preſerving the grain as well as the ſtraw; but in the view of preventing loſs by vermin, and the bottoms of the ſtacks from injury and muſtineſs by their coming in contact with the moiſt ground, they ſhould always be built on a frame-work placed upon pillars of ſtone or wood. Where this is the caſe, and the caps of the pillars are of ſuch dimenſions and ſo placed as to prevent the entrance of rats and mice into the ricks, theſe being well built and properly thatched, the grain will keep in excellent condition for a very great length of time.

With regard to the buſineſs of carrying the crops from the fields, notwithſtanding there is much diverſity in the ſize, ſhape, and conſtruction of the carts and waggons that are employed for the purpoſe, as well as in the ſtrength of the teams by which they are drawn, there is but little variation in the general mode of conducting the work. The grain crops, in whatever mode they may be harveſted, are put upon the carriages by perſons ſtationed in the fields expreſsly for the purpoſe, and on being drawn to the rick-yard are forked by the carters to the ſtacks.

It has been lately ſuggeſted, that where the number of teams are ſufficient, in carting the wheat crops, three waggons ſhould be employed ſomewhat in this manner, one of them loading in the field, one unloading, and one upon the road going in different directions. For this, five or ſix horſes are quite ſufficient, with two men to pitch, the ſame number to load, one to drive, and two to manage the buſineſs of unloading; in the whole ſeven, which make great diſpatch. But the uſe of ſingle-horſe carts is far ſuperior, whatever the number of horſes employed in the work may be. Let each of theſe be in a well formed cart, and a great deal more ground will be cleared than can be effected by the waggons.

In inſtances where the grain crops are harveſted from the ſwaths, a number of perſons are employed in the buſineſs of ſtacking, an operation which is conducted in the ſame way as for hay; but where the grain is bound up into ſheaves, one perſon only is neceſſary in forming the ſtack, unleſs where it is of more than ordinary dimenſions; in which caſe the aſſiſtance of a boy is commonly required, who receives the ſheaves from the carter, and hands them to the man who is employed in building the ſtack. In executing this kind of work it is neceſſary to attend to different circumſtances, ſuch as the ſhape and the manner of building, trimming, and thatching, as upon each of theſe being properly performed, much benefit depends in the preſervation of the contents. See STACKING *and* THATCHING *of Grain*.

Where it is difficult to provide a ſufficient number of reapers, and where the farms are very large, as well as the crops various, it is obvious that a much longer time is requiſite to complete the buſineſs of harveſt, than under the contrary circumſtances. The experience of bad harveſts ought to ſuggeſt the propriety and advantage of ſowing at an earlier period, and of exerting every poſſible means, at the critical ſeaſon of harveſt, to collect and get in as quickly as can be ſafely done the grain crops, and not by any cauſe to neglect the opportunity of gathering a ſmall portion, becauſe a great deal is not ready. And in no caſe to be engaged in reaping, when the teams ought to be employed in loading and ſecuring the grain, nor for one moment to loſe ſight of the great object which is to crown the labours of the year. Tedious and unfavourable harveſts are ſerious evils, and the loſſes, inconveniences, and anxieties which they produce, are only to be alleviated by the greateſt attention, care, and exertion during ſuch buſy periods.

HARVEY, WILLIAM, in *Biography*, a celebrated phyſician and anatomiſt, and author of one of the moſt important diſcoveries ever made in phyſiology, was born at Folkſtone, in Kent, on the 1ſt of April 1578. He received the rudiments of his education at a grammar-ſchool in Canterbury, and in 1593 was admitted a penſioner of Gonville and Caius college, Cambridge. At the age of 19 he went abroad for profeſſional improvement, and, after viſiting France and Germany, fixed himſelf at Padua, at that time the moſt celebrated medical ſchool in Europe. Here he took his doctor's degree in 1602; and, returning to England, repeated his graduation at Cambridge, and ſettled in the practice of his profeſſion in London. He became a fellow of the College of Phyſicians in 1603, and a ſhort time afterwards was appointed phyſician to St. Bartholomew's hoſpital. In 1615 he was nominated lecturer on anatomy and ſurgery to the college, an appointment which was probably the more immediate cauſe of the publication of his grand diſcovery of the circulation of the blood. The date of this promulgation is not abſolutely aſcertained: it is commonly ſaid that he firſt diſcloſed his opinion on the ſubject in the year 1619; but the index of his MS. "De Anatomia univerſa," containing the propoſitions on which the doctrine is founded, refers them to April, 1616. Yet with a patience and caution, peculiarly characteriſtic of the ſound philoſopher, he withheld his opinions from the world, until reiterated experiment had amply confirmed his doctrine, and had enabled him to demonſtrate it in detail, and to adduce every proof of its truth of which the ſubject is capable. It is unneceſſary here to enter into the controverſy reſpecting the previous knowledge of the ſubject by the ancients, for which ſome have contended, or to ſtate the ſteps by which ſome of Harvey's

Harvey's predeceſſors had paved the way for his diſcovery, or the abſurdities to which the bigotry and prejudices of his contemporaries carried them, in their oppoſition to his doctrine; theſe points have been amply elucidated in a former article. (See CIRCULATION, *Diſcovery of.*) As this was a diſpute in which no particular intereſts oppoſed the final reception of truth, Harvey had the ſatisfaction of living to ſee his doctrine fully eſtabliſhed, and all reputable oppoſition withdrawn. It is ſomewhat mortifying, however, to find that, ſo far from advancing his reputation and ſucceſs as a candidate for practice, this unrivalled diſplay of ſagacity, induſtry, and knowledge ſeems to have had a contrary effect; for he never appears to have occupied the higheſt rank as a medical practitioner. "Perhaps," ſays Dr. Aikin, "his experimental reſearches took him out of the common road to popular eminence; and they ſeem to have expoſed him to the prejudice ſo commonly prevailing againſt an innovator; for we find him complaining to a friend, that his practice conſiderably declined after the publication of his diſcovery."

The character which Harvey had obtained, recommended him however to the notice of the court; he received conſiderable favours from James I., and ſtill greater regard from Charles I., who uſed to attend occaſionally, with ſome of his courtiers, to witneſs his diſſections and experiments. The intereſt which his majeſty took in the ſucceſs of his anatomical reſearches, was of ſingular ſervice to him in his inquiries relative to generation, as the king's favourite diverſion of ſtag-hunting furniſhed him with the opportunity of diſſecting numerous females of that ſpecies in different ſtages of pregnancy. Harvey had held the appointment of phyſician extraordinary to James, and was now made phyſician in ordinary to Charles; who alſo evinced his regard by appointing him to accompany the young duke of Lennox in his travels. It is probable too, that he accompanied the king himſelf, in his journey to Scotland in 1633; for he has given from his own view a moſt elegant and lively deſcription of that great reſort of ſea-fowl, the Baſs-iſland. At the breaking out of the civil war, he remained attached both by office and affection to the royal perſon, and after the battle of Edge-hill, went, with the reſt of the houſehold, to Oxford, where he received other marks of favour. During theſe troubles, his houſe in London was pillaged, and his papers, containing obſervations in anatomy and natural hiſtory, the reſult of the labour of many years, particularly relating to the generation of inſects, were deſtroyed. Of this irretrievable loſs he has complained in his works in terms which, though mild and modeſt, ſhew how ſeverely he felt it. (See Exercitat. lxviii. ad finem.) Upon the ſurrender of Oxford to the parliament, he retired to a private mode of life in London, at Lambeth, or at his brother's houſe at Richmond.

He had publiſhed his firſt work on the circulation in the year 1728, under the title of "Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus," at Francfort, which place, by its great fairs, afforded the beſt means of circulating his opinions throughout Europe. The oppoſition which was excited againſt the new doctrine, had alſo cauſed him to publiſh two other "Exercitations," in refutation of his opponents. In 1651, when Harvey was in the 73d year of his age, he was prevailed upon by Dr. George Ent, who viſited him in his retirement, to publiſh, or rather to ſuffer him to publiſh, his other great work, the "Exercitationes de generatione animalium," which had employed a large portion of his time and attention. Theſe exercitations are ſeventy in number, and the general inference from the whole of the facts is the univerſal prevalence of oval generation. This work has undergone numerous editions on the continent.

In the following year, 1652, Harvey had the ſatisfaction of ſeeing his merits acknowledged by his brethren in an unuſual and moſt honourable manner; by a vote of the college, his buſt in marble was placed in their hall, with a ſuitable inſcription recording his diſcoveries. He returned this compliment, by preſenting to the college, at a ſplendid entertainment to which he invited the members, an elegantly furniſhed convocation room, and a muſeum filled with choice books and chirurgical inſtruments, which he had built, at his own expence, in their garden. On the reſignation of Dr. Prujean, in 1654, Harvey was unanimouſly nominated to the preſidency, but he declined the offer on account of his age and infirmities. He ſtill, however, frequented the meetings of the college; and his attachment to that body was ſhewn more conſpicuouſly in 1656, when, at the firſt anniverſary feaſt inſtituted by himſelf, he gave up his paternal eſtate of fifty-ſix pounds *per annum* in perpetuity, for their uſe. The particular purpoſes of this donation were, the inſtitution of an annual feaſt, at which a Latin oration ſhould be ſpoken in commemoration of the benefactors of the college, a gratuity for the orator, and a proviſion for the keeper of his library and muſeum. His old age was afflicted with infirmities, eſpecially with moſt excruciating attacks of the gout; but he lived to complete his 80th year, and expired on the 3d of June 1658, in great tranquillity and ſelf-poſſeſſion.

The private character of this great man appears to have been in every reſpect worthy of his public reputation. Cheerful, candid, and upright, he lived on terms of great harmony with his friends and brethren, and exhibited no ſpirit of rivalry or hoſtility in his career. He ſpoke modeſtly of his own merits, and generally treated his controverſial antagoniſts with temperate and civil language, often very different from their own. He wrote in a remarkably perſpicuous Latin ſtyle, which is flowing and even eloquent where the ſubject allows of ornament. The College of Phyſicians very properly honoured his memory by a ſplendid edition of all his works in quarto, 1766, to which a Latin life of the author was prefixed, elegantly written by Dr. Laufence. See Gen. Biog. Aikin's Biog. Mem. of Med. Eloy. Dict. Hiſt.

HARVEY, GIDEON, alſo a phyſician, was born in Surrey. He acquired the Greek and Latin languages in the Low Countries, and was admitted of Exeter college, Oxford, in May 1655. He afterwards went to Leyden, where he ſtudied medicine, ſurgery, and pharmacy, and thence to Paris, and ultimately took his doctor's degree in ſome French univerſity. He returned to Holland, where he was admitted fellow of the college of phyſicians at the Hague, and alſo made phyſician to Charles II. in his exile. After his return to London, he was ſent to Flanders, in July 1659, in the office of firſt phyſician to the forces, after which duty he travelled through Germany to Italy, ſpending a conſiderable time at each of the principal ſeats of learning, and then returned through Switzerland and Holland to England. On the arrival of William III., he was appointed phyſician to the Tower. He died about the year 1700.

Gideon Harvey publiſhed ſeveral works after the termination of his travels, which are nearly forgotten. Unlike his predeceſſor of the ſame name, whoſe modeſty equalled his knowledge, and who never proceeded a ſtep without fact and experiment, Gideon Harvey was a vain and hypothetical prater throughout. Under the pretence of reforming the art of medicine, he attacked the characters of the moſt eminent phyſicians of the time, combining the moſt inſulting ſar-

caſms, with many glaring falſhoods and abſurdities; and although, in the general war which he waged, he juſtly fell upon many abuſes which then prevailed in the profeſſion, yet he often committed great errors of judgment; and in the attempt to diſplay his wit, exhibited but too many proofs of malignancy in his diſpoſition. His principal work, part of which was publiſhed in 1683, and part in 1686, was entitled "The Conclave of Phyſicians, detecting their Intrigues, Frauds, and Plots againſt the Patients, &c." He alſo publiſhed a treatiſe on ſyphilis, under the title of "Little Venus unmaſked," Lond. 1668. "Morbus Anglicus, or the Anatomy of Conſumption, &c." 1673. "De Febribus Tractatus Theoreticus et Practicus, præcipue quo Praxim curandarum Febrium continuarum modernam eſſe lethiferam et barbaram, abunde pateſit," 1672. "Diſeaſe of London, or a new Diſcovery of the Scurvy," 1675. "The family Phyſician, and the houſe Apothecary," 1678. "Caſus medico-chirurgicus," 1678. "New Diſcourſe of Small Pox and Malignant Fevers, &c." 1685. "Art of curing Diſeaſes by Expectation," 1689. "The Vanities of Philoſophy and Phyſic," 1700. See Eloy. Dict. Hiſt. Biograph. Dictionary.

HARVEY's *Iſland*, in *Geography*, an iſland in the Southern Pacific ocean, compoſed of three or four ſmall iſlands, united together by rocks, covered by the ſea; the whole about 20 miles in circumference; diſcovered by Captain Cook in 1773. S. lat. 19° 18'. W. long. 158° 48'.

HARVEY's *Point*, a cape on the coaſt of North Carolina, in Albemarle ſound. N. lat. 36° 6'. W. long. 76° 34'.

HARUN, a town of Perſia, in Segeſtan; 15 miles S.W. of Zareng.

HARUSPEX, or ARUSPEX, in *Antiquity*, a ſort of prieſt, or diviner, who inſpected and conſidered the entrails of beaſts, particularly thoſe of victims, to find ſigns or indications of ſomething he wanted to know. See ARUSPICES.

Cicero, De Divinat. lib. ii. explains the difference between aruſpex and haruſpex.

HARUTSCH, in *Geography*, a mountainous diſtrict of Africa, in the road from Augela to Temiſſa, divided into black and white Harutſch. The mountainous deſart, called black Harutſch, Harutch-el-Aſſuat ("Mons ater" of Pliny) is repreſented by Mr. Horneman, as the moſt remarkable region that fell under his obſervation during his journey to Mourzouk. Its extent was ſtated to him to be ſeven days' journey from N. to S., and five days' journey from E. to W. In his ſubſequent travels from Fezzan to Tripoly he fell in with another branch of the Harutſch, and received information that it extended much farther to the W. At Mourzouk he was told that there were black mountains on the road leading ſouthward to Bornou, on which the temperature was cold, and from which the people of Mourzouk obtain their iron; and theſe mountains he conjectured to be alſo branches of the Harutſch. The rugged, broken, wild, and terrific ſcene which this deſert tract affords, ſuggeſts to the naturaliſt, that the convulſed form and appearance of this mountainous diſtrict are owing to a volcanic irruption at ſome remote period. The general face of the country exhibits continual ranges of hills in various directions, from eight to twelve feet only in height; and between theſe, on perfect flats, and without any gradual aſcent, riſe up inſulated mountains, whoſe ſides are very ſteep from the baſe. The maſs of theſe mountains conſiſts of a ſtony ſubſtance, of various colour and denſity, in ſome parts compact and heavy, and in others having ſmall holes and cavities. Contiguous to the black Harutſch is the white Harutſch, or "Harutſch-el-abiat." This diſtrict is an immenſe plain, interſperſed with iſolated hills, and extending to the mountains that riſe towards Fezzan. The ſtones which cover this plain appear glazed, and this is the caſe with the rocks which occaſionally riſe or project from the level. Among the ſtones are found fragments of large petrified marine animals, but moſtly ſhells cloſed up and iſolated: theſe ſhells, when ſtruck, emit a ſhrill ſound, and the fracture exhibits a vitreous appearance. The low, bare, calcareous hills that border the plain, are compriſed by the Arabs in the Harutſch-el-abiat; but our traveller obſerves that they are of a very different nature. Of all which he ſaw, this range of hills contains the greateſt number of petrifactions; conſiſting of conchs, ſnail-ſhells, fiſh, and other marine ſubſtances. He found heads of fiſh, large and heavy enough as a burden to one perſon; and in the adjacent vallies were numerous ſhells, of the ſame kind with thoſe found in the great plain, and which had the ſame glazed appearance.

HARWICH, a ſea-port, borough, and market town in the pariſh of Dover-court, within the hundred of Tendring and county of Eſſex, England, conſiſted, in the year 1800, of 493 houſes, and contained 2761 inhabitants. The houſes are ſeated on a point of land, which projects into the ſea, and is bounded to the north by the eſtuaries of the rivers Stour and Orwell. In the vicinity of the town are ſome remains of a conſiderable encampment, which it is ſuppoſed was either formed, or occupied, by the Romans, as ſeveral coins, and fragments of a teſſellated pavement, have been diſcovered beneath the ſurface of the ground. The Saxon Chronicle records a battle, which was fought near this port, between the fleet of Alfred, and 16 Daniſh ſhips, in the year 885, when the latter were completely defeated and every veſſel taken. In the time of king Edward II. Harwich was made a borough and market town by charter, dated 1318. Several ſubſequent monarchs confirmed and enlarged this charter, but the preſent corporation, &c. are regulated and governed by a charter from king James I. paſſed in the 12th year of his reign. The town was formerly ſurrounded by fortified walls, which were provided with embattled gate-ways. Here were alſo a caſtle, and various ſmall forts, or block-houſes. The ſea has waſhed away the foundations of the latter, and the former has been levelled to the ground. The parochial chapel here, was founded by Roger Bigod in the thirteenth century. Among ſeveral monuments within it, is one to ſir William Clarke, knight, who was ſecretary at war to kings Charles I. and II. The other public buildings here are a town-hall and gaol, a ſchool-houſe and a cuſtom-houſe. Harwich has a dock-yard provided with ſtore-houſes, launches, and other requiſites for building and fitting out veſſels. Some third-rates and other veſſels of large burden have been built here. The harbour is deep and ſpacious, and the anchorage good. Near the town is a light-houſe for the uſe of mariners in coming in and going out of this harbour. Many ſmacks, belonging to Harwich, are employed in the North-ſea fiſhing: their burden has been calculated at more than 3000 tons, and they give employ to about 500 ſeamen. This is the uſual port, in times of peace, for packets which ſail to Holland, Germany, &c. Hence kings William III. and George I. and George II. viſited this place in their reſpective journies to and from the continent. Her preſent majeſty landed here on her firſt viſit to this kingdom. Harwich has recently become a place of reſort for ſea-bathers, for whoſe accommodation, many improvements have been made in the town. In a cliff ſouth of Harwich, various teeth of large animals, and bones of great ſize have been found. Some writers have conjectured theſe to be the remains of the elephants brought into England by Claudius

Claudius in the year A.D. 43. On a point of land oppoſite to Harwich, but in the county of Suffolk, is a ſtrong fortification called Languard-fort, which was erected to defend this harbour in the time of king James I. About one mile S.W. of Harwich is Dover-court, the church of which was celebrated, in the age of monachiſm, for its miraculous rood, or cruciſix, which was much frequented by pilgrims and religious devotees. Morant's Hiſtory, &c. of Eſſex, 2 vols. folio. Hiſtory of Harwich and Dover-court, 4to.

HARWICH, a poſt-town of America, in Barnſtaple county, Maſſachuſetts, ſituated on Cape Cod, between Yarmouth and Chatham, extending acroſs the cape, which is here about ſix miles broad, and containing 2857 inhabitants; 88 miles S.E. of Boſton.—Alſo, a townſhip in Rutland county, Vermont, watered by Otter creek, and containing 153 inhabitants.—Alſo, a townſhip in the weſtern diſtrict of Upper Canada, having lake Erie on the S. and the river Thames on the N.

HARWINGTON, a poſt-town of Connecticut, in Litchfield county, eight miles E. of Litchfield; containing 1431 inhabitants.

HARWOOD, EDWARD, in *Biography*, was born in the year 1729, and having paſſed with reputation through his grammatical learning, he was entered as ſtudent for the profeſſion of a Diſſenting miniſter, in the academy ſupported by Mr. Coward's funds. Upon quitting this place, he engaged as an aſſiſtant to a boarding ſchool at Peckham, and preached occaſionally for ſome neighbouring miniſters in and out of London. During this period of his life he ſtudied very diligently the Greek and Roman claſſics, to which he was devoted through life. In 1754 he undertook the care of a grammar ſchool at Congleton in Cheſhire, and preached for ſome years, on alternate Sundays, to two ſmall ſocieties in the vicinity of that town. In 1765 he removed to Briſtol, and in about five years he was obliged to quit his ſituation on account of his principles as an Arian and Arminian, terms which, among the ignorant and bigotted, are regarded with as much horror as Atheiſm; for rendering proper homage to the one only true God; and for aſcribing to him the attributes of infinite benevolence, extended to all his creatures in a tract entitled "The melancholy Doctrine of Predeſtination expoſed." Mr. Harwood could ſcarcely walk along the ſtreets of Briſtol without inſult. This is his own account of the matter, but it muſt not be forgotten that he was charged with immoralities that are never endured in a diſſenting miniſter, who depends for his ſupport on the voluntary contributions of his hearers. From one or other, or perhaps from both theſe cauſes he was unable to purſue his profeſſion and left Briſtol. He had, previouſly to this, obtained the degree of doctor of divinity from one of the Scotch univerſities; with this he came to London, and obtained employment as a literary character, and alſo as an inſtructor in the Greek and Latin claſſics. He died miſerably poor in the year 1794, after having been confined many years in conſequence of a paralytic attack. He was author of many uſeful and popular works. Of theſe the moſt important and intereſting are his "New Introduction to the ſtudy and knowledge of the New Teſtament," in two volumes 8vo. "Five Diſſertations on the Athanaſian and Socinian Schemes," the object of which was to prove the truth of Arianiſm. "The Life and Character of Jeſus Chriſt delineated:" and "A View of the various Editions of the Greek and Roman Claſſics," which has been ſeveral times reprinted, and has, as well as his "Introduction to the New Teſtament," been tranſlated into ſeveral foreign languages.

HARWOOD's *Iſland*, in *Geography*, a ſmall iſland in the gulf of Georgia, on the N. coaſt of the iſland of Favida. N. lat. 49° 50'. E. long. 235° 46'.

HAS, a town of Arabia Felix, in the province of Yemen, in the Tehama; capital of a diſtrict, and reſidence of a Dola, 40 miles N. of Mocha. A conſiderable quantity of earthenware is manufactured here, eſpecially coarſe drinking cups. The diſtrict is of narrow extent, being bounded on one ſide by Zebid, and on the other by the territories of the Scheick of Ibn Aklun. N. lat. 14° 58'. E. long. 43° 25'.

HASAB, a town of Candahar, in the province of Gaur, near the river Belaſe; 25 miles S.W. of Gaur.

HASAKLU, a town of Aſiatic Turkey, in Natolia; five miles N.W. of Beiſheri.

HASANI, a ſmall iſland in the Red ſea, near the coaſt of Arabia. N. lat. 24° 54'.

HASBET, a town of Egypt, on the E. ſide of the Nile; oppoſite to Roſetta.

HASCARA, a town of Morocco; 85 miles N. of Morocco.

HASCHID-U-BEKEL, an independent ſtate of Arabia, in the province of Yemen. This extenſive territory, named alſo "Bellad-el-Kobail," the country of the Highlanders, is poſſeſſed by a number of confederated Scheicks; but the other, expreſſive of the confederacy, is the name by which it is more commonly known. It extends northward as far as the deſert of Amaſia; on the S. and E. it is bounded by the dominions of the Imam and the principality of Kaukeban; and towards the W. it meets the ſovereign ſtate of Abu-Ariſch. This highland country contains many Scheicks, deſcended from ancient noble families, each of whom rules within his own dominions as a ſovereign prince; and yet, unable ſeparately to reſiſt any powerful neighbour, they have combined to defend themſelves by a common force. The country inhabited by theſe confederates poſſeſſes various degrees of fertility. Some vallies, which produce fruit in great abundance, are interſperſed among the hills, and even the higher grounds are cultivated and fertile. Cattle in conſiderable number are ſcattered upon the heights; but few conſiderable villages are to be ſeen. The town of Kheivan, in the diſtrict of the ſame name, is remarkable for having been the ſeat, firſt of the Hamjare monarchs, and afterwards of the Imams. Ruins of a very ancient palace are ſtill to be ſeen there.

HASE, THEODORE, in *Biography*, was born at Bremen in the year 1682, and educated under the moſt eminent profeſſors in the Dutch and German univerſities. In the year 1707 he was elected profeſſor of the belles lettres at the univerſity of Hanau, but in the following year he was recalled to his native city, where he received the appointments of miniſter of the church of St. Mary, and profeſſor of the Hebrew language in the univerſity. In 1712 he was created doctor of divinity, and in 1718 was choſen a member of the Royal Society of Berlin. He died in the year 1731, leaving behind him a collection of critical diſſertations, which were publiſhed after his death, in one volume octavo. Moreri.

HASEK, in *Geography*, a town of Perſia, in the province of Kerman; 40 miles S.E. of Kabis.

HASEK, or *Haſſek*, a town of Arabia, in the province of Hadramaut, 684 miles E.N.E. of Mocha; known only for the traffic which its inhabitants, as well as thoſe of "Merbat," carry on in incenſe produced in that neighbourhood.

HASEL, one of the ſmaller Hebrides, near the S. coaſt of Egg. N. lat. 56° 51'. W. long. 6° 3'.

HASELE, in *Ichthyology*. See CYPRINUS *Dobula*.

HASEL.

HASELHUHN, in *Ornithology*. See TETRAO *Bonaſia* and TETRAO *Mexicanus*.

HASELOE, in *Geography*, a ſmall iſland of Denmark, in the Cattegat; 12 miles from the iſland of Zealand. N. lat. 56 11'. E. long. 11 45'.

HASEN, a town of Pruſſia, in Natangen; 20 miles E.S.E. of Angerburg.

HASENMULLER, DANIEL, in *Biography*, was born at Eutin, a town in Holſtein, in the year 1651, where he received the elements of a learned education: and when he was about fifteen years of age he was ſent to Lubec to proſecute his riper ſtudies. He particularly excelled in his knowledge of the Greek and oriental languages, and was, in the year 1683, appointed to the profeſſorſhip of the Greek language at the univerſity of Kiel, to which was added that of the Hebrew and oriental languages. He died before he had completed his fortieth year, having previouſly illuſtrated his name by many learned works given to the public; of theſe we may notice "Diſſertatio de Linguis Orientalibus:" "Biblia parva Græca, in quibus dicta inſigniora omnia ex Verſione Septuagintavirali ſecundum Ordinem, Librorum biblicorum obſervatum in biblis parvis Opitianis, cum cura exhibentur:" and "Janua Hebraiſmi aperta." Moreri.

HASER, in *Geography*, a town of Egypt; 13 miles S.E. of Tineh.

HASFURT, a town of Germany, in the principality of Wurtzburg; 12 miles E. of Schweinfurt.

HASINELLAS, in the *Glaſs-making Trade*, are a number of hooks faſtened to the ſides of the working furnace, by means of which the workmen are able to reſt and turn their veſſels as they heat them. Neri's Art of Glaſs, p. 242.

HASJO, in *Geography*, a town of Sweden, in Medelpadia; 13 miles S.W. of Hernoſand.

HASK, a morbid condition which is attended with a ſort of huſky cough, affecting horſes, pigs, and ſome other kinds of animals. See HUSK.

HASLACH, in *Geography*, a town of Germany, in the lordſhip of Hauſen, on the Kinzig; 18 miles N.N.E. of Friburg.

HASLED, a town of Sweden, in the province of Weſt Gothland; 69 miles N.E. of Uddevalla.

HASLEMERE, a borough and market town, in the pariſh of Chidingford and hundred of Godalming, Surrey, England, was formerly a conſiderable place, but is now reduced to 144 houſes, containing a population of 642 perſons. It is an ancient borough by preſcription, and has ſent members to parliament ſince the 27th year of the reign of Elizabeth. The right of election is veſted in "the freeholders of meſſuages, lands, or tenements lying within the borough and manor." This property belongs to the earl of Lonſdale, by whoſe father it was purchaſed of Meſſrs. Chandler and Leach for the ſum of 24,000*l*. The number of voters is about 60. Like the generality of ſmall boroughs, this has been the ſubject of much litigation and parliamentary conteſt. In 1775 a cauſe was tried by a committee of the houſe of commons, reſpecting a complaint againſt the ſitting members "for ſplitting and dividing of freeholds." (Oldfield's Hiſtory of Boroughs, &c. vol. iii.) This town is ſeated at the border of the county, near its junction with Suſſex, and is deſcribed to have formerly had ſeven pariſh churches, which were deſtroyed by the Danes. Here are a ſmall market on Tueſdays, and two annual fairs. (Manning's Hiſtory, &c. of Surrey.)

HASLERUS, or HASLER, in *Biography*, is the name of an eminent muſical family that flouriſhed at Nuremberg, in the ſixteenth century, during three or four generations. They were not only able organiſts, but voluminous compoſers, chiefly of eccleſiaſtical muſic; and ſeem all ſucceſſively to have been patroniſed by the Fuggers of Augſburg, thoſe wealthy merchants and munificent encouragers of learning and the arts.

HASLI, in *Geography*, a diſtrict of Switzerland, in the canton of Berne, ſituated in a beautiful valley, S.E. of the lake of the Brientz, and watered by the Aar, and other ſmaller ſtreams. The inhabitants are well made, ſtout, and warlike, and the women are generally handſome. The principal wealth of this diſtrict ariſes from the ſale of cheeſe, which they ſend in great quantities to Italy. The chief town is Meyringen.

HASLINGDEN, a market town and chapelry in the large pariſh of Whalley and county of Lancaſter, England, is about 14 miles north of Mancheſter, and conſiſts of 844 houſes and 4040 inhabitants. Like moſt of the Lancaſhire towns, this contains ſeveral linen, cotton, and woollen manufactories, which within the laſt twenty years have occaſioned a great influx of inhabitants, and a large increaſe of buildings into the valley below the old town. By an inquiſition of the parliament commiſſioners in June 1650, this parochial chapelry conſiſted of the townſhip of Haſlingden and part of Roſſendale, which together contained about 300 families; in 1801 there were 773 families in this townſhip only. The government of the town is veſted in a conſtable and ſix churchwardens, who have under their care ſix diviſions or poſts; two of theſe have a chapel of eaſe, ſubject to Haſlingden, called Goodſhaw chapel, about two miles from the town on the Burnley road. From a ſpirit of induſtry and enterpriſe which pervades all ranks of perſons in this diſtrict, great improvements have taken place in the town; among others, a handſome ſquare is already completed, which contains ſome capital buildings. Eſſential advantages have been derived from the canals which afford the benefit of water-carriage for heavy articles, which formerly uſed to paſs many miles by land. A number of mills are eſtabliſhed on the river for carding cotton and wool, and for ſpinning them into twiſt and woollen yarn, to make flannels. (Whitaker's Hiſtory, &c. of Whalley, 4to.)

HASLINGDEN *Canal*. At the time of compiling our article CANAL, we gave an account of this intended canal, for which an act paſſed in 1793, but it does not appear that any ſteps have yet been taken towards its execution: it was intended for connecting the Mancheſter, Bolton, and Bury canal with the Leeds and Liverpool canal.

HASPARRAN, a town of France, in the department of the Lower Pyrenées, and chief place of a canton, in the diſtrict of Bayonne, ſeven miles S.E. of Bayonne. The place contains 4156, and the canton 8440 inhabitants, on a territory of 170 kiliometres, in 7 communes.

HASSA, a town of Nubia, 10 miles N. of Goos.

HASSA *alrhai*, in the *Materia Medica of the Arabian Phyſicians*, a name given to a plant, the virtues of which they commend on many occaſions.

The meaning of the words *haſſa alrhai* is *virga paſtoris*, ſhepherd's rod; but though it happens that the names of theſe two plants agree in ſignification, there is nothing elſe in which they agree, the haſſa alrhai being the ſame plant with the polygonum of the early writers, which, with the epithet of *maſculum*, ſtood for the common knotgraſs; and when the word *femininum* was added, ſignified the common *equiſetum*, or horſetail, which was called *polygonum*, for the ſame reaſon the knotgraſs was, that is, becauſe its ſtalks were compoſed of a great number of joints. Theſe two plants

plants agree in the virtues of agglutinants and aſtringents, to neither of which virtues our *virga paſtoris* has any title.

HASSADA, in *Geography*, a town of Bengal; 20 miles E. of Kiſhenagur.

HASSAN, in *Biography*, eldeſt ſon of Ali, by Fatima, daughter of Mahomet, was born in the third year of the hegira A.D. 625. He was advanced to the caliphate in 660 without any oppoſition, though the mildneſs of his temper ill fitted him for the turbulent ſcenes in which he was likely to be engaged. Scarcely had he aſcended the throne when he was obliged to contend with Moawtyah, at the head of a powerful army. The caliph was defeated and took refuge in a ſtrong caſtle, the governor of which was ſtrongly ſolicited to put Haſſan to death, which he peremptorily refuſed. Haſſan, ſhocked at the ſcenes of devaſtation and blood, to which he had been an eye witneſs, determined to abdicate his office; which he accompliſhed in the preſence of the general aſſembly of the people of Cufa, in the great moſque, and which he attributed to his anxious deſire of ſparing the blood of his people. He now retired to Medina with ample proviſion for his future ſupport. Of this he expended the greater part in acts of charity, ſometimes he did not even leave himſelf ſufficient to alleviate the common wants of nature. Twice he ſtripped himſelf of all he poſſeſſed, and thrice he divided half his ſubſtance among the poor. Haſſan paſſed eight years in a private condition, and obtained univerſal reſpect from his countrymen on account of his many virtues, and was venerated for his reſemblance to his grand-father Mahomet, who had been particularly kind to him, when he was a child. He died in the year 669: his death was imputed to poiſon. Being preſſed to name the perſon whom he ſuſpected of the foul deed, he replied "The life of this world is made up of nights that vaniſh away. Let him alone till he and I meet before the tribunal of God." Univer. Hiſt.

HASSAN, in *Geography*, a town of Africa, on the coaſt of Tripoly. N. lat 31. E. long. 16° 18'.—Alſo, a town of Perſia, in the province of Irak; 80 miles N.N.E. of Hamadan.

HASSAN, *Chillibec*, a town of Aſiatic Turkey, in the government of Sivas; 32 miles E. of Sivas.

HASSAN *Pacha Palanka*, a town of European Turkey, in Servia; 60 miles N.N.E. of Novibaſar.

HASSE ADOLFO, *detto il* SASSONE, in *Biography*, from his having been born at Bergendorf in Lower Saxony, within eight miles of Hamburgh.

Quantz relates, in his own memoirs written by himſelf, that in the year 1725, he went to Naples, where he met with his countryman Haſſe, who then ſtudied under Aleſ. Scarlatti. Haſſe had not, as yet, diſtinguiſhed himſelf by any compoſitions for the ſtage; however, it was at this time, that a conſiderable Neapolitan banker employed him to ſet a ſerenata for two voices, which he did in the preſence of Quantz; the ſingers who performed in it were Farinelli and Teſi. Haſſe gained ſo much reputation by this production, that it paved the way to his future ſucceſs, and he was ſoon after appointed compoſer of the great opera at the theatre royal.

Quantz intreated Haſſe to introduce him to his maſter, Scarlatti, to which he readily conſented; but upon mentioning him to the old compoſer, he ſaid, "My ſon, you know I hate wind inſtruments, they are never in tune." However, Haſſe did not ceaſe importuning him, till he had obtained the permiſſion he required.

In 1726, the year after the deceaſe of his maſter Aleſſandro Scarlatti, he had diſtinguiſhed himſelf ſufficiently to be called upon to ſet the opera of "Seſoſtrate" for the great theatre at Naples; and in 1728 he ſet "Attalo Re di Bitinia," for the ſame theatre. Theſe two operas ſeem to have been forgotten by the compoſer himſelf, in the verbal enumeration of his works, which we obtained from him at Vienna in 1772. But we are in poſſeſſion of the printed book of the words of both theſe dramas, with the above dates, to which his name is prefixed in the following manner: "La Muſica è del Signor Giovanni Adolfo Haſſe detto il Saſſone, Maeſtro di Capella di S. A. S. il Duca di Brunſwick;" the record is indiſputable. In 1730 he ſet two operas for Venice, "Daliſa," in which the principal ſingers were Paſi, Amorevoli, and Fauſtina, whom he married about this time; and "Artaſerſe," written by Metaſtaſio, in which the principal parts were performed by Farinelli and Cuzzoni. In one of theſe he is called maeſtro ſopranumerario of the royal chapel of Naples; and in the other maeſtro di capella of Auguſtus, king of Poland, and elector of Saxony. In 1732 he compoſed "Cajo Fabricio" for Rome; and "Demetrio" for Venice. Theſe dramas, particularly the two written by Metaſtaſio, and the great ſingers who performed in them, eſtabliſhed his reputation, which extended to every part of Europe.

Haſſe was the favourite compoſer of Italy and Germany from the year 1730 to 1755. He and the Fauſtina were in the ſervice of the court at Dreſden, till it was beſieged by the king of Pruſſia, when, in the bombardment of that city, all his books, manuſcripts, and effects were deſtroyed by fire.

The abilities of this admirable vocal compoſer are but little known in England, as but few of his beſt compoſitions are printed, and thoſe, except his "Salve Regina," of the moſt trivial kind. However, the comic dances which he compoſed for the Fauſans ſhewed that he could trifle with grace. His air, "Pallido il Sole" is ſtill heard with pleaſure, though more than 70 years old. On aſking Metaſtaſio what maſter, of all the compoſers who had ſet his dramas to muſic, had expreſſed his ideas the moſt to his ſatisfaction, he replied, "though he is not my countryman, I believe it was Saſſone." But his merit was ſo long and ſo univerſally eſtabliſhed on the continent, that we never converſed with a ſingle profeſſor on the ſubject, who has not allowed him to be the moſt natural, elegant, and judicious compoſer of vocal muſic, as well as the moſt voluminous compoſer of his time: equally a friend to poetry and the voice, he diſcovered as much judgment as genius in expreſſing words, as well as in accompanying his ſweet and tender melodies. Always regarding the voice, as the firſt object of attention in a theatre, he never ſuffocates it by the learned jargon of a multiplicity of inſtruments and ſubjects; but is as careful of preſerving its importance as a painter, of throwing the ſtrongeſt light upon the capital figure of his piece.

As a proof how little we are acquainted with the works of Haſſe in England, though he ſet all the ſerious dramas of Metaſtaſio, except "Temiſtocle," many of them two or three different times, to diſplay the talents of different ſingers; yet out of the whole number of his operas, amounting to more than 100, we never heard one of them performed entire on our ſtage, except, in 1757, "Artaſerſe," in which Farinelli firſt appeared in London, was ſuppoſed to be wholly the work of Haſſe; but ſeveral of the ſongs, particularly the famous bravura air *Son qual Nave*, were compoſed by Riccardo Broſchi, the brother of Farinelli.

Beſides operas, Haſſe compoſed oratorios, maſſes, motets, and chamber duets, in the ſtyle of Steffani, innumerable. So that it may be ſafely averred, that in fertility and variety of works, he ſurpaſſed every compoſer of the laſt century, except Galuppi and Piccini.

We ſhall add nothing more to our account of the genius and abilities of this elegant and intelligent maſter, except the melancholy record of his death, at Venice, in 1784, whither he had retired with his wife, the Fauſtina, and two accompliſhed daughters, in 1783, to terminate his ſplendid and active life in peace and tranquillity.

HASSEIAH, in *Geography*, a town of Syria, in the pachalic of Damaſcus, governed by an Aga; 52 miles N.E. of Damaſcus.

HASSELA, a town of Sweden, in the province of Helſingland; 26 miles N.W. of Hudwickſwal.

HASSELOE, a ſmall iſland of Denmark, between Laaland and Falſter. N. lat. 54° 44'. E long. 11° 54'.

HASSELQUIST, Frederick, in *Biography*, one of the favourite pupils of Linnæus, and eminently diſtinguiſhed by his illuſtrations of the natural hiſtory and medicine of the Levant, was born at Toernvalla, in Eaſt Gothland, Jan. 3d, 1772, old ſtyle. He was the ſon of a poor curate, who died at an early age, and whoſe widow, on account of mental and corporeal infirmities, was obliged to be placed in the hoſpital at Vadſtena. Her brother, a worthy clergyman of the name of Pontin, took pity upon the orphan, and educated him, with his own children, at the ſchool of Linkoeping; bnt Haſſelquiſt was ſoon deprived of this beneſactor, and the learning he had by this time acquired was now his only reſource. He was obliged to become the tutor of young children till he was old enough to go to the univerſity. By a ſimilar plan he was enabled to ſupport himſelf after he entered at Upſal in 1741, inſtructing ſuch as knew leſs than himſelf, for trifling gratifications, while on the other hand he made the beſt uſe of the advantages he there enjoyed for his own improvement. He ſoon took a decided turn for phyſic and natural hiſtory, and had ſome talents for poetry. His diligence did not paſs unobſerved nor unrewarded, and his ſuperiors procured him, in 1746, a royal ſtipend or ſcholarſhip. In June, 1747, he publiſhed his theſis, entitled *Vires Plantarum*, under the preſidency of Linnæus, who ſays, "he wrote it well and defended it ſtrenuouſly." This is reprinted in *Amoen. Acad.* v. 1. 418, and in ſeveral other places. It is one of the beſt of the Linnæan diſſertations, ſetting forth the erroneous and often fooliſh principles on which plants had formerly been employed in medicine, and ſuggeſting a truly philoſophical one in their natural botanical affinities. The whole is illuſtrated by innumerable facts and illuſtrations, often very ingenious, and at leaſt as accurate as moſt medical writings of that day. This eſſay is a commentary on the 12th chapter of the *Philoſophia Botanica*, and has been made much uſe of by Mr. Roſe in his Elements of Botany, p. 404—438.

In one of his botanical lectures in 1747, Linnæus ſpoke of the countries of whoſe natural hiſtory little or no account had as yet been communicated to the learned world. Among theſe, he obſerved, was Paleſtine, one of the moſt important and intereſting in this reſpect, to the philoſopher as well as the divine, but of whoſe productions we had leſs knowledge than of thoſe of India. This remark fired the zeal of young Haſſelquiſt. In vain did his preceptor, ſecretly delighted with his enthuſiaſm, repreſent to him the difficulties of the undertaking, the diſtance, the dangers, the expence, and above all the weak ſtate of his own health, particularly of his lungs. All this did but increaſe his ardour, and he, in his turn, repreſented the benefit his conſtitution was likely to derive from a change of climate, in a pulmonary complaint. With reſpect to all other impediments, he declared he would rather walk all the way than have his purpoſe croſſed. Had he read Shakſpeare, he would doubtleſs have ſaid, he was ſo enamoured with ſcience that he would go "barefoot to Paleſtine for a touch of her nether lip."

Haſſelquiſt's firſt ſtep was to ſolicit aſſiſtance from certain funds deſtined for the ſupport of travellers, but he was unſucceſsful. He obtained indeed ſome private ſubſcriptions, and the various profeſſors at Upſal beſtowed upon him ſeveral of the royal ſtipends appropriated to the aſſiſtance of indigent ſcholars. Of the amount of the whole we are not informed, but it is repreſented as far inadequate to his undertaking. He began, however, to learn the oriental tongues, at the ſame time that he was completing his academical ſtudies, reading lectures, and obtaining the degree of licentiate in phyſic. The faculty, conſidering his merit and circumſtances, would not allow him to be at any expence on this occaſion, any more than for his attendance on the lectures of the profeſſors. The degree of doctor of phyſic was afterwards conferred on him during his abſence at Cairo, March 8th, 1751, with the ſame honourable and delicate attention to his peculiar ſituation. In the ſpring of 1749 he went to Stockholm, read lectures on botany there during the ſummer, and ſo far recommended himſelf to public notice, that the company of merchants trading to the Levant, offered him a free paſſage to Smyrna in one of their ſhips, in which he ſet ſail Auguſt 7th, arriving at Smyrna on the 27th of November, 1747. He kept a regular journal of his voyage. Touching at Gottenburgh, he there met Toreen, juſt returned from China with abundance of treaſures for his maſter Linnæus, in whoſe works they have at various times been communicated to the public.

At Smyrna Haſſelquiſt met with the kindeſt reception from his relation, Mr. Rydelius, the Swediſh conſul, as well as from the French conſul, M. Peyſonel, one of the firſt who ſuſpected the animal nature of corals. He ſpent the winter in noticing every thing he could meet with, reſpecting the main objects of his purſuit, in this place and its neighbourhood, as well as the religious ceremonies and manners of the people. He viſited the houſe and garden, once occupied by the famous Sherard, at Sedekio, near Smyrna, but found no traces of any great care having been taken to adorn the garden, or to ſtore it with exotic plants. He made an excurſion to Magneſia, his quality of phyſician cauſing him to be received every where with reſpect. As the ſpring advanced he became deſirous of extending his enquiries, and early in May ſet ſail for Alexandria, where he arrived on the 13th. Here the palm-trees, which now firſt preſented themſelves to his notice, excited him to enquire into and to verify the celebrated hiſtory of their artificial impregnation, of which he wrote a full account to Linnæus. Having ſpent two months in ſeeing all he could at Alexandria, Roſetta, and Cairo, he viſited the Egyptian pyramids in July, brought from thence *Chondrilla juncea*, the only plant he could find, which is now in the herbarium of his preceptor, was hoſpitably entertained by the Arabs, and returned ſafe to Cairo, where he had afterwards an opportunity of ſeeing the caravan depart for Mecca, of which he has given an ample and intereſting deſcription, as well as of many other feſtivals and exhibitions. He viſited the catacombs, and examined many mummies of the ancient *Ibis*, by the ſize of which he was induced to take this famous bird to be a ſpecies of *Ardea*, common and almoſt peculiar to Egypt, very different from the *Tantalus Ibis* of

Linnæus.

Linnæus. The learned Cuvier, however, has recently ſhewn that naturaliſts have been widely miſtaken on this ſubject, Mr. Bruce alone having indicated the real *Ibis*, in his vol. 5. 172, which is a ſpecies of Curlew hitherto ſcarcely known to naturaliſts, and now called by Cuvier *Numenius Ibis*, in Ann. du Muſeum d'Hiſt. Nat. v. 4. 116, t. 52, 53. It is the *Tantalus æthiopicus* of Latham, Ind. Ornith. 706. A great objection to this determination is the weakneſs of its bill, which ſeems by no means ſo fit as that of an *Ardea* for the mode of life which rendered it ſo famous, the deſtruction of reptiles. Cuvier, however, removes this doubt, by aſſerting that he found the remains of a ſerpent's ſkin in one of the mummies of the *Ibis*. After all, though numbers of other birds of the ſame natural family were doubtleſs employed every ſeaſon in feeding on reptiles, at the receſs of the Nile, the *Ibis* might be ſelected for protection and for divine honours, either, as Cuvier ſuggeſts, becauſe it fed on ſome peculiarly noxious, though not large animals of that kind; or for ſome ſuperſtitious reaſon, forgotten in the lapſe of ages, equivalent to no reaſon at all.

Haſſelquiſt proceeded in March, 1751, to Damiata, whence he ſailed for Jaffa, or Joppa, and arrived there after a voyage of four days. He had now reached the great theatre of his enquiries, the Holy Land, and he entered upon the examination of its productions, and their ſacred as well as medical hiſtory, with all the zeal which had at firſt prompted him to the journey, and which was crowned with eminent ſucceſs. Having ſpent near two months in this celebrated country, he ſailed from Seide the 23d of May, for Cyprus, from whence he proceeded to Rhodes, and to Stanchio, the ancient Cos, finally returning to Smyrna in the end of July.

From time to time, in the courſe of his travels, he had written to Linnæus, and had ſent home various natural curioſities, as well as ſeveral diſſertations, which were printed in the Tranſactions of the Upſal and Stockholm Academies. Nine appear in a volume of the former, in 1751. Theſe are on the *Mimoſa Lebbeck*, Linn. Sp. Pl. 1503, which is the *ſpecioſa* of Jacquin's Ic. Rar. t. 198; on the *Cervus Camelopardalis*; *Mus Jaculus*; *Turdus Cyanus*; *Fulica atra* taken at Smyrna; *Coluber Vipera*, the true officinal viper, for which our *C. Berus* had always previouſly been miſtaken; *Coluber Ceraſtes*, or horned viper; *Anguis Ceraſtes*, horned ſnake; *Lacerta Scincus*, the famous reſtorative lizard of the Arabs; and *Sepia octopodia*, eight-armed cuttlefiſh, the celebrated enemy of the great muſcle *Pinna muricata*, which laſt is warned of its approach by one or more little crabs, that always reſide within its ample ſhell, and are thus protected from external danger in their turn. In the Stockholm Tranſactions for 1750, 1751, and 1752, Haſſelquiſt wrote on the eruptive diſeaſe called the Aleppo mark; on the Egyptian vulture, *Vultur Percnopterus*; on the preparation of ſal ammoniac in Egypt; on the uſe of locuſts as food in Arabia, ſhowing that the paſſage of ſcripture, which mentions ſuch as the food of St. John in the deſart, is to be literally underſtood; and finally, another paper on the *Mus Jaculus*, or Jerboa, the *Dipus Jaculus* of later writers. His Letters to various friends were occaſionally printed, in a periodical publication called Literary News, at Stockholm; and in return for the entertainment and information he gave his countrymen, they contribnted ſome neceſſary ſupplies towards his expenſive undertakings. Unfortunately he had, in the meanwhile, ſacrificed, inſtead of reſtoring his health. "The ſerpent he had long harboured in his boſom," to uſe the emphatic words of Linnæus, "awoke." He flattered himſelf, as all in his condition do, and thought that a winter's repoſe at Smyrna might reſtore him. He tried the country air and a milk diet, but he "waſted away daily, like a lamp whoſe oil is ſpent, and departed this life, Feb. 9, 1752, at ſix in the evening, to the inexpreſſible grief of all who knew him," in the 31ſt year of his age.

In the courſe of his expenſive journies and his illneſs, this unfortunate young man had unavoidably incurred debts beyond what his caſual ſupplies from home could liquidate; and the collections and manuſcript notes, which ſtill remained at Smyrna, were ſeized by his creditors, for a ſum amounting to 14,000 dollars of copper-money, or about 350*l.* ſterling. This circumſtance was no ſooner made known, through Linnæus and his friend Bæck, to the accompliſhed queen of Sweden, Louiſa Ulrica, the worthy ſiſter of the great Frederick of Pruſſia, than ſhe immediately redeemed theſe treaſures out of her own purſe, gave Linnæus all the duplicates, and commiſſioned him to arrange and publiſh the manuſcript journal and remarks of his deceaſed pupil; a taſk which he undertook with alacrity, and executed with care and judgment. Theſe papers were given to the public in 1757, in Swediſh, except ſeveral Latin deſcriptions, under the title of *Iter Palæſtinum*, or a Journey to the Holy Land, in one volume 8vo. with a biographical preface by Linnæus, who ſubjoined to the work the very intereſting letters of Haſſelquiſt to himſelf. This book has been tranſlated into ſeveral languages, and appeared in Engliſh, at London, in 1766; but this tranſlation is in many parts defective, eſpecially with regard to the natural hiſtory and the ſcientific names, and being become very ſcarce, a new and improved edition is much wanted, to which a good index would be a valuable addition. In 1758 the above mentioned Dr. Bæck, phyſician to the queen, publiſhed, at Stockholm, an oration in praiſe of Haſſelquiſt, in 8vo.

Haſſelquiſt muſt ever rank high as an original and faithful obſerver, not only in his own immediate line of ſtudy, but in whatever came before him. His illuſtrations of the natural hiſtory of Scripture are above all things valuable and correct. Far leſs prone to go learnedly and ingeniouſly aſtray than his diſtinguiſhed countryman Olaus Celſius, in the *Hierobotanicon*, he has, by accurate obſervation and plain ſenſe, cleared up many difficulties, which commentators, without the former, and diſdaining the latter, have often embroiled. Haller, in his Bibl. Bot. v. ii. 403, has given Haſſelquiſt due praiſe, but is ſcarcely correct in ſaying he has "ſomething concerning caprification, where he doubts of the Linnæan fecundation." This might ſeem to imply that our author doubted of the ſexes of plants; but Haller certainly only meant that he doubted of the manner in which Linnæus thought the fecundation of the fig was accompliſhed by inſects, which Tournefort ſaw, and yet would not admit the doctrine of the ſexes. See CAPRIFICATION, and FICUS, n. 105. Haſſelquiſt's obſervations, however, by no means invalidate the one more than the other. He remarks indeed that the *Cynips Pſenes*, Linn. Syſt. Nat. ed. 12. v. 1. 919, by eating the germens of the *Ficus Carica* does more harm than good; and in his letter of September, 1750, to Linnæus, in ſpeaking of *F. Sycomorus* and the *Cynips* which inhabits its bloſſoms, he ſays he "has much reaſon to doubt whether this inſect contributes any thing towards its fecundation, but will make ſome farther inquiry." To the firſt remark of Haſſelquiſt it may be anſwered, that, though many of the germens are devoured by the inſect, probably none at all would be impregnated without its help; and the latter doubt, to which Haller ſeems to allude, is removed in the botanical part of the book, under *Ficus Sycomorus*, where, while an original account is given of a ſpontaneous gangrenous ſpot in that fruit, by which its bloſſoms become expoſed, the aſſiſtance of the *Cynips Sycomori* in fecundating it is expreſsly admitted. Curious ſpecimens of this minute animal, ſent by Haſſelquiſt, from

from Cairo, are preſerved in the Linnæan cabinet. Theſe are gummed on a peculiar very delicate ſubſtance, by way of paper, with whoſe hiſtory and origin we are unacquainted, though it is now ſold in London, of various colours, in ſmall ſquare pieces, for making artificial flowers, for which its texture is admirably calculated.

A rude attack has been made by the celebrated Buffon upon Haſſelquiſt's deſcription of the *Camelopardalis* in particular, and the *Viverra Ichneumon*. As nothing to the purpoſe is ſaid againſt either of his accounts, though the Latin of Haſſelquiſt is copied ſo erroneouſly as to be made abſolute nonſenſe, and then criticiſed for its ſtyle; and as the attack evidently originates in Buffon's antipathy to the whole Linnæan ſchool, it ſcarcely merited the honour of ſo ample a refutation as Dr. Sparrmann has beſtowed upon it, in his voyage to the Cape of Good Hope, chapter 14th. To have been a pupil of Linnæus, a ſyſtematic naturaliſt, a man of religion, probity, and morality, might well excite the ſpleen of the man who dared to allow that "his own genius was equal to the majeſty of nature;" but ſuch qualities will ever embalm the memory of Haſſelquiſt, who might be content to yield to the French philoſopher without a ſigh of regret, all that the latter ever aſſumed, and even all he deſerved. Haſſelquiſt's Works. Haller's Bibl. Bot. S.

HASSELQUISTIA, in *Botany*, ſo named by Linnæus in juſt commemoration of his pupil, Frederick Haſſelquiſt, M.D. its diſcoverer. See the preceding article. Linn. Gen. 135. Schreb. 180. Willd Sp. Pl. v. 1. 1379. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 1. 332. Sm. Prod. Fl. Græc. v. 1. 180. Juſſ. 224. Gærtn. t. 21. (Tordylium; Lamarck. Illuſtr. t. 193. f. 2.)—Claſs and Order, *Pentandria Digynia*. Nat. Ord. *Umbelliferæ*.

Gen. Ch. *General umbel* of about ten ſpreading rays, of which the five outermoſt are longeſt; *partial* of twice as many, the outermoſt longeſt, incurved. In the place of the central partial umbel, is a ſtalked, capitate, black, fleſhy, abortive body, downy and whitiſh at the top. *General Involucrum* very ſmall, of five or more awl-ſhaped reflexed leaves; *partial* halved, of three awl-ſhaped reflexed leaves to the outer umbels, of one only to the inner ones. *Perianth* very minute, of five teeth. *Cor. Univerſal*, irregular, radiated, both in the general and partial umbels; flowers of the diſk either male, or abortive as in the general umbel; *partial* of five unequal, ſpreading, inflexed and variouſly cloven petals. *Stam.* Filaments five in each flower, capillary, longer than the ſmaller petals; anthers roundiſh. *Piſt.* Germen inferior, turbinate, compreſſed; ſtyles two, thread-ſhaped, the length of the ſtamens, erect, preſent in almoſt all the flowers; ſtigmas obtuſe. *Peric.* none. *Fruit* of the *circumference* nearly orbicular, ſmooth, compreſſed almoſt flat, thickened at the edge, notched at the baſe and ſummit, ſeparable into two parts; of the *diſk* ſemigloboſe, ſmooth, deeply concave on one ſide, with a contracted crenate orifice. *Seeds* two in the fruit of the circumference, one in that of the diſk.

Eſſ. Ch. General and partial involucrum of ſeveral leaves. Flowers radiant; thoſe of the diſk male; central abortive. Fruit of the radius orbicular, flat, crenate; of the diſk urceolate, hemiſpherical, ſingle-ſeeded.

Obſ. Adanſon and Lamarck conſider this genus as a *Tordylium*, with partially imperfect flowers and fruit; in which they are right, provided ſexual, and conſequently ſeminal, differences be not taken into conſideration at all in defining genera of the umbelliferous order. But if the Linnæan principles be ſolid, for which, in this caſe, we can by no means ſtrenuouſly contend, the genus of *Haſſelquiſtia* is as diſtinct as any of its tribe; and indeed the difference of its ſeeds is ſo ſtriking and peculiar, as to afford a ſtrong argument in favour of thoſe principles. The ſpecies are two.

1. H. *ægyptiaca*. Linn. Sp. Pl. 355. Suppl. 179. Jacq. Hort. Vind. v. 1. 37. t. 87.—Leaves pinnate; leaflets pinnatifid, cut.—Gathered by Haſſelquiſt in Arabia. Linn. Am. Acad. v. 4. 270. Miller cultivated it at Chelſea in 1768 or earlier, as appears by the eighth edition of his Dictionary, but it is not now preſerved in the gardens, being an annual or biennial of a tender conſtitution, and, though very curious to a botaniſt, not likely to attract mere amateurs. The *ſeeds* however are rather a ſtriking object. The *ſtem* is a foot or two high, erect, branched, leafy, furrowed, more or leſs rough with deflexed hairs. *Leaves* light green, of three or four pair of wedge-ſhaped, pinnatifid and cut ſmooth leaflets, with an odd one. *Umbels* terminal, erect, broad, flattiſh. *Flowers* white. Buxbaum's *Paſtinaca orientalis, foliis eleganter inciſis*, Cent. 3. 16. t. 27, is deſcribed with yellow equal petals, and heart-ſhaped ſtriated ſeeds, ſo that it cannot belong to the *Haſſelquiſtia*, though cited doubtingly by Linnæus.

2. H. *cordata*. Jacq. Hort. Vind. v. 2. 91. t. 193. Linn. Suppl. 179.—Leaves heart-ſhaped, crenate; ſimple or ternate.—The native country of this ſpecies is unknown. Jacquin received its ſeeds from the Swiſs botaniſt, Mr. Dick, who had them from Spielmann, and he ſays they agreed exactly with thoſe of the former, except in being one-third ſmaller. Gærtner however repreſents them as ſcarcely crenate. The *root* is annual. Whole plant pale green and downy, diſtinguiſhed from moſt of the umbelliferous tribe by its broad heart-ſhaped crenate *leaves*, which ſtand on long ſheathing ſtalks, ſometimes bearing a pair of rather narrower leaflets alſo. The *flowers* are white, in more compact umbels, the leaves of their general involucrum more numerous and conſpicuous, than in the former.

HASSELT, in *Geography*, a town of France, in the department of the Lower Meuſe, and principal place of a diſtrict, divided by the river Damar into two parts, one of which is in the county of Campine, the other in Looz; 16 miles N.N.W. of Liege. The place contains 5824, and the canton 12,001 inhabitants, on a territory of 95 kiliometres, in 6 communes. N. lat. 50° 56′. E. long. 5° 23′.—Alſo, a ſmall but handſome town of Holland, in Overyſſel, ſituated on the Vecht; 10 miles E. of Campen. N. lat. 52° 38′ E. long. 6° 1′.

HASSELWICK, a town of Norway, in the dioceſe of Drontheim; 18 miles N.N.W. of Drontheim.

HASSI, a town of European Turkey, in the province of Macedonia; 56 miles N.N.W. of Akrida.

HASSLACH, a town of Germany, in the biſhopric of Bamberg; 24 miles N.N.E. of Bamberg.

HASSOCK, denotes a baſs, or cuſhion made of ruſhes, to kneel or reſt the feet on in churches.

HASTA, or HASTA PURA, among *Medaliſts*, ſignifies a kind of ſpear or javelin, not ſhod, or headed with iron; or rather an ancient ſceptre, ſomewhat longer than ordinary, occaſionally given to all the gods.

The haſta is ſuppoſed a ſymbol of the goodneſs of the gods, and of the conduct of providence, which is equally mild and forcible.

HASTA, in ſome countries, is a meaſure, or quantity of ground amounting to thirty paces: thus called, according to M. Du-Cange, from the haſta, or rod, wherewith it was meaſured.

HASTATI, or HASTARII, among the *Romans*, ſoldiers armed with ſpears, who were always drawn up in the firſt line of battle.

HASTATUM, FOLIUM, in *Botany*, a halberd-ſhaped leaf, conſiſting of an oblong central lobe, with two tranſverſe, uſually ſmaller, lobes at its baſe. See LEAF.

HASTE, or QUICKEN *your Hand*, in the *Manege*, called in French *hatez le main*, or *hatez, hatez*, is an expreſſion frequently uſed by riding-maſters, when a ſcholar works a horſe upon volts, and the maſter has a mind he ſhould turn his hand quicker to the ſide on which the horſe works; ſo that if the horſe works to the right, he turns quicker with his ſhoulders to the right: and the contrary is obſerved, if the horſe works to the left.

HASTING-PEAR, a name given, by the gardeners, to a ſpecies of pear, called alſo by ſome the green chiſſel pear; this is a moderately large pear, and is longiſh towards the pedicle: its ſkin is thin, and of a whitiſh green; the pulp is melting, and of a ſugary flavour. It ripens in July.

HASTINGIA, in *Botany*, ſo named by the late Dr. John Gerard Koenig, long employed in botanical reſearches at Bengal, in honour of his patron, the celebrated governor Warren Haſtings. This deſign, however, has hitherto proved abortive, the firſt genus choſen for the purpoſe being the *Abroma* of Jacquin, Linnæus, and Schreber; ſee ABROMA; and the ſecond being publiſhed by Retzius, under the uncouth name *Holmſkioldia*, by which we ſhall hereafter notice it. See Sm. Exot. Bot. t. 80, and Introd. to Botany, 403.

HASTINGS, in *Geography*, a borough and market-town in the hundred of Baldſtow, and rape of Haſtings, in the county of Suſſex, England, conſiſts of three pariſhes, which contain 562 houſes, and 2982 inhabitants. The town is ſeated between two hills, on the coaſt, near the eaſtern extremity of the county, and being the chief of the cinque-ports, thence derives peculiar privileges and immunities. The hiſtory and peculiar nature of theſe ports have been already explained in the eighth volume of this work. This place appears to have been occupied by the Saxons, if not previouſly by the Romans. King Athelſtan is ſaid to have had a mint here. Camden, however, attributes the origin of the town to a noted Daniſh pirate, who conſtructed a fort here to protect his men, and ſecure a retreat after pillaging the ſurrounding country. Soon after the Norman conqueſt, it is evident that a caſtle was ſtanding here, as it is noticed in the time of William Rufus. This caſtle, and the original town, are ſaid to have been undermined, and carried away by the ſea, which continually encroaches on this coaſt; and a ſubſequent town is ſtated to have been burnt by the French in 1377. After its re-creation, it was divided into three pariſhes. Different charters have been granted to the town by Edward the Confeſſor; Williams I. and II.; Henry II.; Richard I.; Henry III.; Edward I.; Elizabeth; Charles II.; and James II. Haſtings has ſent members to parliament ever ſince the reign of Edward III.; and has generally been under the immediate controul and command of miniſters. The right of election was declared, in 1698, to be veſted in "the mayor, jurats, and freemen, reſident and not receiving alms, only." This number is twelve. Few boroughs have manifeſted a more corrupt ſyſtem, or been more the ſubject of political contention, than this: and in reviewing its hiſtory for the purpoſe of narrating it in an important national publication, we muſt lament the proſtitution of freedom, and deeply regret the corruption, political debaſement, and depravity of thoſe men who are entruſted with franchiſes, and who barter the independence of their country for a diſgraceful ſubſiſtence. A full account of the political hiſtory of this place is preſerved in Oldfield's Hiſtory of Boroughs, &c. vol iii. p. 27—47.

The town was formerly fortified with a wall, ſome ſmall remains of which are yet ſtanding. On a hill, eaſtward of the town, are the banks and foſſes of an encampment, which ſome authors aſcribe to the Romans, but it was moſt probably formed by William, duke of Normandy, previous to his battle with Harold. On the edge of the cliff, weſtward of the town, are the walls, &c. of an ancient caſtle, which was formerly of great extent, and muſt have been of great importance. Within its walls was a free royal chapel: the dean of which obtained a patent from Edward III. to build himſelf a manſion contiguous to it. Near the caſtle a priory for black canons was founded in the time of Richard II. Some fragments of the walls now remain. The harbour, now called the Stade, was formerly a place of commerce and ſecurity for veſſels, but in the time of queen Elizabeth the pier was deſtroyed by a ſtorm, and has never ſince been reſtored. Sloops and cutters, from 50 to 100 tons burthen, are the only veſſels that put in here. At the weſt end of the Stade is a fort, mounted with eleven twelve-pounders. Though the trade of this place has been much reduced, yet a large quantity of herrings, mackarel, and trawl-fiſh is annually caught near it, and brought into the town. Some fiſhing and long boats are built here. The town has weekly markets on Wedneſdays and Saturdays, and three annual fairs. The coaſt, being ſandy and clean, is favourable for bathing, and ſeveral machines are kept. The Haſtings Guide, 8vo. 1797.

HASTINGS, *Battle of*, a memorable event in the annals of Engliſh hiſtory, was fought between William, duke of Normandy, and Harold II., king of England, on the 14th of Oct. 1066. The Norman invader had landed his ſoldiers, horſes, ſtores, &c. at Pevenſey, on the coaſt of Suſſex, on the 29th of September, and after conſtructing a fort there, for the protection of his fleet, marched his army to Haſtings, where the whole continued to be actively employed in fortifying an encampment, collecting proviſions, and making other preparations for ſelf-defence, and for military operations. At the arrival of William in England, his adverſary Harold was ſeated with his army at York, but marched from that city as ſoon as he was appriſed of the event, and proceeeded, without halting, to the Suſſex coaſt. By rapid marches, deſertion, &c. his force was conſiderably diminiſhed; but in ſpite of ſuch diſadvantages, he very imprudently and unwiſely reſolved to riſk a battle the next day after his arrival on the downs near Haſtings. Both armies were drawn up in regular lines, and both prepared for a ſtubborn conteſt and decided iſſue. The Engliſh were all on foot, armed with ſwords, ſpears, and battle-axes; and formed themſelves into one deep and compact body; in the centre of which the king, with his brothers Gurth and Leofwin, placed themſelves with the royal ſtandard. The Normans formed in two lines, the firſt compoſed of archers and ſlingers, and the ſecond of heavy-armed troops; whilſt the cavalry, commanded by the ambitious invader, were ſtationed in the rear and at the wings. (W. Pictavin, p. 201, and Matthew Paris, p. 3.) On a ſignal given, the Normans ruſhed forward, and diſcharged a ſhower of arrows on their opponents; and the Engliſh not only ſuſtained the firſt aſſault, but retaliated with equal vigour and obſtinacy. The conflict was deſperate and ſanguinary: whilſt one party was irreſiſtibly impelled by the proſpect of gaining a country, or loſing life; the other was determined to riſk the latter in defence of their homes, their friends, and families. The Normans, however, being ſuperior in numbers, with the advantages of cavalry, ſcite of ground, and vigour of troops, after a whole day's fight, completely conquered the

Engliſh. The ſlaughter was great, and the victory complete. Harold, his two brothers, and many of the Engliſh officers, were ſlain, and the remaining troops diſperſed. Some hiſtorians aſſert, that no leſs than 15,000 Normans fell on the field of battle, and a larger number of their adverſaries. This, however, ſeems a little exaggerated. In obtaining this victory, William ſecured an eaſy paſſage to the throne; and after reſting and refreſhing his army for a few days, marched towards London. In this journey he had to encounter ſome impediments; but in a ſhort time he reached the capital, and was elected to the Engliſh throne. For other particulars relating to the conqueſt and acceſſion of William I., ſee CONQUEST, vol. ix.; ENGLAND, *Hiſtory of*, vol. xiii.; and BATTLE-ABBEY, vol iv. Henry's Hiſt. of Great Britain, vol. v. and Miller's Hiſtorical View of the Engliſh Government, vol. ii.

HASTINGS, a county in Upper Canada, bounded on the E. by the county of Lenox, on the S. by the bay of Quinte, and comprehending all the iſlands near it in the ſaid bay and river Trent.

HASTING'S *Bay*, a bay on the N.E. coaſt of the iſland of St. Matthew, in the Mergui Archipelago, diſcovered by Capt. Forreſt in 1783, and called by him one of the fineſt harbours in the world.

HASTING'S *Iſland*, an iſland in the Mergui Archipelago, near the N. coaſt of the iſland of St. Matthew, about four miles long, and two miles in its greateſt breadth. N. lat. 10° 6'.

HASTIVE, a French term, ſometimes uſed in Engliſh for *early*, *forward*, or ſomething that comes before the ordinary time or ſeaſon.

The haſtive fruits are ſtrawberries and cherries. We have haſtive peas, &c.

HAT, a covering for the head, worn by the men throughout the weſtern part of Europe.

Hats are chiefly made of hair, wool, &c. worked, fulled, and faſhioned to the figure of the head.

Hats are ſaid to have been firſt ſeen about the year 1400, at which time they became of uſe for country wear, riding, &c. F. Daniel relates, that when Charles II. made his public entry into Rouen, in 1449, he had on a hat lined with red velvet, and ſurmounted with a plume, or tuft of feathers: he adds, that it is from this entry, or at leaſt under this reign, that the uſe of hats and caps is to be dated, which henceforward began to take place of the chaperoons and hoods that had been worn before. In proceſs of time, from the laity, the clergy alſo took this part of the habit, but it was looked on as a great abuſe, and ſeveral regulations were publiſhed, forbidding any prieſt, or religious perſon, to appear abroad in a hat without coronets, and enjoining them to keep to the uſe of chaperoons, made of black cloth, with decent coronets; if they were poor, they were at leaſt to have coronets faſtened to their hats, and this upon penalty of ſuſpenſion and excommunication. Indeed, the uſe of hats is ſaid to have been of a longer ſtanding among the eccleſiaſtics of Britanny, by two hundred years, and eſpecially among the canons; but theſe were no other than a kind of caps, and from hence aroſe the ſquare caps worn in colleges, &c.

Lobineau obſerves, that a biſhop of Dol, in the twelfth century, zealous for good order, allowed the canons alone to wear ſuch hats; enjoining, that if any other perſon come with them to church, divine ſervice ſhould immediately be ſuſpended. Tom. i. p. 845.

Hats make a very conſiderable article in commerce: the fineſt, and thoſe moſt valued, are made of pure hair of an amphibious animal, called the caſtor or beaver, frequent in Canada, and other provinces of North America. See BEAVER.

HATS, *Method of making*.—Hats, we have obſerved, are made either of wool, or hair of divers animals, particularly of the caſtor, hare, rabbit, camel, &c. The proceſs is much the ſame in all; for which reaſon we ſhall content ourſelves to inſtance in that of caſtors.

The ſkin of this animal is covered with two kinds of hair; the one long, ſtiff, gloſſy, and pretty thin ſet: this is what renders the ſkin, or fur, of ſo much value: the other is ſhort, thick, and ſoft, which alone is uſed in hats.

To tear off one of theſe kinds of hair, and cut the other, the hatters, or rather the women employed for that purpoſe, make uſe of two knives, a large one, like a ſhoe-maker's knife, for the long hair; and a ſmaller, not unlike a vine-knife, wherewith they ſhave, or ſcrape off, the ſhorter hair.

When the hair is off, they mix the ſtuff: to one-third of dry caſtor putting two-thirds of *old coat*, *i. e.* of hair which has been worn ſome time by the ſavages, and card the whole with cards, like thoſe uſed in the woollen manufactory, only finer; this done, they weigh it, and take more or leſs, according to the ſize or thickneſs of the hat intended. The ſtuff is now laid on the hurdle, which is a ſquare table, parallel to the horizon, having longitudinal chinks cut through it; on this hurdle, with an inſtrument called a *bow*, much like that of a violin, but larger, whoſe ſtring is worked with a little bow-ſtick, and thus made to play on the furs, they fly and mix together, the duſt and filth at the ſame time paſſing through the chinks: this they reckon one of the moſt difficult operations in the whole, on account of the juſtneſs required in the hand to make the ſtuff fall preciſely together, and that it may be every where of the ſame thickneſs. In lieu of a bow, ſome hatters make uſe of a ſieve, or ſearce of hair, through which they paſs the ſtuff.

After this manner they form gores, or two capades, of an oval form, ending in an acute angle at top; and with what ſtuff remains, they ſupply and ſtrengthen them in places where they happen to be ſlenderer than ordinary; though it is to be remembered, that they deſignedly make them thicker in the brim, near the crown, than towards the circumference, or in the crown itſelf.

The capades thus finiſhed, they go on to harden them into cloſer and more conſiſtent flakes by preſſing down a *hardening ſkin* or leather thereon; this done, they are carried to the *baſon*, which is a ſort of bench with an iron plate fitted therein, and a little fire underneath it; upon which laying one of the hardened capades, ſprinkled over with water, and a ſort of mould being applied thereon, the heat of the fire, with the water and preſſing, imbodies the matter into a ſlight hairy ſort of ſtuff, or felt; after which, turning up the edges all round the mould, they lay it by, and thus proceed to the other; this finiſhed, the two next are joined together, ſo as to meet in an angle at the top, and only form one conical cap, after the manner of a manica Hippocratis, or flannel bag.

The hat thus baſoned, they remove it to a large kind of receiver or trough, reſembling a mill-hopper, going ſloping or narrowing down from the edge or rim, to the bottom, which is a copper kettle, filled with water and grounds, kept hot for that purpoſe. On the deſcent or ſloping ſide, called the *plank*, the baſoned hat, being firſt dipped in the kettle, is laid, and here they proceed to work it, by rolling and unrolling it again and again, one part after another, firſt with the hand, and then with a little wooden roller, taking care to dip it from time to time, till at length, by thus full-

ing

ing and thickening it four or five hours, it is reduced to the extent or dimenſions of the hat intended. To ſecure the hands from being injured by this frequent rolling, &c. they uſually guard them with a ſort of thick gloves.

The hat thus wrought, they proceed to give it the proper form, which is done by laying the conical cap on a wooden *block*, of the intended ſize of the crown of the hat, and thus tying it round with a packthread, called a *commander*: after which, with a piece of iron or copper bent for that purpoſe, and called a *ſtamper*, they gradually beat or drive down the commander all round, till it has reached the bottom of the block, and thus is the crown formed; what remains at bottom, below the ſtring, being the brim.

The hat being now ſet to dry, they proceed to *ſinge* it, by holding it over a flare of ſtraw, or the like: then it is *pounced*, or rubbed over with pumice, to take off the coarſer knap; then rubbed over afreſh with ſeal-ſkin to lay the knap a little finer; and laſtly, carded with a fine card to raiſe the fine cotton, with which the hat is afterwards to appear.

Things thus far advanced, the hat is ſet upon its block, and tied about with a packthread as before, to be dyed. The dyer's copper is uſually very large, holding ten or twelve dozen of hats. The dye, or tincture, is made of logwood, verdigris, copperas, and alder-bark; to which ſome add galls and ſumac.

In the manufacture of La Cote d'Or, ſays citizen Chauſſier, (Journal Polytechnique, i. p. 160, &c.) the nut-gall is not uſed, and oak-bark has been ſubſtituted with advantage.

Here the hat is kept boiling for about three quarters of an hour; then taken out and ſet to cool, and then returned to the dye, and this for ten or twelve times ſucceſſively. For the method of dyeing hats, ſee DYEING *of Hats*.

The dye being complete, the hat is returned to the hatter, who proceeds to dry it, by hanging it in the top or roof of a ſtove or oven, at the bottom of which is a charcoal fire; when dry, it is to be ſtiffened, which is done with melted glue or gum ſenegal, applied thereon by firſt ſmearing it, and beating it over with a bruſh, and then rubbing it with the hand. The next thing is to *ſteam* it on the *ſteaming baſon*, which is a little hearth or fire-place, raiſed three feet high with an iron plate laid over it exactly covering the hearth; on this plate they firſt ſpread cloths, which being ſprinkled over with water to ſecure the hat from burning, the hat is placed brim downwards thereon; when moderately hot, the workman ſtrikes gently on the brim with the flat of his hand, to make the joinings incorporate and bind ſo as not to appear; turning it from time to time, this way and that way, and at laſt overturning and ſetting it in the crown.

When ſteamed ſufficiently and dried, they put it again on the block, and bruſh and *iron* it on a table or bench for the purpoſe, called the *ſtall-board*; this they perform with a ſort of irons like thoſe commonly uſed in ironing linen, and heated like them, which being rubbed over and over each part of the hat, with the aſſiſtance of the bruſh, ſmoothens and gives it a gloſs, which is the laſt operation; nothing now remaining but to clip the edges even with ſciſſars, and ſew a lining to the crown.

The ſeveral operations employed in hat-making, are ſeparately deſcribed under the articles FELTING, FULLING, and DYEING, to which the reader is referred. The laſt operation, ſays Chauſſier, (ubi ſupra), conſiſts in lining the inner ſurface of the crown, as well as of the brim of the hat, with a glutinous ſubſtance, which in drying gives firmneſs to the work, and preſerves its form. The uſual compoſition is made of gum arabic, common gum, and Flanders glue, which are diſſolved together in a ſufficient quantity of water, and brought to the requiſite thickneſs by boiling. This preparation, ſimple and eaſy as it appears, is not indifferent with regard to the beauty and duration of the work. If it be too tenacious, it renders the ſtuff dry and brittle, and after ſome months uſe, a kind of greyiſh incruſtation is formed on the ſurface, which alters the texture. "It appeared to me, (ſays Chauſſier), that this effect was cauſed by the gum arabic which is added to the glue. I therefore ſought among the plants of our own country for a ſimple preparation, which might be ſubſtituted inſtead of theſe natural and friable gums. The mucilaginous principle abounds in a great number of plants, and may be eaſily extracted by ebullition; and a gum may even be formed by evaporation, which preſerves its ſuppleneſs and flexibility. Theſe conſiderations induced me to recommend, inſtead of the uſual preparation, a ſolution of glue in a decoction loaded with the mucilage of linſeed oil. This preparation has been long uſed with economy in the manufactory, and with advantage in the excellence of the work. Since that time citizen Margueron having communicated to me his obſervations on the mucilage which may be extracted from the leaves of the horſe-cheſnut tree (*maſronier d'Inde*), and having aſcertained how great a portion of mucous and adheſive matter theſe leaves afford, eſpecially when the foliation is in its vigour; a ſtrong decoction of theſe leaves has been uſed with much ſucceſs to make the preparation with glue." Our author adds, that there are many other native plants which would be equally proper to afford factitious gums, and of which the uſe would be very advantageous.

HATS, *Laws relating to*. By 24 Geo. III. c. 51, all retailers of hats, commonly called felt or wool, ſtuff or beaver hats, or any leather or japanned hats, ſhall take out a licence from the ſtamp-offices, for which ſhall be paid within the bills, 40*s*., elſewhere 5*s*.; which licence ſhall be renewed annually, ten days before the end of the year. If any retailer ſhall ſell any felt hats without a licence, he ſhall forfeit 50*l*.; and every perſon who ſhall ſell any leſs quantity than one dozen of hats at one time to any one perſon, ſhall be deemed a retailer. Such perſon ſhall put over his door, or in the front of his houſe or ſhop, the words "dealer in hats by retail," on pain of forfeiting 40*s*.; and if an unlicenſed perſon put up theſe words, he ſhall forfeit 50*l*. For every hat ſold by a licenſed retailer ſhall be paid the following duty: *viz*. if not exceeding the value of 4*s*., 3*d*.; above 4*s*. and not exceeding 7*s*., 6*d*.; from 7*s*. to 12*s*., 1*s*.; and above 12*s*., 2*s*. By 36 Geo III. c. 125, all hats, previous to the delivery of them, ſhall be ſtamped on the lining; however, any licenſed dealer may ſell to another of the ſame deſcription any unſtamped hats. The penalty for ſelling unſtamped hats is 10*l*.; and for fixing ſtamped linings after they have been uſed, there is a penalty of 10*l*. and the ſame penalty alſo for receiving or ſelling hats unſtamped. Counterfeiting or forging of ſtamps is a capital felony. By 43 Geo. III. c. 68, for every hat, as above deſcribed, imported, ſhall be paid a duty of 1*l*. 1*s*., and on exportation ſhall be allowed a drawback of 10*s*. 6*d*. For the encouragement of the hat-manufacture, it is enacted by 24 Geo. III. c. 21. that no hare or coney ſkins ſhall be exported on the penalty of 500*l*. and forfeiture of the ſame; and every perſon aſſiſting ſhall forfeit 40*l*. Dyeing ſuch ſkins incurs a forfeiture of the ſame, and of 20*l*. For the further encouragement of the hat-manufacture, all goats' hair or Turkey goats' wool may be imported duty free.

HATS for women have been made in various forms, of ſilk, ſtraw, ſhavings of wood, ivory, feathers, gold, and ſilver.

HAT

HAT is alſo figuratively uſed for the dignity of a cardinal, or a promotion to that dignity. In this ſenſe they ſay, to expect a hat; to claim, or have pretenſion to the hat, &c.

Pope Innocent IV. firſt made the hat the ſymbol or cognizance of the cardinals; enjoining them to wear a red hat, at all ceremonies and proceſſions, as a token of being ready to ſpill their blood for Jeſus Chriſt. See CARDINAL.

HAT, in *Heraldry*. See CHAPEAU.

HATBOROUGH, or HATFIELD, in *Geography*, a town of America, in Montgomery county, Pennſylvania, on the N. E. ſide of Pannepack creek, containing a library of more than 1000 volumes, and 520 inhabitants.

HATCH, in *Engineery*, is a moveable board for penning or letting off water, otherwiſe a paddle, ſluice, &c.

HATCH, in *Mining*, or pie, knot, &c. denotes the meeting or croſſing of two veins of ore, which is uſually rich in ſuch places.

HATCH, in *Rural Economy*, a term ſignifying a brood of any ſort of oviparous birds, ſuch as hens, ducks, geeſe, turkeys, &c. See POULTRY.

HATCHEL, or HITCHEL, in the *Manufactory of Flax, Hemp, &c.* a tool not unlike a card, for dreſſing and combing them into fine hairs. See CARD.

They conſiſt of ſharp-pointed iron pins, or teeth, ſet orderly in a board.

Of theſe there are ſeveral ſorts, ſome with finer and ſhorter teeth, others with them coarſer and longer.

HATCHES, in a *Ship*, a ſort of trap-doors in the midſhip, or between the main-maſt and fore-maſt, through which goods of bulk are let down into the hold. There are ſeveral of theſe ſquare or oblong paſſages in the deck of a ſhip, leading from one deck to another, and into the hold or lower apartments. Hence, the

HATCH-*way* is that place where hatches are.

To lay any thing in the hatch-way, is to put it ſo that the hatches cannot be come at, or opened.

HATCHES, *Coamings of the*. See COAMINGS.

HATCHES are alſo flood-gates, ſet in a river, &c. to ſtop the current of water.

The word is particularly uſed for certain dams or mounds, made of rubbiſh, clay or earth, to prevent the water that iſſues from the ſtream-works, and tin-waſhes in Cornwall, from running into the freſh rivers.

The tenants of Bulyſtoke, and other manors, are bound to do certain days work to the hatches.

HATCHES, in *Mining*, a term uſed in Cornwall, to expreſs any of the openings of the earth, either in mines, or in ſearch of them; the fruitleſs openings are called eſſay hatches; the real mouths of the veins, tin-hatches; and the places where they wind up the buckets of the ore, wind-hatches.

HATCHET, an inſtrument wherewith to hew wood. The hatchet is a ſmaller, lighter ſort of ax, with a baſil edge on its left ſide; having a ſhort handle, as being to be uſed with one hand.

HATCHET, a ſmall ax, uſed by the pioneers, who go before to prepare the ways for an army, by cutting down hedges, buſhes, ſtyles, or gates. The grenadiers carry ſometimes each a hatchet by his ſide; and the French dragoons, who have but one piſtol, have a hatchet hanging at their ſaddle-bows on the right ſide.

HATCHET *vetch*, in *Botany*. See CORONILLA and BISERRULA.

HATCHET-*ſhaped Leaf, folium dolabriforme*, a ſucculent leaf of a form ſcarcely ſeen but in *Meſembryanthemum dolabriforme*, Curt. Mag. t 32. See LEAF.

HATCHING, the act whereby fecundated eggs, after ſeaſonable incubation, exclude their young.

Hatching, with reſpect to the oviparous tribe, amounts to the ſame as parturition, or delivery, in the viviparous. In Egypt they formerly hatched all their chickens by the heat of an oven: the method whereof is given us by Mr. Greaves, in the Philoſophical Tranſactions, N 117, or Abridgment, vol. ii. p. 851, &c. This practice of hatching eggs without incubation, is ſaid by the Egyptians to proceed from the experience, that, at a certain ſeaſon, the eggs foſtered only by the hens are commonly unprolific; whereas of thoſe hatched in the ovens, not quite one-third is loſt. This art, ſays Niebuhr, ("Travels in Arabia, &c." p. 92. Eng. ed.) is much neglected at preſent by the Egyptians, who probably did not derive from it all the advantage which they expected. Unleſs at Cairo, he ſays, there are no furnaces for this purpoſe; theſe belong to the Pacha. They are uſed only in ſummer; for the hatching, it is ſaid, does not ſucceed ſo well in winter. Private perſons indeed carry ſome eggs to the furnaces, and pay ſo much per hundred, to a perſon who undertakes the management of hatching them. The owners mark their eggs; and the hatcher is obliged to ſhew the marks upon thoſe which fail in the hatching. But according to this traveller's account, the number of chickens hatched in this way is not very conſiderable.

They have houſes built for the purpoſe, having a long entrance, on each ſide whereof are twelve or fourteen ovens, whoſe bottoms and ſides are formed of ſun-dried bricks, lined with mats for the eggs to lie on, and the tops covered with ſticks, except two ſpaces, which are brick, and ſerve as hearths to build the fires on wherewith the eggs are to be heated; over theſe is another ſtory of ovens, having holes, which are either ſtopped with tow, or left open at pleaſure, to govern the heat of the ovens below.

They begin to heat the ovens in the middle of January, ſpending on them every morning about a hundred pounds weight of camels' or buffalos' dung, and the like quantity at night, till the middle of February; by which time the ovens are too hot for the hand to be held to the walls. After this they put in the eggs to hatch, which they continue ſucceſſively to the end of May.

The eggs are firſt put upon the matts in the lower ovens, upon the ground, 7 or 8000 eggs in number, and laid only double one upon another: in the ovens over theſe, the fire is made in the little channels, from whence the heat is conveyed into the lower; the eggs directly under theſe hearths lie threefold.

At night when they new-make their fires in their hearths, they remove the eggs that were directly undermoſt, laying three upon one another, in the place of thoſe which lay on the ſides only double; and theſe being now removed, they lie treble under the hearth, becauſe the heat is greater there than on the ſides.

Theſe eggs continue in the lower ovens fourteen days and nights; after which they remove them into the upper; and in theſe, there being no more fire uſed, they turn the eggs four times every twenty-four hours. Mr. Browns ſays, (in his "Travels in Africa," p. 77.) that the eggs are placed on each row of ſhelves in ſuch a manner as not to touch each other; and that they are moved five or ſix times in every 24 hours. He adds, the ovens where theſe eggs are placed are of the moſt ſimple conſtruction, conſiſting only of a low arched apartment of clay, in which are formed two rows of ſhelves, and that all poſſible care is taken to diffuſe the heat equally throughout,

throughout, and there is but one broad aperture, large enough to admit a man ſtooping. At the end of the firſt eight days, he ſays, it is known which eggs will not be productive.

The 21ſt, or 22d day the chickens are hatched, which the firſt day do not eat; the ſecond day they are fetched away by women who give them corn, &c. The maſter of the ovens hath a third part of the eggs for his coſt and pains, out of which he is to make good to the owners (who have two-thirds in chickens for their eggs) if any happen to be ſpoiled or miſcarry.

The fire in the upper ovens, when the eggs are placed in the lower, is thus proportioned: the firſt day there is the greateſt fire, the ſecond leſs than the firſt; the fourth more than the third, the fifth leſs; the ſixth more than the fifth, the ſeventh leſs: the eighth more, the ninth without fire; the tenth a little fire in the morning; the eleventh they ſhut all the holes with flax, &c. making no more fire; for if they ſhould, the eggs would break. They take care that the eggs be not hotter than the eye of a man, when they are laid upon it, can well endure. When the chickens are hatched, they put them into the lower ovens.

The number of theſe ovens in different parts of the country, which are attended by the inhabitants of a village called Bermè, is about 386, and they uſually keep them at work for ſix months; as, therefore, each brood is perfected in twenty-one days, it is eaſy in every one of them to hatch eight different broods of chickens. If we ſuppoſe that only two-thirds of the eggs are hatched, and each brood conſiſts of at leaſt 30,000 chickens, the ovens of Egypt are capable of producing, yearly, at leaſt 9,264,0000 chickens.

Mr. Reaumur has diſcovered, that the heat neceſſary for this purpoſe, is nearly the ſame with that marked 32 upon his thermometer, or that marked 96 on Fahrenheit's. If, therefore, theſe eggs be kept in this degree of heat, they will as certainly hatch, as if the parent hen had ſat upon them; and indeed it is impoſſible it ſhould be otherwiſe, ſince this heat anſwers nearly to that of the ſkin of the hen, or even of mankind; ſo that the empreſs Livia, as Pliny relates, might truly hatch a chicken in her boſom, if ſhe had but the patience to keep an egg there for the ſame number of days that it ought to have continued under a hen.

After many experiments Mr. Reaumur found, that ſtoves heated by means of a baker's oven, ſucceeded equally well with thoſe made hot with layers of dung. The furnaces of glaſs-houſes, and thoſe of the melters of metals, might no doubt be made to anſwer the ſame purpoſe: if, therefore, an eaſy method could be found to regulate the heat of the ſtove, it would be extremely convenient for bakers or paſtry-cooks to hatch, with little or no expence, a very great number of chickens, which they might diſpoſe of to the country people, to be reared till marketable. Should a thermometer be judged neceſſary for this purpoſe, it will be ſufficient to mark on it only ſuch degrees as are abſolutely neceſſary; by which means the inſtrument will not only come cheaper, but be more readily underſtood by the ignorant people, for whoſe uſe it is deſigned.

Such an inſtrument however may be wholly diſpenſed with; a lump of butter, of the ſize of a walnut, melted with half as much tallow, ſerving to indicate the heat of the ſtove with ſufficient exactneſs; when the heat is too great, this mixture, which is kept in a phial, will become as liquid as oil; and when the heat is too ſmall, it will remain fixed in a lump; but it will flow like thick ſyrup, upon inclining the bottle, if the ſtove be of a right temper: great attention therefore ſhould be given to keep the heat always at this degree, by letting in freſh air, if it be too great, or ſhutting the ſtove more cloſe, if it be too ſmall.

But this is not all. That all the eggs in the ſtove may equally ſhare the irregularities of the heat, it will be neceſſary to ſhift them from the ſides to the centre, and *vice verſâ*: thereby imitating what the hens themſelves do by thoſe upon which they ſit; for hens are frequently ſeen to make uſe of their bills to puſh to the outer parts thoſe eggs which were neareſt to the middle part of their neſt, and to bring into that middle part ſuch as before lay neareſt to the ſides of the ſame.

As to the form of the ſtoves, no great nicety is neceſſary; a chamber over an oven will do very well, only in order to aſcertain the due degree of heat, it will be neceſſary to have phials of butter, as directed above, in ſeveral parts of the rooms; and when the heat wants to be either increaſed or diminiſhed, it is ſufficient to diminiſh or increaſe the communication between the air in the room and that abroad, by opening or ſhutting ſome of the openings made in the wall for that purpoſe.

In order to cheriſh the new-hatched chickens, capons may be taught to tend them in the ſame manner as hens do. Mr. Reaumur tells us, that he has ſeen above two hundred chickens at once, all led about and defended by only three or four ſuch capons, which clucked like hens, to call in the chickens that had ſtrayed too far off; and even redoubled their call, when they found any nice bits, to invite the young brood to come and pick them up: nay cocks may be taught to do the ſame office, which they as well as capons will continue to do all their lives afterwards. But Mr. Reaumur, not ſatisfied with the aſſiſtance he could procure from cocks and capons, has invented a ſort of low boxes without bottoms, and lined with furs; theſe, which he calls artificial parents, not only ſhelter the chickens from the injuries of the air, but afford a kindly warmth, ſo that they preſently grow fond of them, and take the benefit of their ſhelter as readily as they would have done under the wings of a hen.

For a few weeks after hatching, it will be neceſſary to keep the chickens in a room artificially heated, and furniſhed with theſe boxes; but afterwards they may be ſafely expoſed to the air in the court-yard, in which it may not be amiſs to place one of theſe artificial parents to ſhelter them, ſhould there be any occaſion.

As to the manner of feeding the young brood, they are generally a whole day after being hatched, before they take any food at all; and then a few crumbs of bread may be given them for a day or two, or millet ſeed mixed with the crumbs; after which they will begin to pick up inſects and graſs for themſelves.

People in the country, who have plenty of conveniences for the raiſing of poultry, will hardly give themſelves the trouble to hatch chickens in this artificial manner. It is in villages near great towns, and principally in the neighbourhood of the capital city, that it would be of the greateſt importance to promote the eſtabliſhment of this kind of ſtoves. Vide Mr. Trembley's Abſtract of the Art of Hatching domeſtic Fowls, tranſlated from the original Treatiſe of M. Reaumur, where he explains every difficulty.

HATCHING, or *Haching*, in *Deſigning and Engraving*, ſignifies the making of lines with a pen, pencil, graver, or the like; and interſecting, or going acroſs thoſe lines, with others drawn over them another way.

The depths and ſhadows of draughts are uſually formed by hatching or hatch-work. See ENGRAVING and ETCHING.

HATCHING, among *Miners*, See DIGGING.

HATCHING, or *Claking*, is applied to any wall or bank

of

of earth, or puddle-gutter, when it is not upright but overhangs in one direction.

HATCHINGS are of great uſe in *Heraldry*, to diſtinguiſh the ſeveral colours of an eſcutcheon, without its being illuminated.

The firſt kind of hatching in pale, or from top to bottom, ſignifies *gules*, or *red:* the ſecond is feſs, acroſs the coat, *azure*, or *blue*.

Hatching in pale, counter-hatched in feſs, ſignifies *ſable*, or *black*. Hatching in bend, proceeding from right to left, ſignifies *green;* and that in bars, from left to right, *purple*.

When the coat is only dotted, it is ſuppoſed to be *or*, or *gold;* and when quite bare or void, *argent*, or *white*.

This invention is commonly aſcribed to F. Pietra Sancta; though the Sieur de la Columbiere has diſputed his title to it.

HATCHMENT, the marſhalling of ſeveral coats of arms in an eſcutcheon.

HATCHMENT is alſo a popular name for an *atchievement*. Atchievement, in a general ſenſe, denotes the arms, creſts, and ſupporters, which a perſon has a lawful right to bear, with all the exterior ornaments, as helmet, mantle, motto, &c.

By theſe hatchments, or funeral eſcutcheons, it may be known after any perſon's deceaſe, what rank either he or ſhe held when living; and if it be a gentleman's hatchment, whether he was a bachelor, married man, or widower, with the like diſtinctions for gentlewomen. In the hatchment, (*Plate Heraldry, Hatchments, fig.* 1.) are repreſented the arms of a private gentleman and his wife parted per pale, the dexter ſide, which is *gules, three bars or*, for the huſband; having the ground without the eſcutcheon black, which denotes the man to be dead; and the ground on the ſiniſter ſide being white ſignifies that the wife is living. When a married gentlewoman dies firſt, the hatchment is diſtinguiſhed by a contrary colour from the former; that is, the arms on the ſiniſter ſide have the ground without the eſcutcheon black, whereas thoſe on the dexter ſide, for her ſurviving huſband, are upon a white ground: beſides, the hatchment of a gentlewoman is differenced by a cherub over the arms inſtead of a creſt. (See *fig.* 2.) When a bachelor dies, his arms may be depicted ſingle, or quartered, with a creſt over them, but never impaled as the others are; and the whole ground without the eſcutcheon is black. (See *fig.* 3.) When a maid dies, her arms, which are placed in a lozenge, may be ſingle or quartered, have the whole ground black, and inſtead of a creſt have a cherub over them. (See *fig.* 4.) When a widower dies, his arms are repreſented impaled with thoſe of his deceaſed wife, having a helmet, mantling, and creſt over them, and the whole ground without the eſcutcheon black. (See *fig.* 5.) When a widow dies, her arms are impaled with thoſe of her deceaſed huſband, but incloſed in a lozenge; over them is placed a cherub inſtead of a creſt, and the whole ground without the eſcutcheon is black. (See *fig.* 6.) If a widower or bachelor ſhould be the laſt of his family, the hatchment is depicted as in *fig.* 7, and that of a maid or widow, whoſe family is extinct by her death, is depicted as in *fig.* 8. having a death-head generally annexed to each hatchment, denoting, that death has conquered all. The ſame rules are obſerved with reſpect to the eſcutcheons placed on the hearſe and horſes uſed in pompous funerals, except that they are not ſurmounted with creſts, but always plain; however, herald-painters commonly enſign thoſe of peers with coronets, and that of a maiden lady with a knot of ribbands. Porny's El. of Her. p. 240, &c.

HATCHY, in *Geography*, a navigable river of America, in the ſtate of Teneſſee, which runs weſterly into the Miſſiſippi, about 19 miles N. of Wolf river, N. lat. 35 5'. W. long. 70° 28', and is about 80 yards wider ſeven miles from its mouth.

HATDER, a town of Aſiatic Turkey, in the government of Moſul; 20 miles N. W. of Teerit.

HATFIELD, a pariſh in the wapentake of Strafforth and Tickill, in the Weſt Riding of the county of York, England, contains 290 houſes, and 1301 inhabitants. Here is a large church, the living annexed to which is a perpetual curacy. This place is particularly noticed in the agricultural report of the county, for its large chace, which contains about 180,000 acres of land; nearly one-half of which was formerly a moraſs. In the reign of king Charles I. ſir Cornelius Vermuyden, having drained it, brought the greater part into a ſtate of profitable cultivation. For this purpoſe he is ſaid to have expended nearly 400,000*l.* About 5000 acres of this land are appropriated as common for the benefit of the neighbouring inhabitants. On a ſmall iſland in the midſt of this moraſs formerly lived William of Lindholme, a noted hermit, whoſe cell, and other memorials of him, were ſtanding here in the year 1747. Near the village are ſeveral remains of entrenchments. This place is about three miles from Thorn, and 167 north of London.

HATFIELD, or *Biſhops' Hatfield*, a market town in the hundred of Broadwater, Hertfordſhire, England, was, in the Saxon times, called Haethfeld, from its ſituation on a heath, and was an ancient demeſne of the Saxon kings, till Edgar, in the tenth century, granted it to the abbey at Ely, in Cambridgeſhire. On the converſion of that foundation into a biſhopric, in the reign of Henry I., it became attached to the new ſee; and the manor-houſe becoming a palace of the biſhops, the town was thenceforth diſtinguiſhed by the appellation of Biſhops'-Hatfield. Queen Elizabeth, who had reſided in the biſhop's palace ſome years previous to her acceſſion to the throne, greatly admired the ſituation; and by virtue of a ſtatute, which gave her the power of exchange, procured the alienation of this manor from the then biſhop of Ely, Richard Cox. James I., in the third year of his reign, exchanged it for the houſe, manor, and park of Theobalds, with his miniſter Robert Cecil, earl of Saliſbury. Hatfield church, a handſome fabric, conſiſts of a nave, chancel, aiſles, and embattled tower, with a chapel, or burial-place, of the earls of Saliſbury, on the north ſide of the chancel. This chapel was erected by Robert Cecil, the firſt earl of Saliſbury of that name, but contains neither monumental inſcription, nor other memorial, for any of the family, except the founder, who is repreſented in his robes, lying on a ſlab of black marble. On the ſouth ſide of the chancel is the chapel of the lords of the manor of Ponſburne, and in this are ſeveral monuments of the Brookets and Reads of Brooket-hall. Hatfield is 20 miles diſtant from London; has a market on Thurſdays, and two annual fairs. The population, as returned under the act of 1800, amounted to 2442, the number of houſes to 482.

Hatfield houſe, the principal reſidence of James Cecil, marquis of Saliſbury, occupies a beautiful ſituation in a finely diverſified park. This manſion, which is of brick, and of great extent, was erected by earl Robert, when the manor came into his poſſeſſion, by exchange with king James. Many of the apartments are large, and decorated with pictures of conſiderable merit. Chauncey's Hiſtory and Antiquities of Hertfordſhire, one vol. folio.

HATFIELD REGIS, or *Hatfield Broad Oak*, a pariſh in the hundred of Harlow, and county of Eſſex, England, was formerly a conſiderable market town, but is now only a ſcattered

ſcattered village with very little trade. It was anciently part of the king's demeſne, whence it derived the name of Regis; as it did that of Broad-Oak, or Brad-Oak, from an oak of extraordinary ſize, ſuppoſed to have flouriſhed here in the Saxon era. In the church, a very ancient ſtructure, is the mutilated effigy, carved in wood, of Robert de Vere, third earl of Oxford, who was buried here in 1221. Near the eaſt end of the church, on a ſpot now converted into gardens, ſtood a Benedictine priory, founded about the year 1135, by Aubrey de Vere, father of the firſt earl of Oxford. After the diſſolution, the ſcite and revenues were purchaſed by Thomas Barrington, eſq., whoſe family were ſettled at Barrington-hall, in this pariſh, about a mile and a half north from the church, as early as the reign of Henry I. From this manſion, great part of which has been pulled down, and the remainder converted to a farm houſe, the Barringtons removed to the priory, where they reſided till the beginning of the laſt century, when it was taken down. The preſent Barrington-hall, a ſpacious brick manſion, at a little diſtance north from the ſcite of the priory, was erected by John Barrington Shales, eſq. The pariſh of Hatfield, which is diſtant 26 miles from London, was returned in the year 1801, as containing 271 houſes, inhabited by 1436 perſons. Morant's Hiſtory and Antiquities of Eſſex, two volumes folio.

HATFIELD, a pleaſant town of America, in Hampſhire county, Maſſachuſetts, on the W. bank of an iſland of Connecticut river; 5 miles N. of Northampton, and 100 W. of Boſton; containing 103 houſes, and 809 inhabitants.

HATHERLEIGH, an ancient market and borough town in the hundred of Black Torrington, in the county of Devon, England, is a ſmall inconſiderable place, ſituated on a branch of the river Torridge, near its confluence with the Oke. The houſes are principally built with red earth, and thatched, and have a very mean appearance. The manor anciently belonged to the abbey of Taviſtock; by one of whoſe abbots, a large plot of common land was given about four hundred years ago, for the advantage of this borough. The town is governed by a portreeve and two conſtables, with other inferior officers, choſen annually at the court held by the lord of the manor. Though it bears the title of borough, Hatherleigh does not poſſeſs the privilege of ſending members to parliament. It is ſituated 200 miles diſtant from London, in a fertile neighbourhood; has a market on Fridays, and four yearly fairs, beſides a large annual cattle-market. The inhabitants are principally employed in agriculture, and the woollen manufacture: their number, as returned under the act of parliament of 1801, was 1218; that of houſes 219. Hiſtory of Devon, three vols. folio.

HATLEVEN, a ſmall iſland in the North ſea, near the coaſt of Norway. N. lat. 61° 20'.

HATLEY, a townſhip in Lower Canada, in which is lake Tomefobi, containing about 300 inhabitants.

HATTAN, a ſmall iſland on the W. ſide of the gulf of Bothnia. N. lat. 61 37. E. long. 17 30'.

HATTEM, a town of Holland, in the province of Guelderland, ſituated on the Iſſel; 13 miles N. of Deventer.

HATTEMISTS, in *Eccleſiaſtical Hiſtory*, the name of a modern Dutch ſect, ſo called from Pontian Van Hattem, a miniſter in the province of Zealand, towards the cloſe of the 17th century, who being addicted to the ſentiments of Spinoſa, was on that account degraded from his paſtoral office. The Verſchoriſts and Hattemiſts reſemble each other in their religious ſyſtems, though they never ſo entirely agreed as to form one communion. The founders of theſe ſects deduced from the doctrine of abſolute decrees, a ſyſtem of fatal and uncontroulable neceſſity; they denied the difference between moral good and evil, and the corruption of human nature; from hence they farther concluded, that mankind were under no ſort of obligation to correct their manners, to improve their minds, or to obey the divine laws; that the whole of religion conſiſted not in acting but in ſuffering; and that all the precepts of Jeſus Chriſt are reducible to this one, that we bear with cheerfulneſs and patience the events that happen to us through the divine will, and make it our conſtant and only ſtudy to maintain a permanent tranquillity of mind. Thus far they agreed; but the Hattemiſts farther affirmed, that Chriſt made no expiation for the ſins of men by his death, but had only ſuggeſted to us by his mediation, that there was nothing in us that could offend the deity; this, they ſay, was Chriſt's manner of juſtifying his ſervants, and preſenting them blameleſs before the tribunal of God. It was one of their diſtinguiſhed tenets, that God does not puniſh men for their ſins, but by their ſins. Theſe two ſects, ſays Moſheim, ſtill ſubſiſt, though they no longer bear the names of their founders. Moſh. Eccl. Hiſt. vol. iv.

HATTENHEIM, in *Geography*, a town of Germany, in the circle of the Lower Rhine, on the Rhine; 12 miles W. of Mentz.

HATTERAS, a very dangerous cape, on the coaſt of North America, extending far into the ocean from the coaſt of North Carolina, in N. lat. 35° 15'. During half the year it is remarkable for ſudden ſqualls of wind, and for very violent ſtorms of thunder, lightning, and rain.

HATTIAH, an iſland of Bengal, in the mouth of the Ganges, about 14 miles long, and 8 broad. N. lat. 22 34'. E. long. 91'.

HATTINGEN, a town of Germany, in the county of Mark; 16 miles N.E. of Duſſeldorp. N. lat. 51° 18'. E long. 7 8.

HATTOCK, in *Rural Economy*, the common name of a ſtouk or ſhock of grain in ſome places, which is conſtituted of ſix, eight, ten, or twelve ſheaves, ſet up together in ſuch a manner, as to be capable of being protected, in ſome meaſure, from the effects of wet ſeaſons, by means of covering ſheaves. In this intention, two ſheaves are generally employed, which are denominated hooders, and which are opened in the middle and ſlid over the ſtandards, having their butt ends meeting at the top. In this way, they are as it were thatched. The method is common where grain is reaped by the ſickle, and ſometimes in all other caſes. See STOUK.

HATTUNUDDA, in *Geography*, a town of Hindooſtan, in Oriſſa; 32 miles S.E. of Boad.

HATVANY, a town of Hungary; 20 miles N.E. of Buda.

HATUN, a town of Peru, in the dioceſe of Cuſco; 85 miles S. of Cuſco.

HATZFELD, a town of Germany, in the principality of Upper Heſſe; 36 miles S.W. of Caſſel. N. lat. 50 59'. E. long. 8 36'.

HAVA, a town on the S. coaſt of the iſland of Ceram. S. lat. 3° 18'. E. long. 129° 48'.

HAVANNAH, a city and ſea-port on the N. coaſt of the iſland of Cuba, in the Weſt Indies, founded by Diego Velaſquez, who conquered the iſland at the commencement of the ſixteenth century. The harbour is very highly extolled, and is capable of containing 1000 ſhips, without cable or anchor, as there are generally ſix fathoms of water in the bay; and it is ſtrongly fortified by nature and art. Its entrance

Straban and Preſton,
New-ſtreet Square, London.

trance is a narrow channel of difficult acceſs, and guarded by platforms, various works, and artillery, for half a mile, which is the length of the paſſage. The mouth of the channel is ſecured by two ſtrong forts, one on the E. ſide called "Moro" fort, of a triangular form, fortified with baſtions, and 40 pieces of cannon, almoſt level with the water, and the other on the oppoſite ſide, called the "Puntal," joining to the town, which is ſituated to the weſtward of the entrance of the harbour, and ſurrounded by ramparts, baſtions, and ditches. It has likewiſe other forts and platforms, which render it almoſt invincible. In this harbour all the ſhips that come from the Spaniſh ſettlements, and formerly the galeons and flota, aſſemble on their voyage to Spain; and on this account Havannah is the richeſt and the moſt populous town poſſeſſed by the Spaniards in their Weſt India iſlands. It contains 11 handſome, and richly ornamented churches, two hoſpitals, and other public buildings, and, as it is ſaid, more than 2000 houſes. Its juriſdiction extends to half the iſland, and the other half belongs to St. Jago, which has been uſually reckoned the capital. On account of the great reſort of perſons to this town in the courſe of navigation and commerce, and alſo the indolence of the Spaniards in cultivating the ſoil of the iſland, proviſions are ſometimes ſcarce, and always dear. This town was taken by the Buccaneers under Capt. Morgan in 1669, and by the Engliſh under lord Albemarle and ſir George Pocock in 1762, fort Moro having been taken by ſtorm; but reſtored at the peace of Paris in 1763. N. lat. 23° 12'. W. long. 82° 14'.

HAVANT, a market-town and pariſh in the hundred of Boſmere, in the Portſdown diviſion of the county of Hants, England, is ſituated near the borders of Suſſex, and oppoſite the iſle of Hayling. It conſiſts principally of one long ſtreet, interſected by another at right angles. The number of houſes, as returned under the act of 1800, was 345; that of inhabitants 1670. The church ſtands in the centre of the town: it is built in the form of a croſs, with a tower ariſing from the interſection; and diſplays various ſpecimens of architecture of the ſtyle of very different periods. A market was granted to Havant by king John, probably through the interceſſion of the monks of Wincheſter, to whom the manor was given by Ethelred. This market is held on Saturdays, and is well ſupplied with all kinds of grain. Here are two annual fairs. This town experienced two ſhocks of an earthquake, October 25, 1734, each continuing two or three minutes; a great alarm was occaſioned, but no damage enſued. Havant is diſtant from London 66 miles.

About a mile diſtant from Havant are the ruins of Warblington caſtle. It appears to have been originally a ſquare pile, of about 200 feet, ſurrounding a quadrangular court: but the only part now ſtanding is the tower-gateway; and even this is verging to decay. The whole was ſurrounded by a foſſe, about ten feet deep, and including about an acre of ground. Before the northern angle appears to have been a ſort of entrenched camp, of five acres, now overgrown with wood, ſurrounded by a bank nearly eight feet high, and a ditch of a ſimilar depth to that round the caſtle. Warner's Collections for Hampſhire, ſix vols. 4to.

HAUARA, a town of Egypt; 8 miles S.E. of Fayoum.

HAVASH, or HAWASCH, a river of Abyſſinia, which runs into the Arabian ſea. N. lat. 19°. E. long. 44° 55'.

HAUBERGETUM, in our *Old Writers*, the ſame with *halſberga* and *habergeon*, which all ſignify a coat of mail.

HAUBO, in *Geography*, a town of Sweden, in Weſt Gothland; 7 miles N.N.W. of Gotheborg.

HAUBOURDIN, a town of France, in the department of the North, and chief place of a canton in the diſtrict of Lille; 3 miles S.W. of it. The place contains 1809, and the canton 13,634 inhabitants, on a territory of 67½ kiliometres, in 15 communes.

HAUD, a town of Arabia, in the province of Yemen; 56 miles S. of Sàade.

HAUDIMONT, *the abbé* S. P. MEUNIER D', in *Biography*, a compoſer of Latin motets in the ancient church ſtyle, that were long performed at the Concert Spirituel at Paris with great applauſe, was a native of Burgundy, and of a noble family, ruined by Law's Miſſiſippi ſyſtem. The abbé was educated at Dijon, which he quitted at the age of 24, and was glad to accept of the chapel-maſter's place at Chalons-ſur-Saône, where he remained ſix years. From Chalons he went to the capital, ſeriouſly to apply himſelf to compoſition; where he became the diſciple and friend of the celebrated Rameau, his countryman.

In Auguſt 1764, the chapel-maſter of the Holy Innocents having died ſuddenly, he was appointed his ſucceſſor. It was then that he compoſed the chief part of the motets, which were ſo often heard at the concert ſpirituel, in the king's chapel, and on public feſtivals.

M. Laborde, in his "Eſſais ſur la Muſique," whence we have this article, laments that "the abbé Haudimont is only admired by the very ſmall number of lovers and preſervers of true muſic (meaning that of Lulli and Rameau,) ſo much depreciated by thoſe who are ignorant of its principles, and who find it eaſier to abuſe than to perform it. But their ſpleen is exerciſed in vain: taſtes are tranſient, and ſoon forgotten, and ſoon or late the true taſte returns; though its return is not very rapid, in muſic." And we believe that the ſtyle of compoſition of Lulli and Rameau, ſo univerſally admired in France during the reigns of Louis XIV. and XV., are not likely to be ſoon reſtored to favour.

HAVE, LA, in *Geography*, a ſmall iſland, near the S.E. coaſt of Nova Scotia. N. lat. 44° 15'. W. long. 64° 10'.

HAVELANGE, a town of France, in the department of the Sambre and Meuſe, and chief place of a canton, in the diſtrict of Marche. The place contains 432, and the canton 6206 inhabitants, on a territory of 187½ kiliometres, in 23 communes.

HAVELBERG, a town of Brandenburg, in the mark of Pregnitz, almoſt ſurrounded and formed into an iſland by the river Havel, in its courſe from a lake in Mecklenburg to the Elbe, near Werben. The principal trade is that of diſtilling brandy, and alſo knitting ſtockings. Many ſhips are built here for the navigation of the Elbe, and great quantities of wood ſent from hence to Hamburg; 48 miles W.N.W. of Berlin. N. lat. 52° 51'. E. long. 12° 17'.

HAVEN, a ſea-port or harbour for ſhips. (See HARBOUR and PORT.) The word is derived from the Saxon *havene*, or the German *hafen*, or the French *havre*; which all ſignify the ſame thing.

HAVEN, *Eaſt*, in *Geography*, a townſhip of New Haven county, in Connecticut, on the E. ſide of New Haven harbour; containing 1004 inhabitants.—Alſo, a townſhip in Eſſex county, Vermont, W. of Maidſtone; 11 miles S.E. of the ſouthern end of Willughby's lake.

HAVEN, *New*, a county in Connecticut, extending along the ſound between Middleſex county on the E. and Fairfield county

county on the W., about 30 miles in length from N. to S., and 28 from E. to W.; divided into 14 townſhips, and containing, in 1800, 31,926 free perſons, and 236 ſlaves.—Alſo, a city of the above county, a ſeat of juſtice, and the ſemi-metropolis of the ſtate. It lies round the head of a bay which extends about four miles N. from Long iſland ſound. The plain on which it ſtands is circumſcribed by high hills or mountains; and it is bounded E. and W. by two ſmall rivers. Four ſtreets run N.W. and S.E., and are croſſed by others at right angles. Near the centre is the public ſquare, where are the public buildings, *viz.* a ſtate-houſe, three college edifices, a chapel and edifice for the library, &c., three churches for Congregationaliſts, and one for Epiſcopalians. This ſquare is encircled with rows of trees, and many of the ſtreets are ornamented with rows of trees. The city contains between three and four hundred neat dwelling houſes, principally of wood. Within its limits there were, in 1798, 547 houſes and upwards of 400 perſons. About one in 70 dies annually. As to pleaſantneſs of ſituation and ſalubrity of air, this city is hardly exceeded by any in America. It carries on a conſiderable trade with New York and the Weſt India iſlands, but it has manufactures of cards, ſnuff, linen, buttons, cotton, and paper. This place and Hartford are alternately the ſeats of the legiſlature. For an account of Yale college in this city, ſee COLLEGE. It is 40 miles S.W. by S. from Hartford, 83 from New York, 152 from Boſton, and 183 N.E. of Philadelphia. N. lat. 41° 18'. W. long. 72° 56'. —Alſo, a poſt-town in Addiſon county, Vermont, on Otter creek, between Middleburg and Vergennes.

HAVER, in *Rural Economy*, a term applied to oats in ſome of the more northern diſtricts of the kingdom.

HAVER *Meal*, a name ſometimes uſed to ſignify the meal which is prepared from oats by grinding and ſifting through proper ſieves for the purpoſe. This ſort of meal is much uſed for bread in the northern diſtricts of England and ſome other parts.

HAVERA, in *Geography*, a town of Aſiatic Turkey, in Natolia; 18 miles N.E. of Iſbarteh.

HAVERFORD, a townſhip of America, in Delaware county, Pennſylvania, containing 605 inhabitants.

HAVERCAMP, SIEGBERT, in *Biography*, diſtinguiſhed for his great and extenſive knowledge in philology and the ſcience of medals, was born about the year 1683. He exerciſed the office of preacher many years, in a ſmall village, in the iſland of Overflacke, between Holland and Zealand; and he afterwards became profeſſor of hiſtory, the Greek language, and rhetoric at Leyden, where he died in 1742. His learning and induſtry were diſplayed by many editions of ancient authors, and by original works. The editions of the claſſics by Havercamp are ſtill in conſiderable repute. The Lucretius of this editor, publiſhed in two volumes 4to. 1725, is the moſt complete and ſplendid edition of this fine poet, excepting that of the late Gilbert Wakefield. His "Diſſertatio de Numiſmate Alexandri Magni, quo quatuor ſumma Orbis Terrarum Imperia continentur, et de Nummis contorniatis;" and "Introductio in Antiquitates Romanas; et Antiquitatum Græcarum precipue Atticarum Deſcriptio brevis," are highly eſteemed. Havercamp was author of "A General Hiſtory of the affairs of Aſia, Africa, and Europe, ſince the end of the Fabulous Ages." His edition of "Nummophylacium Reginæ Chriſtinæ," folio, 1742, is a very elegant work, and contains the rareſt coins of the Roman emperors, of the firſt, ſecond, and third ſize, which were collected by queen Chriſtina of Sweden, at a very great expence. They were engraved from originals by Bartolo, and a Latin explanation of them was added by Havercamp. This editor took a large ſhare in J. Poleni Supplementa nova utriuſque Theſauri Romanarum Græcarumque Antiquitatum." Gen. Biog.

HAVERFORDWEST, in *Geography*, is the principal town in the county of Pembroke, South Wales, as well on account of its ſuperior extent, population, and trade, as from its having lately become the place of the grand ſeſſion. It owes its advantages principally to the circumſtance of ſtanding on the banks of the Daugleddy river, which forms a bay or harbour for packets and veſſels. It is built on the ſteep ſide of a high hill, ſo as to be very inconvenient, if not dangerous, for carriages and horſes; and more ſo as the ſtreets are very ill-paved. There are ſome good houſes, chiefly in the upper part; but the irregularity of the avenues, and the narrowneſs of all but one or two ſtreets, with the houſes piled confuſedly on one another, the lower windows of ſome looking down upon the roofs of others, render it intricate and unſightly on the entrance, though the approach is ſtriking. The market is one of the largeſt and moſt abundant in Wales; particularly for fiſh, which are brought here in the greateſt plenty and variety. Here is alſo a very large corn-market, and alſo a great fair for horſes and cattle of all kinds, on the 7th of July. Among the public concerns of the town are a good quay, a cuſtom houſe, a free ſchool, a charity ſchool, an alms' houſe, and three pariſh churches, reſpectively named St. Mary's, St. Martin's, and St. Thomas's. The town was made a county of itſelf by a charter from Edward IV. and ſends one member to parliament, having obtained that privilege 17 Henry VIII. The civil government is veſted in a mayor, ſheriff, town-clerk, two bailiffs, and 24 common-council, from whom the mayor is choſen. The mayor is admiral, coroner, eſcheator, and clerk of the markets. The caſtle is a ſtately object from the bridge, though it is conſiderably diſfigured by a part of it having been converted into a county goal. It is ſaid to have been built by Gilbert, earl of Clare, in the reign of king Stephen; but hiſtory is ſtrangely barren of events relating to it. The whole was well fortified with towers, and the walls are of great thickneſs. The ſect, calling itſelf the Unitas-Fratrum, but better known by the title of Moravians, is very numerous here. The Rev. John Gambold, one of their moſt eminent biſhops, was a native of Pembrokeſhire, and died in this town in 1771, aged 60. Haverfordweſt is 264 miles diſtant from London. The population, as returned in the year 1800, was 2880, inhabiting 613 houſes. Contiguous to the town is a cotton-mill, which employs about 150 perſons. At a ſhort diſtance to the ſouth are ſome remains of a priory of Black Canons, endowed, if not founded by Robert de Haverford, lord of this place. The walk to it from the town is a frequented promenade; and the ruins, if not highly pictureſque, are at leaſt venerable. The chapel is the chief part remaining. Malkin's "Scenery, Antiquities, and Biography of ſouth Wales," 2 vols. 8vo. 1807.

HAVERHILL, a market-town and pariſh, ſituated partly in the hundred of Hinckford and partly in that of Riſbridge, in the county of Suffolk, England, is eight miles W. of the town of Clare, and 58 N.N.E. of London. It contained, in the year 1801, 152 houſes and 1104 inhabitants, but was formerly of much greater extent, as may be inferred from the ruins of a ſecond church, and of a caſtle now remaining. At preſent it conſiſts of one broad ſtreet. Its chief trade is in the manufacture of checks, fuſtians, and cottons. The church is a large ancient edifice; beſides which here are two chapels for diſſenters. The town has a weekly market on Wedneſdays, and two annual fairs.

HAVERHILL, a poſt-town of America, in New Hampſhire, and half-ſhire town of Grafton county, ſituated on the E. ſide of Connecticut river, in Lower Coos; incorporated

in 1763, and containing 805 inhabitants. In it are a bed of iron ore, and a quarry of freeſtone, a fulling mill, oil mill, and other mill ſeats; 35 miles above Dartmouth college.—Alſo, a handſome poſt-town of Maſſachuſetts, in Eſſex county, ſituated on the N. ſide of Merrimack river, connected by an elegant bridge, 650 feet long and 34 wide, with Bradford. This town has a conſiderable trade, and veſſels of 100 tons burden have acceſs to it. It has diſtilleries and a brewery, a manufactory of ſail-cloth, and a number of neat, well-finiſhed houſes, diſpoſed principally in two ſtreets, the principal of which lies parallel with the river. Some veſſels are annually built here, and employed in the Weſt India trade. The whole townſhip contains 330 houſes, 2730 inhabitants, and four meeting-houſes, one for Baptiſts, and three for Congregationaliſts.

HAVERSACK, in *Military Language*, is a kind of bag, made of coarſe grey linen, in which the ſoldiers carry bread and proviſions on a march. They are only uſed in the field and in cantonments, each ſoldier having one.

HAVERSER, in *Geography*, a ſmall iſland of Scotland, near the W. coaſt of the iſland of Skye. N. lat. 57° 22'. W. long. 6° 30'.

HAVERSTRAW, a townſhip in Rockland county, New York, on the W. ſide of a bay of the ſame name, 10 miles long and about three wide; 35 miles N. of New York city, containing 1233 inhabitants.

HAVERY, two ſmall iſlands of Scotland, near the W. coaſt of Shetland. N. lat. 59° 59'. W. long. 1° 40'.

HAUGH, in *Agriculture*, is a name applied, in the northern parts of the iſland, to thoſe low, flat-lying tracts of land that extend on the ſides of rivers and brooks, in the vallies of mountains and other diſtricts, and which are liable to be frequently covered by them when in the ſtate of flood. They are generally of a rich quality, being conſtituted, in a great meaſure, by the depoſitions of the more fertile vegetable and animal matters which are let fall in ſuch circumſtances. See Soil.

Haugh-*land*, a name applied to that ſort of ground which is formed by a kind of depoſition from water, and which is commonly ſituated along the ſides of rivers and brooks. From its alluvial nature it is evidently of a rich fertile quality, and capable of producing almoſt every deſcription of grain crops, as well as thoſe of the graſs kind, when not liable to be overflowed by the waters of the rivers in the vicinity of ſuch lands. This ſort of land is, in many ſituations, capable of much improvement; but it has been ſuggeſted, in a late periodical work, that in ſome parts of Scotland theſe ſorts of lands are too frequently left either entirely, or in a great degree, to the mercy of the waters which paſs through them. In thoſe parts which are low and flat great loſs has been cauſed by this ſort of negligence; and a number of extenſive tracts, that lie on the banks of ſuch rivers and ſtreams, which might, with little trouble and expence, have been rendered extremely valuable, are, at this period, in a great meaſure uſeleſs to the community; and further, that in the more hilly and upland parts the loſs is ſtill greater; as in ſuch ſituations, the beſt ſoil, and that on which the chief dependence for grain is placed, is the haugh lands. In the whole of theſe tracts there are hollows between the different ranges of hills or highlands, through which various kinds of ſtreams take their courſe, upon the banks of which there is generally an extent of ſoil of good quality, conſiſting chiefly of the fineſt particles of earth that have been waſhed down by the rains from the high grounds, and which, by the accumulation of ages, have formed a bed of ſoil of ſuch depth and quality, as to be proper for the production of the moſt valuable kinds of crops. But in their preſent condition their value is conſidered as very ſmall in compariſon of what it might be under a different method of management, as, from the ſtagnation of water in ſome places, a very large portion is either covered with flags and ruſhes, or converted into a kind of moraſſes, and that which remains, in conſequence of the repeated inundations to which it is expoſed, partly from the overflowings of the rivers and ſtreamlets, and partly from the torrents which deſcend from the hills during heavy falls of rain, can never be cultivated with ſafety or advantage for grain crops. Even the ſmall ſpots which are reſerved for hay are far from yielding certain and profitable returns, the whole crop being, in numerous inſtances, either much damaged, or entirely carried off by the floods in a very few hours. On theſe accounts the cultivation of no inconſiderable extent of the beſt ſoils in the iſland has been abandoned; and the chief benefits which are at preſent derived from them are thoſe, in ſome inſtances, of bad paſtures, and in others of a quantity of coarſe ruſhy hay of but very little utility as the fodder of cattle. There are, however, ſituations in which theſe ſorts of land conſtitute ſome of the moſt rich feeding paſtures of this country, and are denominated holme lands. See Holme *Land*.

Haughs, in *Engineery*, are low flat meadows. Smeaton's Reports, vol. i. p. 381.

HAVIRAN, in *Geography*, a town of Aſiatic Turkey, in Natolia; 20 miles N.N.E. of Iſbarteh.

HAUKADAL, a town of Norway, in the dioceſe of Bergen; 70 miles N. of Bergen.

To HAUL, in *Sea Language*, to pull a ſingle rope without the aſſiſtance of blocks, or other mechanical powers. See Bowse.

To Haul *the wind*, is to direct the ſhip's courſe nearer to that point of the compaſs from which the wind ariſes.

HAULING-WAY, or Towing-Path, in *Engineery*, is a path on one of the banks B C of a canal, *Plates* I. and IV. *of Canals*, or of a navigable river for the uſe of the men and horſes or mules, who haul or tow the barges or other craft along.

HAUM, Halm, or *Hawm*, among *Farmers*, denotes the ſtem or ſtalk of corn, peaſe, beans, &c. from the root to the ear.

HAULME, in *Mining*, ſignifies, in ſeveral diſtricts, the helve or handle of a pick or tool uſed in mines.

HAUNCH, or Hanch, the hip, or that part of the body between the laſt ribs and the thigh.

The haunches conſiſt of three bones, joined together by cartilages, which in courſe of time grow dry, hard, and bony, ſo that in adults, the three only ſeem to conſtitute one continued bone.

Haunches, or hips of a horſe, are thoſe parts of the hind-quarters which extend from the reins or back, to the hough or ham.

The haunches of a horſe are too long, if, when ſtanding in the ſtable, he limps with his hind legs farther than he ought to do; and when the top or onſet of his tail is not in a perpendicular line to the top of his hocks, as it always is in horſes whoſe haunches are of a juſt length.

One of the moſt neceſſary leſſons in managing the great horſe, is that of *putting him upon his haunches*; which, in other terms, is called to *couple* him well, or to put him well together, or make him compact.

A horſe that does not bend or lower his haunches, throws himſelf too much upon his ſhoulders, and is heavy upon the bridle. To *drag the haunches*, is to change the leading foot in galloping

To make a horſe bend, or lower his *hips*, you muſt frequently make him go backwards, and make uſe of the aids of

of the hands, and of the calves of your legs, in giving good ſteps; and if that does not ſucceed, he muſt be tried upon a *calcade*, or ſloping ground, after the Italian faſhion.

Head in, and *hips in*. See HEAD.

To gallop with the *haunch in*. See GALLOP.

HAUNT, among *Sportſmen*, denotes the place to which game are accuſtomed to reſort; and among *Hunters*, it ſignifies the walk of a deer, or the place of his ordinary paſſages. See HUNTING.

HAUR, in *Geography*, a town of Perſia, in the province of Mecran; 136 miles N.W. of Tatta. N. lat. 26° 40'. E. long. 65° 28'.

HAVRE, a French term, ſignifying the ſame with *haven* or *harbour*.

HAVRE, *Le*, or *Havre de Grace*, in *Geography*, a ſea-port town of France, principal place of a diſtrict, and ſeat of a tribunal, in the department of the Lower Seine, ſituated on a marſhy ſoil, interſected with creeks and ditches, at the mouth of the Seine. From being the mere habitation of fiſhermen, conſiſting of a few houſes, in 1509, it was erected into a town, with its preſent appellation, by Francis I. Its harbour, from which, and an adjoining chapel, it derived its name, has advantages peculiar to itſelf; as the water does not begin to ebb till three hours after the full tide, ſo that many ſhips may depart in the ſame time. The baſin, which is reſerved for ſhips of war, is ſufficiently capacious to accommodate 30, and depth of water enough for thoſe of 60 guns. Before the revolution it was a place of great importance; beſides being the ſeat of a governor general and other officers, a bailiwic, admiralty, &c. it contained two churches, three convents, an hoſpital, poor-houſe, arſenal, magazines, and ſtore houſes neceſſary for the conſtruction and manning of ſhips. It is defended by high walls, large ditches filled with water and furniſhed with ſluices, a regular citadel with baſtions, &c. It was put into the hands of the Engliſh by the Hugonots during the civil wars of France; but ſurrendered in 1563. It has been bombarded at different times by the Engliſh, and in 1759 a great number of flat-bottomed boats, conſtructed for the invaſion of England, were deſtroyed by rear-admiral Rodney. The place contains 16,000, and the canton the ſame number of inhabitants, on a territory of five kiliometres, in one commune. N. lat. 49° 29'. E. long. 0° 12'.

HAVRE *de Grace*, or *Gras*, a poſt-town and port of Entry in Hartford county, Maryland, on the W. ſide of Suſquehannah river, at its mouth in Cheſapeak bay; containing about 40 houſes, and 250 inhabitants; 65 miles W.S.W. of Philadelphia. N. lat. 39° 39'.

HAURIANT, in *Heraldry*, denotes the poſture of a fiſh when borne directly upright.

HAUSAY, in *Geography*, one of the ſmaller Shetland iſlands, among the Out-Skeries. N. lat. 60° 42'. W. long. 0° 46'.

HAUSEBECK, a town of Weſtphalia, in the principality of Minden; 10 miles S.W. of Minden.

HAUSEN, a lordſhip of Germany, belonging to the princes of Furſtenberg, in the Schwartzade.—Alſo, a town of this lordſhip, on the Kinzig; 26 miles S.E. of Straſburg.

HAUSRUCK, a diviſion of the archduchy of Auſtria, deriving its name from a large foreſt, and containing, among others, the following chief towns, *viz.* Lintz, Wels, Gemunden and Efferding.

HAUSTELLUM, in *Natural Hiſtory*, a name given by ſome authors to a peculiar kind of ſhell-fiſh, of the purpura kind, which the French have named the *becaſſe*, and we the woodcock-ſhell. It is remarkable for its extremely long and ſlender beak. There are a very elegant echinated or ſpinoſe kind, and two or three ſmooth ones.

HAUSTILIA SUCCINA, a term uſed to expreſs that kind of amber, or more properly ſpeaking, thoſe maſſes of amber which are obtained by dragging the bottoms of the ſea near Pruſſia, or found on the ſhores, in diſtinction from thoſe pieces which are found foſſile in the ſame or other kingdoms.

The hauſtile amber is uſually found in irregular maſſes, for the moſt part wholly diveſted of its rough coat, and often broken, ſo that its original ſhape cannot well be aſcertained; but the foſſile amber generally carries the marks of its origin with it, and is either found in form of large drops of a roundiſh or oval figure, or elſe in flatted cakes, formed by the narrow ſpaces it is found in, between the layers of the matrix, which is always a kind of foliated or flakey ſubſtance, by ſome miſtaken for foſſile wood, or the barks of trees preſſed together, though, in reality, it is no other than a bituminous earth coagulated by ſalts, and hardened by the gradual evaporation of its ſuperfluous moiſture by the ſun's heat. Phil. Tranſ. N° 258. p. 18. See AMBER and MATRIX.

HAUT, Fr. in *Muſic*, equivalent to *Alto*, Ital., and *High* or *acute*, Engliſh.

HAUT-*deſſus*, Fr. upper or firſt treble, Engliſh.

HAUT *iſle*, or *iſle of Halt*, in *Geography*, the ſouthernmoſt of the large iſlands in Penobſcot bay, in Lincoln county and ſtate of Maine.

HAUTBOIS, in *Muſic*, a wind inſtrument, blown with a reed. It is the natural treble to the baſſoon, as their ſeveral names imply. *Haut-bois*, high wood, *Baſſon*, low ſound.

The hautbois conſiſts of four pieces, or joints, the upper piece to which the reed is fixed is the narroweſt. The tube increaſes in diameter to the end, which terminates with a wide mouth like the trumpet.

The hautbois goes lower than the German flute one tone, that is, down to C natural, and ſeldom, in full pieces, mounts higher than d in alt. This ſeems to have been an inſtrument in common uſe in the time of Shakſpeare, and to have had a companion or baſſoon for its baſe. Falſtaff, in deſcribing the lank and meagre figure of juſtice Shallow in his juvenile days, ſays:

> "The caſe of a *treble hautbois* was a manſion for him—— a court." Hen. IV. pt. 2.

Yriarte, in the notes to his Spaniſh poem, "La Muſic," regards its tone as nearer that of a human voice than any other wind inſtrument.

There is a ſpirit and hilarity in the tone of the hautbois which is gay and enlivening in allegros, and yet is not without expreſſion and complaint in pathetic ſtrains.

The moſt celebrated performers upon this inſtrument in this country during the laſt century, who are now no more, were San Martini, who arrived in England in 1723. His ſcholar Tommy Vincent, Fiſcher, and Simpſon, Martini and Fiſcher, were not only exquiſite performers on their inſtrument, but admirable compoſers. The concertos which Vincent uſed to play 50 years ago, which were known to be Martini's, were admirable, full of fire, taſte, and genius. They were never printed, nor did we ever know what became of them.

The concertos which Simpſon played were generally paſticcios, one movement from one compoſer, and one from another; but Fiſcher's, without being capricious, or *manieres*, were ſo much his own, that neither the compoſition nor performance reſembled any other.

HAUTE, in *Geography*, an iſland on the N E. part of the bay of Fundy. N. lat. 45° 20'. W. long. 65°.

HAUTE-*contre*, Fr. *Contralto*, Ital., and *Counter-tenor*, Engliſh, in *Muſic*, is the higheſt *natural* voice of a man.

In

In inſtrumental muſic, *Altus*, Lat. and *Alto Viola*, imply the tenor part for an inſtrument tuned an octave above the baſe; the tenor viol is frequently called by the Italians *viol da braccio*, on account of its reſting on the *arm*, in oppoſition to the *viol da gamba*, which reſts on the *leg*.

Haute-*taille*, Fr. *alto tenore*, Ital. is the voice-part which we ſimply call the *tenor*, written in the C clef, on the fourth line.

HAUTECOMBE, in *Geography*, a town of France, in the department of Mont Blanc, on the W. ſide of the lake Boargat; 12 miles N.N E. of Chambery.

HAUTE-FEUILLE, John, in *Biography*, known for his great genius and ſkill in mechanics, was born at Orleans in the year 1647. His father was a baker in that city, but was able, fortunately, to obtain for the youth the patronage of the ducheſs de Bouillon, who beſtowed on him the advantages of a liberal education. Having gone through the preparatory ſtudies with reputation, he embraced the eccleſiaſtical life, and was preſented, through the intereſt of the ducheſs, with ſeveral valuable benefices. He accompanied her in her travels through ſeveral countries on the continent and England, and upon her death ſhe left him an annuity for his life. His favourite ſtudy was the ſcience of mechanics, particularly its application to clock-work, in which he made many diſcoveries of ſingular uſe. He invented the method of moderating the vibration of the balance in watches by means of a ſmall ſteel ſpring, incloſed in a box which has ſince been made uſe of. This diſcovery was communicated by the author to the Royal Academy of Sciences in 1674, and the watches into which it was introduced were called, by way of eminence, "pendulum watches;" not that they really have pendulums, but becauſe they nearly approach in accuracy to the machines which are regulated by pendulums. This invention was perfected by Huygens, who claimed the merit of the original diſcovery, but Hautefeuille ſhewed, in a work which he publiſhed in 1675, that he was entitled to that merit. He was author of many other curious treatiſes, among which are "The Perpetual Pendulum;" "The art of breathing under water, &c.:" "Reflections on certain machines for raiſing water:" a treatiſe on the horizontal moon, another on the longitudes, and one on the tides, to prove the motion of the earth. He died at Orleans in the year 1724, when he was about ſeventy-ſeven years of age. Moreri.

HAUTEFORT, in *Geography*, a town of France, in the department of the Dordogne, and chief place of a canton, in the diſtrict of Périgueux; 18 miles N.E. of Périgueux. The place contains 889, and the canton 8261 inhabitants, on a territory of 195 kiliometres, in 17 communes.

HAUTEGOR, a town of Hindooſtan, in the circar of Cicacole; 22 miles N.W. of Ganjam.

HAUTELUCE, a town of France, in the department of Mont Blanc; 13 miles N.E. of Conflans.

HAUTERIVE, a town of France, in the department of the Drôme; 13 miles N. of Romans.

HAUTE-RIVIE'RE, a town of France, in the department of the Rhône and Loire; 18 miles W. of Lyons.

HAUTEVILLE, a town of France, in the department of the Ain, and chief place of a canton in the diſtrict of Belley; ſix miles E. of St. Rambert. The place contains 674, and the canton 4549 inhabitants, on a territory of 137½ kiliometres, in 10 communes.—Alſo, a town of France, in the department of the Marne; nine miles S.E. of Vitry.

HAUTIMABAD, a town of Hindooſtan, in the ſoubah of Delhi; 20 miles S. of Secundam.

HAUTINDAR, a town of Hindooſtan, in Lahore; 28 miles S.W. of Lahore.

HAW. A ſmall parcel of land is ſo called in Kent; as a *hemp-haw*, or *bean-haw*, lying near the houſe, and incloſed for thoſe uſes. But ſir Edward Coke, in an ancient plea concerning Feverſham in Kent, ſays, haws are houſes. See Haga.

Haw, Hawgh, or Howgh, is uſed, in the north of England, for a green plot in a valley.

Haw, among *Farriers*, &c. an excreſcence reſembling a griſtle growing between the nether eye-lid and the eye of a horſe, or other beaſt, and which will put the eye quite out, if not timely taken away.

It comes by groſs, tough, and phlegmatic humours, falling from the head, and knitting together, which in the end grow to this infirmity; the ſigns whereof are the watering of the eye, and involuntary opening of the nether ſide.

Every common farrier can cut it out: the affected beaſt is to be held faſt by the head, and with a ſtrong double thread, a needle is to be put in the midſt of the upper eye-lid, and tied, if it be a bullock, to his horn; then taking the needle again, with a long thread, and putting it through the griſtle of the haw, with a ſharp knife cut the ſkin finely round, and ſo pluck out the haw. That done, they dreſs the eye, take out the blood, waſh it with beer or ale, and caſt in a good deal of ſalt; then waſh it again, afterwards ſtroaking it down with their hands, and ſo let him go. To cure a ſheep of this malady, they drop into the eye the juice of chamomile, or crow's-foot.

Haw, a common name applied to the fruit of the white thorn. This kind of haw has been found uſeful as a food for ſome ſorts of animals, as the horſe, hog, &c. inſtead of grain.

HAWARDEN, in *Geography*, a market town and pariſh in the hundred of Mold, and county of Flint, North Wales, is a large town, having the ruins of a caſtle, and built in a ſituation which commands an extenſive view over a flat tract of marſh land towards the river Dee, to Cheſter, &c. It is about ſeven miles to the weſt of that city, and contained, in the year 1800, 769 houſes, and 4071 inhabitants. In the vicinity of the town are ſome manufactures of earthen ware, for the making of which the clays here are peculiarly adapted. Here is alſo an iron foundery for cannon, &c. But the place is more particularly diſtinguiſhed for its ancient caſtle, which has been a building of much ſtrength and note. It is ſaid to have been erected on the ſcite of a more ancient fortreſs, ſoon after the Norman conqueſt; for Roger Fitz-Walerin, ſon of one of king William's officers, is known to have poſſeſſed it. This manor was afterwards given by Llewellyn, prince of Wales, to Robert de Montalt, who was reſtrained from building a caſtle on it for 30 years after poſſeſſion, whereby it is inferred that the former building was deſtroyed. Henry VI. granted it to ſir Thomas Stanley, in whoſe family it continued till the civil wars, when it was purchaſed by ſerjeant Glynn. This fortreſs ſtands on a hill, and is now included within the ſcite of ſir William Glynn's park. To the weſt of the church is a mount called Trumons-hill, which has ſome traces of an encampment on its ſummit; and at about two miles diſtant is Eulo caſtle, conſiſting of a ſquare area, with two round towers. Theſe are ſeated on the edge of a deep wooded dingle, and are overgrown with ivy, &c. The ſituation is peculiarly romantic, and the ſcenery highly pictureſque. See Pennant's Tour in Wales, vol. ii. p. 88. 92, &c.

HAWES, William, M D. in *Biography*, chiefly diſtinguiſhed as the founder of the Humane Society, was born at Iſlington in the year 1736, and was educated at St. Paul's ſchool. In 1759 he began to practice as an apothecary in the Strand; but for ſeveral years his practice was local and

and of ſmall extent, although he had been honoured with the friendſhip of ſome diſtinguiſhed literary characters. His firſt appearance as an author was in 1774, on the occaſion of the death of the celebrated Dr. Goldſmith, who, in ſpite of the remonſtrances of Mr. Hawes, had taken a large doſe of James's powder, which produced a violent effect, and was believed to have accelerated his death. Mr. Hawes, therefore, publiſhed "An Account of the late Dr. Goldſmith's illneſs, ſo far as relates to the exhibition of James's powders, together with Remarks on the Uſe and Abuſe of powerful Medicines in the beginning of acute Diſeaſes." In the year 1773, Dr. Cogan had tranſlated and publiſhed the memoirs of a ſociety, inſtituted at Amſterdam in 1767, for the purpoſe of recovering perſons apparently dead from drowning. This immediately excited the zeal of Mr. Hawes for the eſtabliſhment of a ſimilar inſtitution in the metropolis, which he had the ſatisfaction of ſeeing accompliſhed in 1775, in the formation of the Royal Humane Society, of which his majeſty became the patron. From the reports of the ſociety, which Dr. Hawes publiſhed at intervals, it appears that ſeveral thouſands of individuals have been ſaved to their friends and the community, moſt of whom would have inevitably periſhed, if the means recommended by the ſociety had not been enforced. He was appointed regiſter of the ſociety, and afterwards treaſurer. In the autumn of 1776, he commenced a courſe of lectures on the ſubject of ſuſpended animation, which he continued to deliver for ſeveral years with great intereſt and enthuſiaſm. In 1777, he publiſhed an "Addreſs to the Public on premature Death and premature Interment," of which, with his uſual liberality, he diſtributed ſeven thouſand copies in various parts of the kingdom. By theſe unwearied efforts in the cauſe of humanity, he had now acquired much public reputation and eſteem, and was induced to relinquiſh his practice as an apothecary; and in the year 1781, he obtained a diploma of doctor of medicine, and was elected, in a very honourable manner, one of the phyſicians to the Surrey diſpenſary. In the ſame year, he publiſhed "an Addreſs to the king and parliament of Great Britain, on preſerving the lives of the inhabitants, and on regulating the bills of mortality," which inculcated many uſeful regulations, and expoſed the groſs errors in the management of theſe records of death. Dr. Hawes continued active in his benevolent purſuits, until towards the cloſe of the year 1808, when a diſeaſe in the bladder, which had occaſioned ſeveral fits of ſevere illneſs for a few years preceding, terminated his exiſtence on the 6th of December, at the age of 73. See Ann. Med. Regiſter for 1808.

HAWFINCH, in *Ornithology*. See LOXIA *Coccothraustes*.

HAWICK, in *Geography*, an ancient baronial town in the county of Roxburgh, Scotland, was the chief and ſhire town during the thraldom of Roxburgh, and is ſeated at the confluence of the ſmall river Slitrigg with the Teviot. It is a burgh, or barony, independent of the lord; and had a charter granted it in 1545 by James Douglaſs, comes de Dramlanark. This was confirmed by queen Mary, and inveſts the inhabitants or burgeſſes with the privilege of electing two bailiffs, and two repreſentatives of each of the ſeven incorporations, which, with 15 counſellors elected for life, manage the civil polity of the town. Thus it poſſeſſes the ſame privileges and immunities, excepting that of ſending members to parliament, as a royal burgh. In the town is a conſiderable carpet manufactory, and lately the ſtocking trade has been introduced. Here are a weekly market and two annual fairs, beſides an annual mart, called a tryſt, for black cattle. A neat town-houſe has been built here, and the magiſtrates have ſupplied the town with water, by means of leaden pipes. As a border town, Hawick was frequently involved in ruin during the ages of hoſtility. Among other inſtances it is ſaid to have been wholly, or nearly conſumed by fire in April 1570. The church here, Mr. Chalmers ſtates to have been dedicated in 1214: it was long made uſe of as a court-houſe; and at one time, while the ſheriff of Roxburgh was holding his court here, he was ſeized by Wm. Douglaſs, the knight of Lidiſdale, and carried off to Hermitage caſtle, where he was ſtarved by ſolitary confinement. (Sinclair's Statiſtical Account of Scotland, vol. viii.; alſo Chalmers's Caledonia, vol. ii. p. 115, 175.)

HAWK, in *Ornithology*. See FALCO.

The hawk makes the ſubject of a particular art, called *hawking*, or *falconry*; which ſee.

Naturaliſts diſagree about the number and diviſion of the hawk kind. The moſt commodious diſtribution is that into *long-winged*, and *ſhort-winged hawks*.

To the long-winged, which may be alſo called the *falcon* tribe, belong the falcon, haggard-falcon, jerfalcon, lanner, hobby, ſaker, merlin, and bawler; all which are reclaimed, manned, fed, and mewed, much after the ſame manner. Of the ſhort-winged ſpecies, or hawks properly ſo called, are the *gos-hawk* and *ſparrow-hawk*.

The former are generally brought to the lure, and ſeize their prey with the foot; breaking the neck-bone with their beak, before they proceed to plume or tire it; the latter are brought to the fiſt, and kill their game by ſtrength and force of wing, at random, and proceed immediately to plume them.

It is to be noted, that the female of all birds of prey is much larger, ſtronger, and more courageous, than the male; which is diſtinguiſhed from it by ſome diminutive name. Thoſe of the falcon and gos-hawk are called *tiercels*, or *tiercelets*; that of the jerfalcon, *jerkin*; that of the merlin, *jack*; that of the hobby, *robbin*; that of the ſparrow-hawk, *muſket*; and that of the lanner, *lanneret*.

The hawk has different names, according to their different ages. The firſt year ſhe is called a *ſoarage*; the ſecond, an *interview*; the third, a *white hawk*; the fourth, a *hawk of the firſt coat*.

Add, that they have different denominations, according to the different ſeaſons when they are taken. Thoſe taken in the ayrie, are called *eyeſſes* or *nyeſſes*; thoſe which had forſaken it, and were fed in ſome places not far off, by the old ones, *branchers*; thoſe which had begun to prey for themſelves, *ſoar-hawks*; thoſe which have changed their feathers once or more, *mewed hawks*; and thoſe which lived at large, and preyed for themſelves about the woods, *haggards*. For the ſeveral ſpecies of hawks formerly uſed in the art of *hawking*, we refer to the articles FALCO and FALCONRY. See alſo HAWKING.

The Engliſh legiſlature has thought theſe birds worthy of its protection: taking their eggs out of any man's ground, is puniſhable by impriſonment for a year and a day, and by a fine at the king's will; one half to him, and half to the owner of the ground. (Stat. 11 Hen. VII. cap. 17.) Stealing hawks, in diſobedience to the rules preſcribed by the ſtat. 37 Edw. III. cap. 19. is felony, 3 Inſt. 98. See FALCONRY.

HAWK, *Make*, in *Falconry*, a name given to an old ſtaunch hawk, which being uſed to fly, will teach a young one to fly.

HAWK-*weed*, in *Botany*. See HIERACIUM.

HAWK-*weed*, *Baſtard*, in *Botany*. See CREPIS.

HAWK-*weed*, *Trailing*, *crooked-ſeeded*. See HYOSERIS.

HAWK-*weed*, *Woolly*. See ANDRYALA.

HAWK-*moth*, in *Entomology*. See SPHINX.

HAWK-*owl*, in *Ornithology*, the STRIX *Hudſonia*, which ſee.

HAWK-*owl*, *Little*. See STRIX *Indica*.

HAWK'S *Bay*, in *Geography*, a bay on the coaſt of W. Florida, W. of the mouth of Mobile harbour, between Pelican and Dauphin iſlands; part of which having good anchorage, is very convenient for ſmall veſſels.

HAWKE, EDWARD, *Lord*, in *Biography*, ſon of a bariſter of eminence, was regularly educated for the navy, paſſed through all the ſubordinate ſtations; and in 1734 he was made a poſt-captain. In an engagement between the combined fleets of France and Spain, and that of England, under admirals Matthews and Leſtock, captain Hawke was the only one to whom a Spaniſh ſhip of the line ſtruck. On this occaſion he broke the line of battle to ſuccour two Engliſh ſhips, for which act, committed by the ardour of heroiſm, he incurred the ſuſpenſion of his commiſſion, but it was honourably reſtored to him. This was in 1744, and in 1747 he was made rear admiral of the white, and ſhortly after, having the command of 14 ſhips, he fell in with a Weſt India fleet, convoyed by nine men of war, out of which he captured ſeven. For his valour he was rewarded with the knighthood of the Bath, and raiſed to the rank of vice-admiral of the blue. In the ſeven years' war ſir Edward Hawke performed many national and important exploits, which will long live in the naval records of our country. In 1759 the French threatened an invaſion of England, and a large fleet was collected for the purpoſe, which ſir Edward kept blocked up cloſe in Breſt for many months. In November a ſtorm drove him into Torbay, the enemy put to ſea, an engagement ſoon enſued, in which the approach of night alone ſaved the French from total deſtruction. The reſult was, that the French admiral-ſhip and another were burnt, two were ſunk, and one taken, all of the line; and ſeven more were obliged to take ſhelter in the mouth of a narrow river. Hawke was now rewarded with a penſion, and his name ſtood the very higheſt in his profeſſion in popular celebrity. He had not obtained theſe honours without riſk: the weather was rough and tempeſtuous, and the nature of the coaſt was not only hazardous by the number of its ſand-banks, ſhoals, &c. but unknown to the Britiſh ſailors, and it required the utmoſt reſolution in the commander to attempt an attack on this occaſion. But ſir Edward Hawke, ſteeled with the integrity and fortitude of his mind, animated with the love of his country, and well acquainted with the magnitude of the ſtake on which the ſafety of that country, in a great meaſure, depended, was reſolved to run extraordinary hazards to fruſtrate the project for annoying his fellow-ſubjects. When his pilot, an able and ſkilful man, remonſtrated that he could not obey his order, without the moſt imminent dangers, the admiral replied, "You have done your duty in pointing out the difficulties, you are now to comply with my order, and lay me along the Soleil Royal." Victory, as we have ſeen, enſued, which not only defeated the projected invaſion, but gave the finiſhing blow to the navy of France, which was unable to undertake any thing of conſequence during the remainder of the war. Sir Edward was in 1765 raiſed to the poſt of vice-admiral of Great-Britain; in the year 1770 he was placed at the head of the admiralty, and in 1776 created a peer of Great-Britain, with the title of baron Hawke. He died in 1781. Smollet's Continuation, vol. iv. and v.

HAWKES' *Temperaments of the Muſical Scale*. The Rev. William Hawkes in 1798 publiſhed an octavo pamphlet, entitled "A Treatiſe on the Theory and Practical Syſtem of Muſic," ſold by Cawthorn, and in 1805, a folio pamphlet with a ſimilar title, ſold by Clementi, the objects of which were, to recommend an irregular douzeave ſyſtem of temperament, which he ſaid (p. 7, of the firſt pamphlet) was *then practiſed*, wherein the progreſſion of eight-fifths upwards, *viz.* C, G, D, A, E, B, ※ F, ※ C, and ※ G, are each flattened $\frac{1}{4}$th of a major comma, except the laſt, which is kept perfect: and the progreſſion of three-fifths downwards, *viz.* c, F, ♭ B and ♭ E, which are each alſo flattened $\frac{1}{4}$ c, except the laſt, which is kept perfect: whence it happens, that the reſulting fifth, between ※ G and ♭ E, preſents a *wolf* or fifth, *ſharpened* 7.8 Σ + 8 *m*, or almoſt $\frac{3}{4}$ths of a comma; a circumſtance no where hinted at in the publications above quoted, nor did their author ſeem to underſtand or admit this or other facts, in a converſation with the writer of this, on the ſubject of this and other large wolves which would occur, in the application of this ſyſtem to practice. In the Philoſophical Magazine, vol. xxvi. p. 171, vol. xxviii. p. 304, vol. xxx. p. 5, and vol. xxxvi. p. 47, a good deal of information has been publiſhed reſpecting this ſyſtem, which we ſhall not repeat, but lay before our readers, all which ſeems further neceſſary to enable muſicians or theoriſts to judge for themſelves, of the merits and defects of this ſyſtem, formerly ſo much extolled by its author.

A TABLE of the Lengths of Strings and Vibrations in 1', made by each Note in Mr. Hawkes' Irregular Douzeave, above the Tenor clef C; with the beats per ſecond, made by every concord above theſe Notes.

Notes	lengths of ſtring.	vibrations in one ſecond.	3ds ♭	IIIds ※	4ths ※	Vths ♭	6ths ♭	VIths ※
			Beats made in one ſecond.					

The

The beatings are all flat or ſharp, as expreſſed in the titles at the bottom of each column, except the 4th on ♭ E, and the Vth on ✻ G, which are otherwiſe expreſſed.

The examination of the calculations of any of theſe beats is perfectly eaſy, by Mr. Farey's theorem for beats, given in our article *Grave* HARMONICS, by help of the vibrations in the 3d column; thus for the 3d, C ♭ E or $\frac{5}{4}$, at bottom of col. 4, we have, $6 \times 240 - 5 \times 285.8614 = 10.693$ beats per ſecond, and ſo of others; doubling the vibrations for the notes in the ſuperior octave, wherever they are wanted. It may be proper here to obſerve, that the ſyſtem will not be correctly aſcertained by means of the beats in the above table, unleſs the pitch of C of the tenor clef line on the inſtrument give 240 vibrations, or very near it, aſcertained by the methods pointed out in our article CONCERT-PITCH.

In Auguſt 1807, the Rev. Mr. Hawkes iſſued printed propoſals for a ſubſcription of 60 guineas (to be made to Mr. Anderſon), for completing an inſtrument for the ſubſcribers, after a plan that had then lately occurred to him, "of a keyed inſtrument in which *true chords* are acquired *throughout the twenty-four keys*," without the addition of a ſingle finger key. It is probable that this propoſal produced no effect, for on the 25th of July 1808, Mr. Hawkes took out a patent for improvements on muſical keyed inſtruments of 12 fixed tones, the ſpecification of which may be ſeen in the Repertory, 2d ſeries, vol. xiii. p. 248; whence it ſeems, that Mr. Hawkes' invention conſiſts in doubling the uſual number of ſtrings or pipes, or extending them to 24 in the octave; twelve of which are to be tuned to a chromatic ſharp ſcale, and 12 to a chromatic flat ſcale, the natural notes or long keys in each ſcale being uniſons, and the whole key-board moves to the right or to the left by the action of a pedal, ſo that the keys act at the ſame time on all the five ſharps, or on all the five flats, without altering the pitch of the intermediate natural notes. And thus, with the help of 24 ſtrings or pipes, no more than 17 intervals are acquired in the octave on theſe patent inſtruments of Mr. Hawkes; the patentee having been entirely ſilent in this ſpecification, and in a controverſy in which he has been engaged with ſeveral, in Dr. Kemp's "Muſical Magazine," as to the preciſe mode or principles which he adopts in tuning, or adjuſting theſe 17 intervals, but contents himſelf on all occaſions with aſſerting, that on his organs and piano-fortes, "every common chord, major and minor, throughout the 24 keys, are perfect to the niceſt ear." It becomes neceſſary for us here to remark, that Mr. Hawkes having no ſounds for E ✻ or F ♭, or for B ✻ or C ♭, if in the table of conſonances in plate 19 of Dr. Smith's Harmonics, we draw other diagonal dotted lines, two notes higher, (ſo as to include D ✻ and A ✻) and other three notes lower, (ſo as to include A ♭, D ♭, and G ♭), which are Mr. Hawkes' five additional notes, (than thoſe which the Doctor has drawn, to repreſent the common or douzeave ſcale,) it will appear manifeſt that the nine middlemoſt keys B ♭, F, C, G, D, A, E, B, and F ✻, only can be without *wolves* in their concords, with 17 notes; and that as we proceed to modulate from thence upwards by ſharps, C ✻ has a falſe IIId (for want of E ✻), G ✻ has a falſe IIId and a falſe VIth (for want of B ✻ and E ✻), D ✻ has a falſe IIId and a falſe VIth (for want of F ✻ ✻ and B ✻), and A ✻ has a falſe IIId, a falſe Vth, and a falſe VIth, (for want of C ✻ ✻, E ✻ and F ✻ ✻): in like manner if we modulate downwards by flats, E ♭ has a falſe 6th, (for want of C ♭), A ♭ has a falſe 3d, and a falſe 6th (for want of C ♭ and F ♭), D ♭ has a falſe 3d, a falſe Vth, and a falſe 6th, (for want of F ♭, A ♭, and D ♭♭), and G ♭ has a falſe 3d, a falſe 4th, a falſe Vth, and a falſe 6th, (for want of B ♭♭, C ♭, D ♭, and E ♭♭). Giving ſix major common chords, *viz.* in the keys C ✻, G ✻, D ✻, A ✻, D ♭, and G ♭, and five minor common chords, *viz.* in the keys A ✻, E ♭, A ♭, D ♭, and G ♭, in all of which falſe notes or wolves occur; and every three of theſe, *viz.* C ✻ and G ✻ major, and E ♭ minor, are eſſential to completing the number of 24 uſual keys, of whoſe *perfection* the patentee and his advocates boaſt.

We ſhould perhaps have ſpared ourſelves and our readers the pains of expoſing the fallacies in the puffs of this reverend patentee, were it not that a lecturer on muſic at the Royal Inſtitution, and at the Surrey Inſtitution, had made their defence, and the exhibition of theſe patent inſtruments with that view, parts of his lectures; the patentee, by oppoſing the obtaining of a ſubſequent patent by Mr. D. Loeſchman for a vaſtly ſuperior invention, and his miſrepreſentations and that of his partizans ſince, rendered it a neceſſary piece of juſtice at our hands: and becauſe M. Loeſchman's inſtruments, containing *no more ſtrings than Mr. Hawkes'*, can render all the above chords true, according to any given ſyſtem of temperament, excepting only the minor key of G ♭, (he having no E ♭♭) or 33 keys in the whole, inſtead of the 23 keys which Mr. Hawkes' might be made to produce, including A ♭ major, and D ✻ minor, which are unuſual keys, or coincident with G ✻ and E ♭, on common inſtruments. Beſides all this, Mr. Hawkes' inſtruments are incapable of executing the multitude of paſſages in the beſt authors, ancient and modern, where both flats and ſharps occur in the ſame ſtrain, of which ample liſts have been given in the Muſical Magazine above quoted; but on D. Loeſchman's inſtruments, this can be done with the utmoſt facility, and as inſtantaneouſly as one of ſix pedals can be put down with the foot, placed ready above it, in moſt inſtances which can occur; while the perfection of his mechaniſm guards againſt both the flat and the ſharp of the ſame finger-key ſounding together, if the pedal is moved while the key is down, which it can be, without deranging any thing, and never more than one of his pedals require to be uſed at the ſame time.

HAWKE, in *Geography*, a townſhip of America, in Rockingham county, New Hampſhire, incorporated in 1760, and containing 389 inhabitants.

HAWKE *Bay*, a bay on the E. coaſt of Labrador. N. lat. 53° 10′. W. long. 55° 50′.

HAWKE's *Bay*, a bay on the E. coaſt of the northernmoſt iſland of New Zealand, in the South Pacific ocean.

HAWKE, *Cape*, a cape on the coaſt of New Holland, ſo called by Cook in 1770. S. lat. 32° 14′. W. long. 207° 30′.

HAWKE's *Harbour*, an arm of Igornachoix bay, Newfoundland.

HAWKE *Iſland*, a ſmall iſland near the E. coaſt of Labrador. N. lat. 53° 10′. W. long. 55° 30′.

HAWKERS, anciently were fraudulent perſons, who went from place to place, buying and ſelling braſs, pewter, and other merchandize, which ought to be uttered in open market. In this ſenſe the word is mentioned, anno 25 Hen. VIII. cap. 6. and 33 ejuſdem, cap. 4.

The appellation hawkers ſeems to have ariſen from their uncertain wandering, like thoſe who, with hawks, ſeek their game where they can find it.

The term is now uſed as ſynonymous with pediar; a perſon who travels about the country ſelling wares.

By 29 G. III. c. 26, and 35 G. III. c. 91, every hawker muſt take out an annual licence, for which he muſt pay 4*l.*, and if he travel with a horſe, aſs, or mule, for every one of them

them 8*l.* If he travels without a licence, or contrary to it, and has it not ready to be produced, he forfeits, for every offence, to the informer, and the poor of the parish where discovered, 10*l.* If he travels with a forged licence, he forfeits 50*l.*; and by 25 G. III. c. 78, 100*l.*, half to the king and half to him that shall sue, and be also liable to punishment for forgery: 9 and 10 W. c. 27. Hawkers refusing to produce their licences, may be detained, and on proof of their trading without a licence, forfeit 40*l.*

The acts relating to hawkers do not extend to makers of goods, or their agents; or to those who sell goods in fairs or markets; to the sellers of fish, fruit, or other victuals; nor to the venders of books and newspapers. (9 and 10 W. cap. 27. 3 and 4 Anne, cap. 4. 29 G. III. c. 26.) But hawkers shall not, by virtue of their licence, sell or offer to sale, any tea, or spirituous liquors, though with a permit, under the penalty of having the same seized, and imprisonment and prosecution of the offender. (9 Geo. II. cap. 35.) And if any foreign cambrick or French lawn shall be found in the possession of any hawker, &c. the same shall be forfeited together with all the goods in his pack; and he shall be adjudged to have forfeited his licence (7 Geo. III. cap. 43.) No hawker shall expose goods to sale in any part of a market town, but the public market-place: nor shall he sell any goods by auction, on pain of forfeiting 50*l.* 29 G. III. c. 26.

HAWKESBURY's Island, in *Geography*, an island in an arm of the Pacific ocean, discovered by Vancouver; 33 miles long, and from four to 10 broad. N. lat. 53° 36'. W. long. 231° 4'.

Hawkesbury's *River*, a river of New South Wales, that runs into Broken bay.

Hawkesbury *Township*, a township in the county of Glengary, Upper Canada, on the Ottawa river, adjoining Lower Canada.

HAWKESWORTH, John, in *Biography*, was born at Bromley, in Kent, in the year 1715, and bred to the trade of a watchmaker, or, according to sir John Hawkins, he spent the early part of his youth in the office of an attorney. By his own talents he fitted himself for literary occupations, and in 1744 he became successor to Dr. Johnson, in compiling the parliamentary debates for the Gentleman's Magazine. For this he wrote many pieces of poetry, during several successive years, under the signature of H. Greville. In 1752 he embarked in a periodical work under the title of "The Adventurer," which was continued to the 140th number, one half of the papers being of his own composition. These essays were well received by the public, and highly merited the success which they obtained by the purity of their morals, the elegance of their critical disquisitions, and the knowledge they displayed of life and manners. The papers which have most generally been admired, are those containing eastern tales, or stories of domestic life, in the former of which is exhibited a fine imagination, and in the latter a very considerable knowledge of the human heart. They have been since reprinted in almost all sizes and forms, and are deservedly ranked among the best English classics. Their moral tendency was so excellent, that archbishop Herring spontaneously conferred on the author the degree of doctor of laws. Dr. Hawkesworth appeared as writer for the stage, and was successful in altering, at the desire of Garrick, Dryden's comedy of Amphytrion; and also in the original pieces entitled "Zimri," an oratorio; "Edgar and Emmeline," a dramatic entertainment, and "A Fairy Tale," a very elegant fancy piece. In 1761 he published, in two volumes 12mo., an oriental tale, entitled "Almoran and Hamet," which possesses much merit as a romance of the serious and dignified class. He edited the works of Dean Swift, to which he prefixed a life of the author: also, the "Letters of Dean Swift and several of his friends," &c.: and in 1768 he gave the world an excellent translation of Telemachus. In 1772 he was employed to compile into one narrative an account of all the voyages of discovery made by command of his present majesty to that period of his reign. This work was printed in three volumes 4to. adorned with charts, maps, and views, and the editor was remunerated with the large sum of 6000 pounds. He then became an East India director, and died in the year 1773. He was a man of irritable passions and exquisite sensibility, but friendly, social, and humane. He exhibited in conversation, and all the connections of life, the manners of a gentleman and scholar.

HAWKING, the art or exercise of chasing and taking wild fowls, by means of hawks, or birds of prey.

Hawking is the same thing with what we otherwise call *falconry*; which see.

The word *hawking*, in its latitude, also includes the taming and disciplining of hawks, and fitting them for the sport.

Hawking, though an exercise now much disused among us, in comparison of what it anciently was, does yet furnish a great variety of significant terms, which still obtain in our language. Thus the parts of a hawk have their proper names. The legs, from the thigh to the foot, are called *arms*; the toes, the *petty singles*; the claws, the *pounces*. The wings are called the *sails*; the long feathers thereof, the *beams*; the two longest, the *principal feathers*; the next thereto, the *flags*. The tail is called the *train*; the breast-feathers, the *mails*; those behind the thigh, the *pendant feathers*. When the feathers are not yet full grown, she is said to be *unsummed*; when they are complete, she is *summed*. The craw, or crop, is called the *gorge*. The pipe next the fundament, where the fæces are drawn down, is called the *panel*; the slimy substance lying in the panel, is called the *glut*. The upper and crooked part of the bill is called the *beak*; the nether part, the *clap*; the yellow part between the beak and the eyes, the *sear*, or *seer*; the two small holes therein, the *nares*.

As to her furniture: the leathers, with bells buttoned on her legs, are called *hewits*. The leathern thong, whereby the falconer holds the hawk, is called the *leash* or *leash*; the little straps, by which the leash is fastened to the legs, *jesses*: and a line or packthread fastened to the leash, in disciplining her, a *creance*. A cover for her head to keep her in the dark, is called a *hood*: a large wide hood, open behind, to be worn at first, is called a *ruffler hood*: to draw the strings, that the hood may be in readiness to be pulled off, is called *unstriking the hood*. The blinding a hawk just taken, by running a thread through her eye-lids, and thus drawing them over the eyes, to prepare her for being hooded, is called *seeling*. A figure or resemblance of a fowl, made of leather and feathers, is called a *lure*. Her resting place, when off the falconer's fist, is called the *perch*. The place where her meat is laid is called the *hack*; and that wherein she is set, while her feathers fall and come again, the *mew*.

Something given to a hawk, to cleanse and purge her gorge, is called *casting*. Small feathers given her to make her cast, are called *plumage*. Gravel given her to help to bring down her stomach, is called a *rangle*. Her throwing up filth from the gorge after casting, is called *gleaming*. The purging of her grease, &c. *enseaming*. A being stuffed is called *gurgiting*. The inserting a feather in her wing in lieu of a broken one, is called *imping*. The giving her a leg, wing, or pinion of a fowl to pull at, is called *tiring*. The neck

neck of a bird the hawk preys on, is called the *inke*. What the hawk leaves of her prey is called the *pill*, or *pelf*.

There are alſo proper terms for her ſeveral actions. When ſhe flutters with her wings, as if ſtriving to get away, either from perch or fiſt, ſhe is ſaid to *bate*. When ſtanding too near, the fighting with each other, is called *crabbing*. When the young ones quiver, and ſhake their wings in obedience to the elder, it is called *cowring*. When ſhe wipes her beak after feeding, ſhe is ſaid to *feak*. When ſhe ſleeps, ſhe is ſaid to *jouk*. From the time of exchanging her coat till ſhe turn white again, is called her *intermewing*. Treading is called *cawking*. When ſhe ſtretches one of her wings after her legs, and then the other, it is called *mantling*. Her dung is called *muting*: when ſhe mutes a good way from her, ſhe is ſaid to *ſlice*; and when ſhe does it directly down, inſtead of yerking backwards, ſhe is ſaid to *ſlime*; and if it be in drops, it is called *dropping*. When ſhe, as it were, ſneezes, it is called *ſniting*. When ſhe raiſes and ſhakes herſelf, ſhe is ſaid to *rouſe*. When after mantling ſhe croſſes her wings together over her back, ſhe is ſaid to *warble*.

When a hawk ſeizes, ſhe is ſaid to *bind*. When, after ſeizing, ſhe pulls off the feathers, ſhe is ſaid to *plume*. When ſhe raiſes a fowl aloft, and at length deſcends with it to the ground, it is called *truſſing*. When, being aloft, ſhe deſcends to ſtrike her prey, it is called *ſtooping*. When ſhe flies out too far from the game, ſhe is ſaid to *rake*. When, forſaking her proper game, ſhe flies at pyes, crows, &c., that chance to croſs her, it is called a *check*. When, miſſing the fowl, ſhe betakes herſelf to the next check, ſhe is ſaid to *fly on head*. The fowl or game ſhe flies at is called the *quarry*. The dead body of a fowl, killed by the hawk, is called a *pelt*. When ſhe flies away with the quarry, ſhe is ſaid to *carry*. When, in ſtooping, ſhe turns two or three times on the wing, to recover herſelf before ſhe ſeizes, it is called *cancelliering*. When ſhe hits the prey, yet does not truſs it, it is called *ruff*. The making a hawk tame and gentle, is called *reclaiming*. The bringing her to endure company, *manning* her. An old ſtaunch hawk, uſed to fly and ſet example to a young one, is called a *make hawk*.

The reclaiming, manning, and bringing up a hawk to the ſport, are not eaſily brought to any preciſe ſet of rules. They conſiſt in a number of little practices and obſervances, calculated to familiarize the falconer to his bird, to procure the love thereof, &c. The principal hold and foundation which the falconer has to work upon, is the bird's ſtomach. This great principle of appetite he is to make uſe of a hundred ways, to lead the bird obliquely to what he would have from her: all he can do is, to divert nature, and make her ſubſervient to his purpoſes, to make it the intereſt of the bird, either real or apparent, to do what the falconer requires of her. The courſe, it is evident, will be different, according to the ſtate and condition of the bird to be managed. An *eyeſs*, *e. g.* needs no reclaiming; ſhe is to be carefully nurſed and brought up in her natural tameneſs.

A *brancher*, *ſoar-hawk*, or *ramage-hawk*, needs no nurſing; ſhe is to be brought down from her wildneſs, and habituated to another courſe of life; and in purſuance of her own views and intereſts, ſhe is to be made ſubject to thoſe of her maſter.

To reclaim, *e. g.* a *haggard-falcon*, they begin with ſhutting her up from the light, by pulling a hood over her eyes and fixing her by a *creanſe*, which makes her more acceſſible.

The next thing is to handle her frequently; taking her up, often ſtroaking her, ſetting her on the hand, and carrying her about; unhooding, and preſently hooding her again; and this for eight or nine days, without ever ſuffering her to ſleep.

All the while ſhe is to be kept ſharp ſet, but to be frequently fed with a little at a time, unhooding her for the purpoſe; and, when unhooded, the voice is to be continually uſed to her, that ſhe may learn it; and that the hearing of the voice may naturally put her in hopes of being fed. This done, ſhe is to be invited to come from the perch to the fiſt, by unſtriking her hood, ſhewing her ſome meat, uſing the voice, and calling her till ſhe come to it, and feed thereon. If ſhe ſtill refuſe, keep her ſharp ſet till ſhe will do it. Proceed then to bring her to the lure, by giving her to ſome perſon to hold, and calling her with a lure, well garniſhed with meat on both ſides, and give her a bit: uſe her to this for ſix or ſeven days; after which, tempt her to come gradually farther and farther off to the lure, waving it, and caſting it round your head, &c. and if ſhe comes to it roundly, reward her: in three or four days more call her to your lure, well garniſhed as above, as far as it is poſſible for her to ſee or hear you; and ſet her looſe from all her furniture.

The hawk thus manned, reclaimed, and lured, you may go with her into the fields, and whiſtle her off your fiſt, to ſee whether ſhe will take out, or not: if ſhe mount and fly round you in circles, as a good hawk ought to do, after two or three turns call to her with your voice, and fling out the lure about your head, and upon her ſtooping or coming to it, give her a chicken, or pigeon, and let her kill and feed thereon. Being thus far initiated, give her firſt ſtones every evening, to prepare her body for caſtings; and then caſtings, to cleanſe and ſcour her body, and make her eager. This courſe continue, till ſhe have endowed and muted enough to enter upon buſineſs.

If the hawk be intended for ſome particular ſort of game, let her lure be a reſemblance of that ſort of game; and make a practice of frequently feeding and rewarding her thereon, or on a train of the ſame kind; calling her, when feeding, as if ſhe were called to the lure. Add, that it may be proper to feed her in ſuch ſorts of places as thoſe her game is chiefly to be found in.

To *enter a hawk*, it may be convenient to take a well-quarried hawk, and let her ſtoop a fowl, on brook or plaſh; this done, reward, hood, and ſet her; and taking the young hawk, go half a bow-ſhot up the wind, looſe her hood, and ſoftly whiſtle her off the fiſt, till ſhe have roufed, or muted; then let her fly with her head into the wind, and when ſhe is at a proper height, let go a fowl for her to ſtoop and truſs. See FALCONRY.

HAWKINS, *Sir* JOHN, in *Biography*, a ſucceſsful naval commander, was born at Plymouth in 1520. While very young he made ſeveral voyages to Spain, Portugal, and the Canaries, and being an obſervant and very intelligent youth, he acquired a fund of knowledge both maritime and commercial. He is ſaid to have been the firſt perſon who ſet on foot the infamous traffic in ſlaves, which at that period does not ſeem to have militated againſt the feelings of the moſt enlightened and humane of our countrymen. He fitted out a ſmall ſquadron, aſſiſted by ſeveral merchants, with which he ſailed to the coaſt of Guinea, where, partly by money, but chiefly by force, he obtained a cargo of three hundred blacks, whom he carried to Hiſpaniola, and ſold in a contraband traffic. Succeſs in one inſtance induced him to continue the ſame piratical, and kidnapping trade, which, to the honour of our country, has been now aboliſhed with all the indignation it merited. It is the apology of our commander, that ſo far from its being regarded as a ſtain on his humanity, he even bore the badge of theſe exploits in a creſt

of arms granted him by patent, conſiſting of a "demi-moor in his proper colour, bound with a cord." In returning from a third expedition of this kind he was attacked and defeated by a Spaniſh fleet. After undergoing many hardſhips, he reached home in Jan. 1568; and, it is ſaid, that his ill-ſucceſs, in this inſtance, damped his ardour for maritime enterpriſe, which he reſigned to younger men, many of whom, particularly the renowned Drake, his kinſman, had been brought up under himſelf. In 1573 he was appointed treaſurer of the navy, and in a few months he had nearly loſt his life, by a wound from an enthuſiaſtical aſſaſſin, who miſtook him for another perſon. He was now conſulted on every important occaſion, and, in 1588, was appointed rear-admiral on board the Victory, to confront the famous ARMADA (which ſee). His conduct on this occaſion, obtained for him the high commendations of his illuſtrious queen, the honour of knighthood, and other important commands in the navy. He died in 1595, it is ſaid, of vexation, on account of an unſucceſsful attempt on the enemies poſſeſſions in the Weſt Indies, and in the Canaries. He was a good mathematician, and underſtood every thing that related to his profeſſion as a ſeaman. He poſſeſſed much perſonal courage, and had a preſence of mind that ſet him above fear, and which enabled him frequently to deliver himſelf, and others, out of the reach of the moſt imminent dangers: he had great ſagacity, and formed his plans ſo judiciouſly, and executed the orders committed to him with ſo much punctuality and accuracy, that he ever obtained the applauſe of his ſuperiors. He was ſubmiſſive to thoſe above him, and courteous to his inferiors, extremely affable to his ſeamen, and much beloved by them. He ſat twice in parliament as burgeſs for Plymouth, and once for ſome other borough. He erected an hoſpital at Chatham for the relief of diſabled and diſeaſed ſeamen, and is highly applauded by his contemporaries, and by hiſtorians, who lived after him. Mr. Evelyn, in his diſcourſe on medals, mentions his name with thoſe of others, moſt reſpectfully: "I go on," ſays he, "to enquire, but without much ſatisfaction, I confeſs, what medals were ſtamped from the reign and revolutions of our ſeventh and eighth Henries' time, to almoſt this age of our's. Had ſuch actions and events happened among the reſt of the poliſhed world, we ſhould not be now to ſeek for the heads of ſir Francis Drake, Cavendiſh, Hawkins, Frobiſher, Greenvil, Fenton, Willoughby, and the reſt of the Engliſh argonauts; and ſurely they that firſt encircled this globe of earth and ſea, might, at leaſt, be thought worthy the honour of a copper medal, which yet I no where find." Like the writers of the Biographia Britannica, to which the reader is referred for more particulars, we by this article endeavour to ſupply the want of a medal.

HAWKINS, *Sir* RICHARD, ſon of the preceding, was brought up to a maritime life, and in 1582, when very young, he had the command of a veſſel, in an expedition, under his uncle, to the Weſt Indies: he alſo commanded a ſhip in the action againſt the Spaniſh Armada, in which he was greatly diſtinguiſhed. About the year 1593, he ſailed with three ſhips, his own property, to the coaſt of Brazil, at the commencement of a much longer voyage; but he was obliged to burn one of his little ſquadron, another deſerted their commander, ſo that he was under the neceſſity of ſailing alone through the ſtraits of Magellan. To ſatisfy the deſires of his men, he made prizes of ſome veſſels, which drew upon him the whole force of a Spaniſh ſquadron, to which he was compelled to yield. After a confinement of two years in Peru and the adjacent provinces, he was ſent back to Europe. He died in 1622, as he was attending, on buſineſs, the privy council. He left behind him a work of conſiderable value, which was printed and ready for publication; it is entitled "The Obſervations of ſir Richard Hawkins, knight, into the ſouth-ſea, A. D. 1593." From this piece, which the author dedicated to prince Charles, afterwards king Charles I., it appears that the iſſue of his voyage to the South-ſeas, his long confinement, and the diſaſters which naturally attended it, brought him into great diſtreſs. His nautical obſervations; his deſcription of the paſſage through the Straits of Magellan, and his remarks on the ſea-ſcurvy, and on the beſt methods of preſerving his men in health, were conſidered, at that period, of very great importance. He intended to have publiſhed a ſecond part of his Obſervations, in which he meant to have given an account of what happened to him and his companions, during their ſtay in Peru, and in Terra Firma, but which death prevented him from accompliſhing. It has been ſaid of ſir John and ſir Richard Hawkins by an eminent writer, "Had fortune been as propitious to them both, as their virtue, valour, and knowledge were eminent; they might have equalled the choiceſt worthies of any age." Biog. Brit.

HAWKINS, in *Geography*, a county of America, in Waſhington county, Teneſſee, watered by the Holſton and Clinch rivers, bounded N. by Virginia, E. by Waſhington and Sullivan counties, and containing 6563 inhabitants, including 811 ſlaves. Its chief town is Rogerſville.

HAWKINS *Iſland*, an iſland in the E. part of Prince William's ſound, above 20 miles in length, from S. W. to N.E. and from one to five in breadth. N. lat. 60° 28', to 60° 40'. E. long. 214° 10', to 214° 38'.

HAWKSHEAD, a market-town in the hundred of Lonſdale and county of Lancaſter, England, is ſituated in a vale near the lake of Eſtwaite, at the northern extremity of this county, where it projects between thoſe of Weſtmoreland and Cumberland. Being the principal town of the diſtrict called Furneſs-Fells, Hawkſhead is the centre where all the buſineſs is tranſacted, and the produce diſpoſed of: and though it has no ſtaple manufacture, or trade, yet, from the concurrence of local circumſtances, it has a conſiderable market, held on Monday, by a charter granted by James I. who, by the ſame grant, eſtabliſhed four annual fairs. The church, which was formerly a chapel under Dalton, was made parochial towards the cloſe of the ſixteenth century, by Dr. Edwin Sandys, archbiſhop of York, who was a native of this town; he alſo founded a free grammar-ſchool here, and endowed it with a revenue of 30*l.* per annum, which is now increaſed to upwards of 100*l.* One hundred boys are educated in this ſchool, which is held in high eſtimation. A neat town-houſe was lately built by ſubſcription, towards which ſeveral merchants of London, who had received their education in this ſchool, were the chief contributors. At Gallow-barrow, an adjoining village, is a charity-ſchool, endowed in 1717, by the will of the Rev. Thomas Sandys, curate of St. Martin-in-the-Fields, London, for the maintenance of poor boys born in this town, who are to be educated in the free-ſchool. Hawkſhead, in 1801, contained 160 houſes and 634 inhabitants. Near this town are the remains of a houſe where one or more monks, as repreſentative of the abbot of Furneſs, reſided, and performed divine ſervice and other parochial duties; over the gateway is a court-room where the abbot's temporal rights and juriſdictions were exerciſed by the bailiff of Hawkſhead. Cloſe's "Antiquities, &c. of Furneſs," 8vo.

HAWLBOULING, a ſmall iſland in the harbour of Cork, nearly oppoſite to the town of Cove, on which there has long been a ſmall fort, and which has lately been fixed upon as a naval depôt for ſupplying the men of war and other

other veſſels on the Iriſh ſtation with every kind of neceſſary. Large warehouſes have been built, and other works are in contemplation.

HAWLEY, a townſhip of America, in Hampſhire county, Maſſachuſetts, 120 miles W. of Boſton; containing 878 inhabitants.

HAWLING WAY, is the ſame with TOWING-*path*, which ſee.

HAWSE, or HAUSE, denotes the ſituation of the cable before the ſhip's ſtem, when ſhe is moored with two anchors out from forward; *viz.* one on the ſtarboard, and the other on the larboard bow. *Hawſe* denotes alſo any ſmall diſtance a-head of a ſhip, or between her head and the anchors employed to ride her.

HAWSE, *Burning in the*, is when the cable endures an extraordinary ſtreſs.

HAWSE, *Bold*, is when the holes are high above the water.

HAWSE, *Clearing the*, is untwiſting of two cables, which being let out at different hawſes, are entangled or twiſted about one another, or directing the cables to their anchors, without lying athwart the ſtern.

HAWSE, *Foul*, implies that the cables lie acroſs the ſtern, or bear upon each other, ſo as to be rubbed or chafed by the motion of the veſſel.

HAWSE-*full*, or *to ride hawſe-full*, at ſea. See RIDE.

HAWSE, *Freſh the*. When there is reaſon to ſuſpect the cable may be fretted in thoſe holes, they veer out a little, to let another part endure the ſtreſs. This they call to *freſh the hawſe*.

Freſhing the hawſe is alſo uſed when new pieces are laid upon the cable in the hawſe.

HAWSE, *Riding upon the*, is when any weighty ſubſtance lies acroſs, or falls directly before the hawſe.

HAWSE-*pieces*, denote the foremoſt timbers of a ſhip, whoſe lower ends reſt upon the knuckle-timber, or the foremoſt of the cant timbers. They are generally parallel to the ſtem, having their upper ends ſometimes terminated by the lower part of the beak-head; and otherwiſe, by the top of the bow, particularly in ſmall ſhips and merchantmen.

HAWSES, or *Hawſe-holes*, are two round holes under her head, through which the cables paſs when ſhe lies at anchor.

HAWSER, or HALSER, belonging to a ſhip, is a rope conſiſting of three ſtrands; being a kind of little cable, ſerving for many uſes on board; as to faſten the main and fore ſhrouds, to warp a ſhip over a bar, &c.

HAW'S WATER, in *Geography*, a lake of England, in the county of Weſtmoreland.

HAWTHORN, or HAW, in *Botany*. See CRATÆGUS.

HAWTHORN, the common name of the thorn plant, which is uſually employed in the forming of new hedge-fences. It is, likewiſe, ſometimes denominated the white thorn. See FENCE.

HAWTHORN, *Black American*. See VIBURNUM.

HAY, in *Agriculture*, a term generally applied to any ſort of graſs that is cut by the ſcythe, and dried in the ſun, ſo as to be preſerved as a fodder for any kind of live-ſtock. The varieties of hay are very different according to the nature of the land from which they are produced, and the deſcriptions of graſs from which they are made. Thus we have upland, orchard, and meadow hay as well as clover, ſainfoin, lucern, rye-graſs, tare, and other ſorts of artificial graſs hay. It is alſo ſometimes further diſtinguiſhed into dry hay, or that which is raiſed from the uplands; and into rouen or after-graſs hay, which is that made from the ſecond cut of graſs in ſome ſituations.

It is ſufficiently evident that hay muſt be poſſeſſed of very different properties and qualities, according to the nature and ſituation of the land from which it is cut, as well as the peculiarities of the graſſes, conſequently, capable of being applied to different purpoſes of feeding and fattening various ſorts of domeſtic animals.

That ſort of hay which is derived from the higher grounds, and that which is prepared from the different ſorts of artificial graſs crops, are ſuppoſed in general to be the moſt beneficial in the foddering of team-horſes, and labouring cattle ſtock of different kinds, as affording to them a more durable and permanent kind of nouriſhment, as well as giving them greater power and better wind. But the low meadow, marſh, orchard, and ſome other of the ſofter deſcriptions of hay, are, from their poſſeſſing ſuch qualities, better ſuited as a fodder for milch cows, and other kinds of neat-cattle, as well as ſuch horſes as are not much employed in team labour. The rouen or after-graſs hay, as poſſeſſing a ſtill more ſoft quality, is the beſt ſuited as a food for ſheep and lambs in the winter and early ſpring ſeaſons. In thoſe ſituations where lamb-ſuckling is had recourſe to, the greeneſt, and that which retains the largeſt proportion of juicy material, is invariably made uſe of as a fodder for the ſuckling ewes. It may, likewiſe, be employed for milch cows with advantage in moſt caſes.

All the ſorts of hay are in general much too expenſive to be uſed with advantage as a fodder for ſtore ſtock, except in mixture with ſome kind of ſtraw.

In the diſpoſal of hay many different methods are followed, but which are generally regulated by the peculiar cuſtoms of the different places and markets. The ſtone, yard, and load, are, however, by far the moſt common. The laſt is that which prevails in the markets of the metropolis, and the hay is univerſally bound up into what are termed truſſes, which ſhould weigh fifty-ſix pounds, thirty-ſix of which conſtitute a load, being in the whole about eighteen hundred weight, when the hay is taken from the ſtack; but when taken from the field, or at a ſhort period after being put into the ſtack, twenty hundred weight is commonly conſidered as the quantity for the load.

The beſt hay is generally that which is made in due ſeaſon, and without any rain falling upon it.

HAY, in *Rural Economy*, a term frequently made uſe of, in particular diſtricts, to ſignify a clipped hedge.

HAY-*band*, a ſort of twiſted rope, formed from the more coarſe and long hay, and which is made uſe of for the purpoſes of binding up the truſſes, in order to the hay being ſold in ſome places. From the above kind of outſide hay being employed, there is but little loſs ſuſtained in this cuſtom of binding hay in truſſes. This practice prevails on all the London markets. See TRUSS.

HAY-*barn*, a name applied to that ſort of barn which is conſtructed for the particular purpoſes of containing hay. Barns of this deſcription are for the moſt part formed of wood in a very open manner at the upper parts in order that air may be admitted with freedom. They are conſtantly without any ſort of bays in them. It has been ſtated in the Survey of Middleſex, that in the vicinity of Harrow, Hendon, and Finchley, in that diſtrict, there are many hay-barns capable of holding from thirty to fifty, and ſome even a hundred loads of hay, and that they are found to be extremely beneficial and convenient in ſuch hay-ſeaſons as are catching and unſettled, as well as in other caſes, in conſequence of the ſtate of the weather. In the very uſual caſe of rain approaching, where the hay is ready to be carried, it

it is common to exert every nerve in order to ſecure as much as poſſible, which, without doubt, is beſt effected by having all the carts loaded and drawn into the barns, unloading them as quickly as poſſible on to the mows, being there left in the graſs until a more leiſure period offers for ſpreading the hay out; as many of the carts as the time and ſtate of the weather will admit of being again loaded, and drawn a ſecond time into the barns on rain falling when thus ſecured no danger need be apprehended; as by merely ſhutting the doors, the hay is completely preſerved againſt all ſorts of moiſture. Where the weather continues improper for other buſineſs, the carts that are loaded in the barns can be conveniently emptied upon the mows, and the laſt properly trimmed and put into order by the workmen, who would otherwiſe be, perhaps, unemployed. Beſides, ſuch barns at other periods of the year, afford the means of cutting and truſſing the hay for the market or otherwiſe, operations which could not be executed at ſuch periods out of doors where the hay is in ſtacks.

It is ſtated that the farmers there contend that the hay may be put together earlier even by a day, where barns are employed, than it would be ſafe to have the work done under the ſtacking ſyſtem. But they recommend that the ſides of the mows ſhould be pulled ſo as to become perfectly clear of the quarterings of the barns. In this management they are of opinion, that the hay will be as good in the barns as in the ſtacks. And it is further ſuggeſted, on experience, that "in the *drieſt ſeaſons*, barns are a ſaving of four or five ſhillings an acre, and in *wet* ſeaſons, the ready aſſiſtance which they afford in ſpeedily ſecuring the hay, has been known to make a difference of *twenty ſhillings* a load, on a ſmall number of loads." The increaſing expence of ſtraw likewiſe renders theſe kinds of buildings ſtill more deſirable. In many of the more northern diſtricts, but little of the hay is placed in ſtacks in the open air; but in the ſouthern hay diſtricts, notwithſtanding the above, it is hinted that many ſuppoſe "that hay put into barns is apt to be duſty on the ſides next the boards; and that, from the ſmallneſs of the quantity put together, it has too much outſide, and is conſequently ſubject to be over dry. That in this caſe it ſhould be ſold before Lady-day." It is, however, ſuggeſted by the author of the Survey of Middleſex, that theſe objections "are in a great meaſure unfounded. The ſecond can certainly only happen where the barns are too ſmall; and as to the others, he can anſwer that he has had three barns at a time full of hay: the boards and quarterings were ſwept clean immediately before depoſiting it; they were filled completely; and he had the hay trodden down as much as poſſible. The ſides of the mows were neither raked nor pulled, as he was of opinion that ſuch a meaſure would be an unneceſſary loſs of room. When this hay came to be bound out, the whole was found to be perfectly free from duſt, of good ſmell and colour, and ſold at as high a price as the beſt hay from the ſtack-yard. The ſmell of ſuch of the hay as lay againſt the weather boarding, muſt however be excepted, on the ſhady ſides of the barn, but even that was confined to the ſurface; it was without duſt, and no way injured in its colour. It was all made without receiving any rain, and that which was the leaſt prepared was put into the barns." The ſtacking of hay in the open air is, however, the practice which is the moſt predominant in the whole of the vicinity of the metropolis, where probably the beſt hay in the kingdom is met with. See BARN.

HAY-*binder*, a name applied to the perſon who is employed in binding up hay into truſſes for the market. Work of this ſort is moſtly performed by the load, the price of which varies conſiderably, being in ſome places 2*s*. in others, 2*s*. 6*d*. and occaſionally 3*s*. or more.

HAY-*binding*, the art or practice of tying up hay into truſſes of equal weights. This is a ſort of farm work, at which the labourer is capable of making much better wages than in moſt other kinds, and this alſo at a ſeaſon when other ſorts of workmen generally get the leaſt, as in the winter months. There are, however, not many that turn themſelves to this ſort of employment, and ſtill fewer who are capable of executing it in a proper manner. Such workmen as are expert in the buſineſs, are capable of judging by the appearance of the truſs, and the balancing of it in the hand, when it is of proper weight, frequently without having the neceſſity of making uſe of the ſteel yards; conſequently when they have opened their ſtacks, and cut out a few loads from the top, which is conſtantly the leaſt weighty, the work proceeds with great diſpatch, one perſon being employed in cutting, and the other in binding up the truſſes. It is beſt, however, conſtantly to weigh the truſſes. In caſes where the hay is good, and has ſuffered no injury from wet, or from heating in the ſtack, there is ſcarcely a particle loſt in the binding. The looſe locks are put in the middle of the truſs, ſo that it may have the more ſightly appearance on the outward ſurface; and the bands are made with the hay, there being a penalty inflicted by the act of parliament on the uſe of ſtraw bands. It is invariably the cuſtom for the binder to find the ſteel-yards, and the other implements that are required in performing the work.

The practice of binding hay is ſo neat, convenient, and economical a plan, that it ſhould be much more generally had recourſe to by farmers. See HAY.

HAY-*bote*, an ancient term applied to a ſort of feudal right, by which a tenant for life, or a term of years, has a liberty of taking buſhes, wood, &c. for the repairing of fences, gates, and other ſimilar uſes. It likewiſe ſignifies the liberty of cutting wood for making rake and fork handles, which are uſed in making hay and other fodder for cattle.

HAY-*brining*, or *Salting of*, the mode of ſprinkling hay with ſalt, in order to make it keep better, and render it more freely eaten by live ſtock. See SALTING *of Hay*.

HAY-*fork*, the name of the ſmall fork which is uſed in making hay, and pitching it to the cart, mow, ſtack, &c. In the firſt of theſe intentions the tines or prongs need not have any great length, but in the latter they ſhould have conſiderable length, and have a gentle curving inclination forward, in order that the hay may be taken up and held more perfectly by them.

HAY, *Burgundian*. See MEDICAGO.

HAY-*knife*, the name of a ſharp inſtrument made uſe of in cutting hay out of the ſtack or mow. This tool ſhould conſtantly be kept perfectly free from ruſt, and as ſharp as poſſible. An improvement is aſſerted to have been made in this implement by having it conſtructed in ſome manner in the form of the common garden ſpade, the edges being well ſteeled and rendered perfectly ſharp. In uſing this inſtrument, the workman cuts directly downwards, inſtead of that of the oblique direction, as is the caſe in employing the old tool.

HAY, *Laying up of*, the art of putting hay together in ſtacks, mows, or other forms, ſo as to preſerve it for future uſe. See STACKING *of Hay*, and STACK.

HAY-*maker*, a labourer or any other perſon who is employed in the work of converting cut graſs into hay. Such perſons as are engaged in this ſort of buſineſs, ſhould conſtantly, in order to execute it in a proper manner, be perfectly

fectly acquainted with the various operations and proceſſes which are neceſſary to be had recourſe to, ſuch as thoſe of ſpreading out, raking, tedding, turning, cocking, &c.; as where labourers who are unacquainted with theſe are provided, the proprietor muſt conſtantly ſuſtain great diſadvantage in conſequence of ſuch operations being performed in an improper manner. Beſides, there is much loſs in the quantity of work that is done.

It has been ſtated, that in Middleſex, as ſoon as the graſs appears nearly in a proper condition for being cut down, the farmers endeavour to procure the beſt mowers that can be had, in number proportioned to the extent of the crops, and the length of time they ſhould be under hand, after which, they are let out to be mown by the acre as piece work; each mower cutting from an acre and a half, to an acre and three quarters per day; and there are ſome who are capable of mowing two acres per day through the whole of the ſeaſon. It is uſual for theſe labourers to begin their work at three, four, or five o'clock in the morning, and continue their work till ſeven or eight at night, reſting an hour or two in the middle of the day, while the power of the ſun is the moſt conſiderable.

About the ſame period, five haymakers, conſiſting generally of a mixture of men and women, including loaders, pitchers, ſtackers, &c. are provided. Theſe are commonly paid by the day, the men attending from ſix in the morning to the ſame hour in the evening, but the women only from about eight in the morning to ſix in the evening. It is uſual for any extra diſpatch, for them to receive an additional allowance.

It is the univerſal cuſtom, that each hay-maker ſhould come provided with a fork, and moſtly a rake of his own; but it occaſionally happens when much of the graſs is ready, and labourers are ſcarce, that the farmer is under the neceſſity of providing both, though more generally the rake only. In the execution of the work, every part is carried on by means of forks, except that of clearing the ground, which is of courſe performed by rakes, and the loading the carts, which is done by hand labour. See HAY-*making*.

HAY-*making*, the art or operations by which cut graſs is converted into the ſtate of hay. In the execution of this kind of buſineſs, it is conſtantly neceſſary to have a regard to the nature of the graſs, the ſtate of the ſeaſon, and the ſituation of the ground on which it is grown. It is obvious that, in all deſcriptions of ſeaſons, ſuch graſs crops as are of the more dry and leſs juicy kinds, and where the expoſures are high and open, will require much leſs time in the proceſs of forming them into hay, than under the contrary circumſtances.

As hay is an article of food, which is not only of great conſequence to the farmer, from its being one of the principal products of land, as well as the chief fodder of moſt ſorts of live ſtock, but as that upon which their health and condition very greatly depends, it is natural to ſuppoſe that under ſuch circumſtances, experiments would have been made, and a proper attention have been beſtowed, in order to introduce a regular ſyſtem of management. But it muſt be confeſſed, that in various diſtricts of the kingdom, not any attention of this ſort has been paid to the ſubject, and that the mode of management, particularly in ſeveral of the more northern parts, is indeed extremely ſlovenly, and very badly calculated to preſerve and ſecure in the beſt ſtate of perfection, that flavour, and thoſe qualities which are indiſpenſible, in order to render hay and every other ſort of dried herbage valuable as cattle fodders.

It is ſuggeſted in an uſeful and periodical work upon this ſubject, that "the firſt conſideration in the treatment of hay is, the period at which the graſs ſhould be cut, and the weather moſt proper for that operation." And that, as "the time moſt proper for cutting the different kinds of grain, together with every ſtep of the after-management, are points well underſtood, and for the moſt part ſtrictly obſerved; every farmer, being ſenſible that any neglect of, or deviation from theſe rules will, by impairing the quality of both the grain and ſtraw, be productive of much trouble and loſs to himſelf, it is ſomewhat extraordinary, that the ſame kind of reaſoning ſhould not have been applied to the management of hay; as any diminution of its value, ariſing from improper treatment, muſt be equally prejudicial both to the grower and conſumer of that article, as to the grower and conſumer of grain."

It is ſtated that "the practice of many farmers in North Britain is to allow their hay, not only to attain its ultimate growth, but even to make ſome progreſs towards decay, before it is cut: To obtain a bulky crop being their chief object, every other conſideration is diſregarded; and neither the period of growth at which the cutting ought to commence, the weather moſt proper for that operation, nor indeed any ſtep of the after-management, are regulated by fixed rules. In place of cutting the crop during dry weather, and when it is free from every other but its own natural moiſture, it is very often cut in a wet ſtate, and on that account muſt remain in the ſwath a conſiderable time before it is fit for being put into cocks; during which, it requires to be frequently turned and expoſed to the ſun and atmoſphere, for the purpoſe of drying it: in that way, a conſiderable proportion of its natural juices is diſſipated; and, by the time it is dry enough for putting into the ſtack, it has loſt not only its flavour, but a great part of its moſt valuable properties; an evil that is farther increaſed, if much rain happen to fall either immediately after the cutting, or at any period before it is put into cocks: in that caſe, a ſtill greater loſs of its nouriſhing properties, and a conſequent diminution of its value, muſt happen." Hence "the conſequences of this management are felt in a variety of ſhapes, in every diſtrict where it prevails. In the lower diſtricts, the miſchief is comparatively ſmall, owing to the mildneſs of the winters, the great quantity of rich foggage every where to be met with, and the abundance of corn-ſtraw, and other wholeſome articles of food, with which theſe parts abound.

"In the hilly and upland diſtricts, however, the caſe is very different; and the loſs ariſing from the neglect and miſmanagement of their hay is great, almoſt beyond calculation. In theſe elevated regions, the winters are, for the moſt part, of uncommon length and ſeverity; little ſtraw is produced; ſown graſſes, turnips, and potatoes, are equally ſcarce. In that way, the chief dependence of the farmer, for winter-food to his ſtock, falls upon the hay, which, when the quality is bad, and other articles ſcarce, induces debility and diſeaſe to ſuch a degree, that a great part of the ſtock either die, or are reduced to a ſtate of extreme weakneſs during the winter; and when the ſpring arrives, the green food has ſuch an effect upon the bowels of thoſe who have ſurvived, that many of them die alſo." Further, "the greateſt part of the hay grown in theſe parts is the produce of the wet ſwampy grounds, and the plants, of which it conſiſts, are of a nature that requires much judgment and attention to cure, in ſuch a manner, as to unite every advantage that might be expected from their uſe." In reſpect to the period moſt proper for cutting hay, "experience proves, that the greateſt perfection of the herbage is met with, either immediately before it comes into flower, or as ſoon as the firſt flowers

flowers blow. At that period, it is in no ſhape exhauſted, either by blowing a multitude of flowers, or forming ſeeds, and contains all the uſeful qualities of which its nature is capable. After that period, it daily diminiſhes in value, becomes tough, ſapleſs, and unpalatable, and is not chewed without conſiderable difficulty. This rule applies to every ſpecies of herbage that is meant to be dried for winter food; but to coarſe hay, the produce of wet or marſhy grounds, it is ſtrongly applicable; for moſt of the plants which grow in theſe ſituations, when they are in full vigour, are as tender, and contain perhaps as great a proportion of nouriſhing juices, as any other deſcription of hay; and, when cut at that ſtage, and properly managed afterwards, form a valuable article of food both for ſheep and cattle; but when the cutting is delayed, as indeed it very often is, till an advanced period of the ſeaſon, when the plants have not only reached their ultimate growth, but begin to decay, this deſcription of herbage becomes at once the coarſeſt and leaſt nouriſhing of all food." And it is contended, that, "this opinion does not proceed upon theory, but upon the ſolid ground of experiments carefully made upon many different kinds of herbage, at different periods of their growth, the reſult of which eſtabliſhes a fact that cannot be too generally known, *viz.* that plants of all ſorts, if they are cut when in full vigour, and afterwards carefully dried, without any waſte of their natural juices, either by bleaching with rain, or exhalation, contain, weight for weight, a quantity of nouriſhing matter nearly double what they do, when allowed to attain their full growth, and make ſome progreſs towards decay." It is conſequently concluded, that graſs "of all kinds ſhould certainly be cut at the period mentioned, and, if poſſible, during dry weather."

In further confirmation of the truth of this opinion, it is ſtated in the Survey of Perthſhire, that, "as the great object in making hay is that of preſerving as much of the natural ſap as poſſible, the proper time for cutting is, when the crop of graſs has attained its higheſt degree of perfection; when the plants are in full blow, and before their flowers begin to fade. If cut too green, the hay ſhrivels and loſes much of its bulk; if allowed to ſtand till the ſeeds are ripe, the ſtem becomes hard and wiry, the roots loſe much of their natural ſap, the aftermath is leſs abundant, and the principal part of the hay is in danger of crumbling away into ſhort ſtumps, under the various operations which it muſt undergo. Better to be too ſoon than too late; eſpecially if the crop be heavy and in danger of lodging."

And with clover, that "the beſt time for cutting it is, when the flowers are all fully blown, and the earlieſt begin to turn brown. If allowed to ſtand longer, the roots of the ſtalks loſe their leaves, and become hard and ſticky; and the plant is ſo much exhauſted, that it takes a long time before it ſend up new ſhoots." See CLOVER.

Hence it is clear, that in converting cut graſs into hay, the great art conſiſts in rendering it ſufficiently dry to prevent its taking on too great a degree of heat in the ſtack or mow, and at the ſame time preſerving as great a portion of the natural juices of the plants, as the proceſs is capable of admitting of without danger. Where this medium can be attained in the moſt exact manner, the beſt and moſt nutritious hay will be produced; but it is a point of great difficulty, and which requires a great deal of care and attention in order to its attainment; the great danger in fine ſeaſons being that of not making it in a ſufficient manner, while in thoſe of the contrary deſcription, it is liable to be made in too high a degree, as is abundantly ſhown by the inconveniences which are often ſuſtained from the heating of the ricks in the former caſes, while it is ſeldom or never experienced in the latter.

It has been uſefully ſuggeſted in the excellent Survey of the County of Middleſex, after noticing the advantages of attending to the properties of the ſoil and the herbage it affords, in the proceſs of making hay, that "the hard benty hay of a poor ſoil, as it is in little or no danger of heating too much in the ſtack, ſhould, therefore, be put very early together, in order to promote a conſiderable ſweating, as the only means of imparting a flavour to it, which will make it agreeable to horſes and lean cattle, as it will be nearly unfit for every other ſort of ſtock. It is the ſucculent herbage of rich land, or land highly manured, that is moſt likely to generate too great a degree of heat: of courſe, graſs from ſuch land ſhould have more time allowed in making it into hay. In moderately hot ſeaſons, the proper point of drying may be eaſily judged of; but when they are very hot and ſcorching, it is eaſy to be miſtaken; as, in ſuch weather, the graſs becomes criſp, ruſtles, and handles like hay, before the moiſture or ſap is ſufficiently diſſipated for it to be in a ſtate fit to be laid up in large ſtacks. If that, however, be done when it is thus inſufficiently made, it moſtly heats too much, becoming mow-burnt in ſome caſes." And further that another point, which is often of much difficulty in the execution, but of much conſequence, is that of "carrying the whole of the hay juſt at the moment it is ſufficiently made; which is neceſſary, in order to its yielding the greateſt poſſible weight, and preſerving its beſt quality; as every minute after that preciſe time it continues to loſe, both in weight and in its nutritious properties, by evaporation." Even the difference of an hour, in a very hot drying day, is ſuppoſed to occaſion a loſs of 15 or 20 per cent. on the hay, by its being carried beyond the point of perfection, and frequently even a greater loſs is ſuſtained."

It is ſtated in the ſame intelligent work, that this branch of the rural art has, by the farmers of that county, been brought to a degree of perfection altogether unequalled by any other part of the kingdom. The neat huſbandry, and ſuperior ſkill and management, that are ſo much, and juſtly, admired in the *arable* farmers of the beſt cultivated diſtricts, may, with equal juſtice and propriety, be ſaid to belong, in a very eminent degree, to the hay-farmers of Middleſex: for, by them, may very fairly be claimed the merit of having reduced the art of making good hay to a regular ſyſtem; which, after having ſtood the teſt of long practice and experience, is found to be attended with the moſt deſirable ſucceſs. Even in the moſt unfavourable weather, the hay, made according to the Middleſex manner, is ſuperior to that made by any other method, under ſimilar circumſtances. It is to be regretted, that this very excellent practice has not yet, except in a very few inſtances, travelled beyond the borders of the county. But as it moſt juſtly deſerves the attention and imitation of farmers in other diſtricts, he ſhall, for their information, endeavour minutely to deſcribe the method in which the Middleſex farmers make their hay." And, "in order that the ſubject may be more clearly underſtood, he ſhall relate the particular operations of each day, during the whole proceſs, from the moment in which the mower firſt applies his ſcythe, to that in which the hay is ſecured, either in the barn or in the ſtack."

"*Firſt-day.*—All the graſs mown before nine o'clock in the morning, is tedded (or ſpread), and great care taken to ſhake it out of every lump, and to ſtrew it evenly over all the ground. Soon afterwards it is turned, with the ſame degree of care and attention; and if, from the number of hands, they are able to turn the whole again, they do ſo, or

or at leaſt as much of it as they can, till twelve or one o'clock, at which time they dine. The firſt thing to be done after dinner is, to rake it into what are called ſingle windrows, that is, they all rake in ſuch a manner, as that each perſon makes a row, which rows are three or four feet apart; and the laſt operation of this day is to put it into graſs-cocks.

"*Second day*.—The buſineſs of this day commences with tedding all the graſs that was mown the firſt day after nine o'clock, and all that was mown this day before nine o'clock. Next, the graſs-cocks are to be well ſhaken out into ſtaddles (or ſeparate plats), of five or ſix yards diameter. If the crop ſhould be ſo thin and light as to leave the ſpaces between theſe ſtaddles rather large, ſuch ſpaces muſt be immediately raked clean, and the rakings mixed with the other hay, in order to its all drying of an uniform colour. The next buſineſs is to turn the ſtaddles, and, after that, to turn the graſs, that was tedded in the firſt part of the morning, once or twice, in the manner deſcribed for the firſt day. This ſhould all be done before twelve or one o'clock, ſo that the whole may lie to dry, while the work-people are at dinner. After dinner, the firſt thing to be done is, to rake the ſtaddles into double windrows; in doing which, every two perſons rake the hay in oppoſite directions, or towards each other, and by that means form a row between them of double the ſize of a ſingle windrow. Each of theſe double windrows are about ſix or eight feet diſtant from each other; next, to rake the graſs into ſingle windrows; then the double windrows are put into baſtard-cocks; and laſtly, the ſingle windrows are put into graſs-cocks. This completes the work of the ſecond day.

"*Third day*.—The graſs mown and not ſpread on the ſecond day, and alſo that mown in the early part of this day, is firſt to be tedded in the morning; and then the graſs-cocks are to be ſpread into ſtaddles, as before, and the baſtard-cocks into ſtaddles of leſs extent. Theſe leſſer ſtaddles, though laſt ſpread, are firſt turned, then thoſe which were in graſs-cocks; and next the graſs is turned once or twice before twelve or one o'clock, when the people go to dinner as uſual. If the weather has proved ſunny and fine, the hay, which was laſt night in baſtard-cocks, will this afternoon be in a proper ſtate to be carried, as it ſeldom happens in dry weather but that it may be carried on the third day; but if the weather ſhould, on the contrary, have been cool and cloudy, no part of it probably will be fit to carry. In that caſe, the firſt thing ſet about after dinner is, to rake that which was in graſs-cocks laſt night into double windrows; then the graſs which was this morning ſpread from the ſwaths, into ſingle windrows. After this, the hay which was laſt night in baſtard cocks is made up into full-ſized cocks, and care taken to rake the hay up clean, and alſo to put the rakings upon the top of each cock. Next, the double windrows are put into baſtard cocks, and the ſingle windrows into graſs-cocks, as on the preceding days.

"*Fourth day*.—On this day the great cocks, juſt mentioned, are uſually carried before dinner. The other operations of the day are ſuch, and in the ſame order, as before deſcribed, and are continued daily until the hay-harveſt is completed."

The writer farther ſtates, that "in the courſe of haymaking, the graſs ſhould, as much as poſſible, be protected, both day and night, againſt rain and dew, by cocking. Care ſhould alſo be taken to proportion the number of haymakers to that of the mowers, ſo that there may not be more graſs in hand, at one time, than can be managed according to the foregoing proceſs. This proportion is about twenty hay-makers (of which number twelve may be women) to four mowers: the latter are ſometimes taken half a day, to aſſiſt the former. But in hot, windy, or very dry weather, a greater proportion of hay-makers will be required, than when the weather is cloudy and cool.

"It is particularly neceſſary to guard againſt ſpreading more hay than the number of hands can get into cock the ſame day, or before rain. In ſhowery and uncertain weather, the graſs may ſometimes be ſuffered to lie three, four, or even five, days in ſwath. But before it has lain long enough to become yellow (which, if ſuffered to lie long, would be the caſe), particular care ſhould be taken to turn the ſwaths with the heads of the rakes. In this ſtate it will cure ſo much in about two days, as only to require being tedded a few hours, when the weather is fine, previous to its being put together and carried. In this manner, hay may be made and ſtacked at a ſmall expence, and of a good colour; but the tops and bottoms of the graſs are inſufficiently ſeparated by it."

And the following is another method which has been adviſed for making hay in ſuch ſeaſons as are unfavourable to that buſineſs: this is, the firſt fine day that comes, to break out what graſs is cut, turn it, windrow it, and get it into ſmall cocks: the next fine day, as ſoon as the ground is dry, to break a few cocks out at a time, and keep them continually moving till they are quite dry; to put three or four of them into one cock. To proceed in this manner till they have been all broke out, and ſerved as above; and, ſhould the weather ſtill continue unfavourable for hay-making, never to venture to break thoſe cocks out again, but to take every opportunity of lightening them up with forks, to let the wind and air draw through them. This plan was purſued in the wet ſummer 1781, and by that means more good hay was made by the farmer who employed it that year, than by any perſon in the neighbourhood where he lived at the time. And he is thoroughly convinced, that graſs, cut full of ſap, is not likely to receive much damage from ſmall ſhowers of rain, till it is nearly made into hay; and, on the other hand, graſs cut when the bents are quite ripe, is liable to be damaged by every trifling ſhower that falls. When the graſs is thin, or ſtands to be quite ripe, it has been known to be only juſt broke out, raked together, cocked, and the next day put into a rick, without its being overheated, or any way injured by ſuch haſty proceedings: were they to give ſuch hay much making, it is ſuppoſed that it would never ſettle in the rick.

In "diſtricts where the hay ſeaſon is later, and the weather more changeable, it would often, it is ſuppoſed by Mr. Donaldſon, be dangerous to expoſe the hay ſo much abroad as in the firſt of the above proceſſes: a more cautious method ſhould be adopted. In ſuch caſes, inſtead of keeping the hay almoſt conſtantly ſpread out and expoſed to the atmoſphere, as in the preceding method, it may be better to put it into ſmall cocks ſoon after it has been cut down and become a little made; theſe ſhould then be frequently turned over, but not ſpread out, except when the weather is in ſuch a fine ſtate as to inſure their being put up again in the ſame ſtate, without injury from the falling of rain. But this mode is much more ſlow, though the hay is leſs expoſed to danger in wet weather, than in that; and, when there is much heat, it may be made with little trouble or expence, and without much expenditure of the nutritious juices which it contains."

However, on the Middlesex method of hay-making, Mr. Bucknall observes, that "by the regular method of tedding grass for hay, the hay will be of a more valuable quality, heat more equally in the stack, consequently not so liable to damage, or fire: will be of greater quantity, when cut into truffes, and fell at a better price; for when the grass is suffered to lie a day or two before it is tedded out of the swath, the upper surface is so dried by the sun and winds, and the interior part is not dried, but withered; so that the herbs lose much, both as to quality and quantity, which are very material circumstances, at the price hay now fetches at market. An instance in point is, the physic-gardeners, who attend to their business, are very careful in the proper and equally drying their herbs, and they find their account in it."

It is suggested in a periodical work, that, "in place of being suffered to remain in the swath for some days, as is commonly done, women, with forks or rakes, should follow the cutters, and spread it in such a manner as to allow the sun and air free access to the whole. If this operation is properly performed, and the weather favourable, the hay that was cut in the morning will be ready to be put into small cocks by mid-day, where it may remain for two or three days; and, at the end of which, if the weather is dry, they may be thrown down early in the morning, and, after being exposed to the sun and atmosphere for a few hours, put up into ricks of at least forty or fifty stones each, where it may remain with perfect safety, till it is convenient to stack it. By such treatment, every valuable quality is preserved, the hay is of a fine green colour, and possesses so agreeable a flavour, that the animals eat it with the greatest relish. Before stacking, some attention will be necessary to render the whole as uniformly dry as possible, especially if much rain has fallen, and the wind continued for any considerable time in one quarter after the hay has been put into ricks: when that is the case, one side will be found damp, while that which is exposed to the wind is perfectly dry: the remedy consists in turning the ricks round, which is done with great ease, by placing six or eight people, at equal distances, round the rick, with directions to thrust their hands as far as they can under the bottom, at the same time grasping a handful of the hay: when the whole are ready, let them lift at once, and move round in the direction intended, till the damp side is opposed to the wind: in that way ricks of fifty or sixty stones may be turned with ease and expedition, and the whole rendered uniformly dry in a short time."

From the preserving hay of a proper green colour being a point of some importance, it is necessary, in order to effect it, that the bastard-cocks, previous to their being carried, should be put up in the heat of the day, and remain in that condition till the following morning, when they may be turned and opened, so as to dispel any damp that might induce it to heat in the stack, and in that way injure the colour. It is found that the acquisition of a lightish brown colour in the stack is not injurious to hay; but where it becomes of a *dark* brown, from too much heat, it is said to weaken and relax horses that are fed upon it, by its powerful diuretic quality, consequently to be of inferior value when exposed at the market for sale.

In Yorkshire, according to Mr. Marshall's account of "the best practice of that district, the grass, in fine weather, is tedded after the mowers; or, in showery weather, as soon as a fair opportunity offers. In the evening, unless due confidence can be placed in the weather, it is put into cocklets, provincially "hipples," made in different ways; some being set up hollow with the foot and the head of the rake; others, in the common way, with forks. As the hay has advanced in dryness, the hipples are increased in size.

"Where a fair opportunity offers, and the grass is perfectly dry, the hipples are *sundered*; that is, broken out into beds in the usual manner, turned, and again got up into cocklets, of such size as the state of dryness requires. When sufficiently dry, the hay is made into well-sized cocks, namely, about eight or ten to the load.

"When the crop is intended to be stacked on the piece it grew on, the first made part generally stands in these cocks, until the whole, or the principal part of the remainder, be ready for the stack; which, by this means, is never exposed abroad in its first stage, a circumstance, however, which is too commonly suffered by less judicious hay-farmers."

But it is supposed, by a late philosophical writer, that if the swath of mown grass be turned over only *once* in the day, for three or four successive days, the interior part of it will, in a manner, be dried in the shade; and, if it were spread over the ground for a few hours in the day, the hay would become dry enough for stacking. At night the forming the grass into small cocks is advised, particularly in damp weather, in order to secure it from being injured by the slime and excrements of the very numerous worms that rise to the surface of the ground during moist warm nights. With this view, the cocks are to be made as high in proportion to their base as possible, that a small surface may come in contact with the ground, while a broader top is exposed to the air, and consequently the exhalation of moisture from the hay is promoted; while it is, at the same time, secured from accidental showers. And, in wet weather, he is of opinion that it is best to turn the swaths every day, or every second day, or to form them into small cocks, with the view of sheltering the whole from injury by long continued rains; and also of preventing the parts next the ground, as well as in the middle, from fermenting. But that when the weather is more favourable, the hay should be made into large cocks, for the more speedy exhalation of moisture by the action of the air; while an incipient fermentation will evolve or discharge a portion of heat, and thus promote the drying of the hay, by increasing the evaporation of the humid particles.

In making hay from the grass of watered meadows, Mr. Boswell directs, that a *confidential* person follow the mowers, ready to ted the grass immediately after it is cut, in which state it may remain all the first day. And, on the following morning, as soon as the dew is evaporated, it should be repeatedly turned, and formed into small cocks, the trenches and drains being raked clean out. The next day it is again tedded, and raked nearer together; the grass occupying a less space of ground in proportion as it withers: it is afterwards repeatedly turned in the course of the day, and, long before night, formed into *whales* or rows, afterwards into large cocks, and the ground again raked around them. On the succeeding day, these cocks are again spread and turned; when, if they be not sufficiently dry, they are put into still larger cocks; and, the following day they may be opened, and the grass, after being turned, carried to the stacks in the yards.

It is evident, that the expences of making hay must be liable to much variation in different situations and circumstances, in proportion as labourers are more scarce or plentiful, and as the season may be fine or the contrary. In the best

beſt hay diſtricts in the county of Middleſex, they were ſome years ſince ſtated as below:

Hay-making Expences per Acre.

	£.	s.	d.
Mowing 3s. beer 6d. - - -	0	3	6
Making and ſtacking - - -	0	9	6
Pulling the ſtack, and laying the hay pulled out upon the ſtack - - - -	0	0	6
Horſes, harneſs, and carts - - -	0	2	0
Straw for thatch 3s. thatcher and labourer 6d.	0	3	6
Total expence per acre in the ſtack-yard,	19 or 20s.		

At preſent it is more than double the ſum.

But it is obſerved, that "if the hay be put into barns, the laſt charge of 3s. 6d. will not, of courſe, be incurred; moſt of the third, and part of the ſecond, will alſo be ſaved; ſo that the whole expence in this caſe will not exceed 15s. per acre."

The nature of almoſt all ſorts of artificial graſſes, plainly ſhows, that, in making them into hay, the great object ſhould be that of preſerving their leaves or foliage as much as poſſible, as, upon this being done, much of their excellence depends. And of courſe, in order to effect it in the moſt perfect manner, a ſomewhat different practice ſhould be employed to that which is followed with the natural graſſes. After the crops have been cut down, they ſhould undergo much leſs making than with common hay, as too frequent ſtirring breaks off and diſplaces the leaves too much; by which great loſs is ſuſtained in their being left upon the ground. And as "clover begins to form its head for bloom towards the middle of June, and will continue in a growing ſtate till it becomes in full bloſſom: at which time it is in the higheſt perfection to mow for hay; and this graſs differs in this particular from ſainfoin, that when its bloſſoms are fully expanded, they continue much longer in that ſtate than that graſs; ſo that if the weather ſhould prove wet and unkindly for the haying, the clovers will wait a fortnight after they become in bloſſom without ſuſtaining any material injury, either by the ſhedding of the leaf or bloom; for the ſame weather which renders it improper to mow this graſs, continues it in a growing ſtate, and prevents the bloſſom from dying away." Therefore "where the crops of clover are large and heavy, it is neceſſary that the ſwaths ſhould be turned over at the making, the ſtalks of this graſs being very replete with juices. This may be done the next day after the mowing, or the ſecond day after, as the weather is more or leſs favourable, obſerving that, as the chief virtue of this hay reſides in the leaf and bloſſom, the leſs they are diſturbed the more valuable will be the fodder: on which account the tedding of this hay abroad, as is practiſed by ſome people, cannot fail to be of the greateſt injury. From the windrows, it ſhould be made up into graſs-cocks, which, having enjoyed the influence of the ſun and air for a day or two, may be thrown into large cocks for carting. But, if wet weather prevail during the ſeaſon for making this hay, it cauſes an infinite deal of trouble to the farmer; and the clover, from having been frequently ſhaken abroad, is deprived of its moſt nutritious particles, namely, the bloſſom and the leaf."

In the Survey of the County of Perth it is ſtated, that, "in making hay of clover and ryegraſs, ſome farmers adviſe to allow the hay to lie in the ſwath for two or three days; and after the ſuperfluous moiſture and dew are evaporated, in a dry day, either to ted it a little or turn the ſwaths, and in the afternoon to make it up into ſmall cocks, ſuitable to the ſtate of the hay. The only objection to this management is, that the hay on the ſurface of the ſwath is apt to be blanched by the weather, the juices exhaled by the ſun, and the flavour of the hay leſſened. This diſadvantage is, in a great meaſure, only imaginary; becauſe, after the hay has lain a day or two in the cocks, the whole becomes ſo much alike, that the expoſed part can ſcarcely, if at all, be diſtinguiſhed from that which was in the bottom of the ſwath. The dried part imbibes the juices of the moiſt, and the moiſt is kept open and more acceſſible to the air by means of the dry." But "the practice of others is, to cut down their hay in a dry day, and in the afternoon of the ſame day to make up their hay into ſmall cocks, by which means the whole juices are preſerved, and the damage of blanching completely obviated. The objections to this mode are, that it occaſions unneceſſary labour; that, if rain happens to fall, the cocks are ſo moiſt, that the hay may ſpoil before it can be opened out; and that they are ſo ſmall, if wind blows, that they are in danger of being overturned. As a remedy againſt its being too moiſt, it is recommended to draw two handfuls of hay to be laid acroſs on the top, by way of a thatching to the cocks; and, in the laſt caſe, to preſs them down a little with the hand, will render them more firm." However, "Mr. Patterſon, of Caſtle-huntley, in the Carſe of Gowrie, makes his hay by employing a perſon to follow the mowers, who turns the hay over and over till it be completely *winn*. If the ſeaſon be favourable, it is put into the tramp-rick in the ſtack-yard." This is a ſort of large cock frequently uſed in the northern diſtricts. And "upon his farm 300 ſtones, of 22lb. Engliſh to each ſtone, is accounted a good crop from an acre of land; which is not uncommon in that diſtrict, and in ſeveral other parts of the county. In the year 1786, he had 6000 ſtones of hay from a field of 13 acres, ſown originally among wheat; and for the ſecond crop of the ſame field, that ſeaſon he received 2l. 13s. 4d. per acre." But it is added, that "one precaution in this ſort of hay-making is abſolutely neceſſary, never to make hay up into the firſt cock, when it is in the leaſt degree wet; otherwiſe it ſoon becomes mouldy, by ſitting ſo cloſe together, as to exclude the air." But that, "whether a farmer thinks proper to make up his hay into the firſt cocks in either of the two ways above-mentioned, or in any other, which he may prefer, when theſe cocks are to be turned, and two or three of them put into one, according to the condition of the hay, he ſhould not neglect to put the drieſt part of the old cocks next to the bottom of the new ones; and continue to do ſo every time the ricks are turned, until the hay be ready for the tramp-rick." Further, that "it is almoſt unneceſſary to adviſe a farmer of experience, that in making tramp-ricks, they ought to be ſecured, by one rope over the top, in the direction of that point from which the moſt violent winds are expected to blow at that ſeaſon, or by two tranſverſe ropes, which is the ſureſt way; and that the ropes ought to be ſo fixed at the ends, as to draw no rain into the hay. The tramp-ricks ſhould alſo be neatly raked down the ſides, and well drawn all round cloſe to the bottom, ſo that the rain may fall from the ſides into the earth; not leaving the hay in a flounce at the ſkirts, in a ſlovenly manner, which part of the hay is entirely ſpoilt, if it remain long in the field. If tramp-ricks are made where the hay grew, make them always on the crown of the ridge, that the water may run freely off in the furrows. But it is more adviſable to carry the hay to the place where the ſtack is to be made, than to make the tramp-ricks in the field, becauſe the ſecond

crop of that year, and the growth even of the next year, is injured on the ſpot, where theſe ricks ſtand; and beſides, all the hay will be at hand, in making the ſtack, to get it cleverly finiſhed, in caſe of a change of weather. When hay has ſtood in the tramp-rick ſo long, but no longer, than is neceſſary to keep it from heating, becauſe the ſurface is often injured by the weather, the ſtack is frequently made in an oblong form, which is vulgularly called a *ſow*." And it is ſtated, that "it is computed that a ſtack of rye-graſs hay, which is a year old, weighs, for every cubic yard, ten or eleven ſtones of Dutch weight, *viz.* 17½lb. Engliſh, to the ſtone; clover and rye-graſs ſomewhat leſs, and clean clover ſtill leſs." And "it has been generally underſtood, but not examined with ſufficient accuracy, that four-pence is as good a price for hay weighed from the tramp-rick in Auguſt or September, as ſix-pence at Candlemas or March, *i. e.* that hay does decreaſe one-third in weight during that time. An experiment of Mr. Robert Webſter, at Mains of Errol in Scotland, will, it is ſuppoſed, throw ſome light on this matter. He weighed two ſtacks of hay from the tramp-rick, in Auguſt 1793, each conſiſting of 400 ſtones of ſimilar hay from the ſame field, and at the ſame time. Wiſhing to aſcertain how much the weight would decreaſe, he re-weighed the one upon the 17th of February 1794, which produced 372 ſtones; and the other being re-weighed upon the 26th of May 1794, produced 336. The firſt having only decreaſed at the rate of 7 *per cent.* inſtead of 33 *per cent.* as is commonly ſuppoſed; and the decreaſe of the ſecond being 16 *per cent.*" And, "by a ſimilar experiment with the crop of 1795, he found the decreaſe of the weight of hay about 16 ſtones more in every 400 ſtones, than it had been in the crop of 1793; but ſays that the hay was cut more green in the laſt, than in the firſt inſtance; which muſt always effect the decreaſe of weight for ſeveral months after hay is put into the ſtack." See CLOVER, RYEGRASS, SAINTFOIN, &c.

It may be noticed, that rouen, or the ſecond crop of hay, whether of the natural or artificial graſſes, will require leſs time in making than thoſe that are firſt cut, as they are generally more ſlender, and contain leſs moiſture than the firſt crops. In getting this ſort of hay, care ſhould be taken that it be perfectly dry when carried, as, without attention in this reſpect, it will be extremely liable to grow mouldy and bad in the ſtack. In order to this, it muſt be frequently turned.

Hay-Firing.—It is noticed, that, from the great miſchief frequently accruing from ſtacking hay in a damp ſtate, and the injuries of this kind which perpetually happen, one ſhould ſuppoſe that the farmers would be on the watch, and attentive to make uſe of every precaution to guard againſt it; but the many ſtacks which are yearly fired in the neighbourhood of London, are a ſufficient proof of their want of care in this particular. To prevent the fatal effects from the firing of hay, it ought to be a primary caution that the fodder be thoroughly made; and that every lump of graſs be intimately broken and divided, and have an equal participation of the ſun and air; and that the operation be not hurried, either with a view to leſſen the expence in making, or from an apprehenſion that rain may fall before the buſineſs can be finiſhed; or from a preſumption that the hay will weigh heavier in the tufts, if the whole has been got together before it be fully made, that it may thereby have the better chance of ſweating in the ſtack. As to the firſt argument, namely ſaving ſome expence in the wages of the labourer, it is conceived ſo futile, as ſcarcely to deſerve a ſerious anſwer; ſince the extra charges on this occaſion can be but trifling, and are comparatively of no account, when ſet againſt the hazard of firing the ſtack; by which event, the owner may be involved in utter ruin. As to the ſecond, or the apprehenſion of rain, the reply is, that it will be far more eligible to let the crop be ſpoiled in the field, than to run any hazard of its firing in the ſtack. And to the laſt, it may be obſerved, that hay, from upland meadows more eſpecially, if put into a large ſtack, will be in little danger of loſing either colour or weight by not heating. As to the low meadow, or marſh-hay, it may be got together with great expedition, as will be ſhewn hereafter. In a wet ſeaſon, at which time hay is under the greateſt danger of firing in the ſtack, it ſeems the moſt eligible method to divide it into ſmall parcels, as twenty loads in a ſtack, there being leſs danger of firing theſe ſmall ſtacks, than when the hay is laid into thoſe of larger dimenſions.

In the buſineſs of putting the hay into ſtacks, the firſt thing is to ſelect a clear ſunny day for the purpoſe, and not to be ſparing of hands on the ſtack, who, though they may appear to ſtand over thick, will be all of them found of ſome utility, not only in keeping the ſtack well trodden in every part, but by ſhaking and toſſing the hay abroad; whereby every particle of it will be again divided, and thus by enjoying the benefit of the ſun, it in a manner undergoes a ſecond making. Theſe precautions of employing a number of hands on the ſtack, and making choice of a fine day for the buſineſs, will at all times be found highly beneficial; but more particularly after a wet ſeaſon, and which will, in ſome meaſure, contribute to revive the colour, and retrieve the ſmell of ſuch fodder as may have been waſhed by continual rains in the firſt part of the haying. And, therefore, a farmer, who attentively watches the mutations of the weather, will always find his account in waiting a few days, when there ſeems a probability of a favourable change, rather than to begin his ſtack in a hazy day, and under the auſpices of a cloudy atmoſphere ſurcharged with moiſture.

Theſe comprehend the moſt important methods that are practiſed in the making of hay in different parts of the country.

HAY-*rake*, a tool of the rake kind, of which there are different ſorts employed in the making of hay, ſuch as the ſmall, ſhort, well known wooden toothed rake, and the large horſe-rake with long tines, or teeth. This laſt ſort has lately been found extremely uſeful in producing great diſpatch. See RAKE.

HAY-*ſow*, a name applied to a particular ſort of hay-rick.

HAY-*ſweep*, the name of an implement conſtructed for the purpoſe of collecting and conveying hay to the ſtack, or other place, in an eaſy and expeditious manner, as ſoon as it has been put up into rows. It is, conſequently, of much uſe where hay is to be ſtacked in the field, in ſaving a great deal of time and labour, as by ſuch a mode the hay may be got together with much fewer horſes, than where waggons or carts are made uſe of for the purpoſe.

There are implements of this nature conſtructed in very different forms and methods; but the ſledge uſed in Yorkſhire, and the ſweep invented and recommended by Mr. Middleton, in his "Survey of the County of Middleſex," are, perhaps, the moſt valuable. The former is ſhewn at *fig.* 1. *Plate Hay*; in which *a* diſplays a view of the whole ſledge, as deſcribed in the "Report for the North Riding of Yorkſhire;" *b*, the frame-work forming the bottom, which is boarded on the upper ſide in the manner ſeen at *a*; *c*, one of the ends having the top rail riſing from it; *d*, *d*, are two pieces of iron fixed on the frame *b*, by means of nuts and

and ſcrews; on each ſide is a ring, to which the horſes are attached, one horſe proceeding on each ſide of the row of hay, until the ſweep has become fully loaded; when one of the horſes croſſing the row the load is drawn to the ſtack. Upon its reaching which the horſes are turned about, when the rings run to the other end of the irons; the ſweep being drawn back from under the load, and returned, in order to collect another load in the ſame way as before.

The machine deſigned by Mr. Middleton operates in a ſomewhat different manner, though much on the ſame principle. It is drawn by four horſes, in pairs, having a boy to drive and manage each pair. Here alſo, before the work can take place, it is neceſſary that the hay ſhould be formed into rows, or ridges, as is commonly done before the loading of the carts or waggons, in the uſual mode of carrying this ſort of cattle-fodder. After which, in the view of ſweeping the hay together with more facility, a man with a fork muſt turn the ends of the rows up to the diſtance of two or three yards, in ſuch a manner as to form a kind of heap; then walking on ten, twenty, or forty paces, and breaking the rows, by turning the hay forward into another ſimilar heap; ſtill going on and repeating the ſame operation quite to the ends of the rows, which may be executed nearly as faſt as he can walk. The boy, who has the management of the pair of horſes to which the unloaded machine is attached, muſt then draw it acroſs the end of a row, and the inſtant the centre of the machine is at the middle of the row, his horſes muſt be turned ſhort about, to within a yard or two of the hay, ſo as to be in a proper poſition to ſet off, the other boy inſtantly placing his horſes on the other ſide of the row, and hooking the chain of his ſplinter-bar to the machine, pulling the gate-like ſide of it round, in order that it may claſp the hay. Every thing being prepared, the horſes ſhould be driven in a ſlow manner for the firſt twenty or forty yards; they may then, where the buſineſs requires diſpatch, increaſe their pace, they being urged on to their faſteſt walk; and from that into a ſlow ſort of trot, until as much hay be collected as the horſes can draw; then unhooking one end, the horſes at the other muſt be let turn from the hay, and brink out the machine from behind it; afterwards returning on the trot to the end of the next row, to repeat the ſame proceſs, care being taken to keep the horſes on each ſide of the row of hay at equal diſtances from it, and oppoſite to each other. In caſes in which the machine is loaded, and the intention is to draw the load to a diſtant place, the horſes cannot be kept too cloſe to each other. This machine is ſo generally known, that it is unneceſſary to give any repreſentation of it here.

HAY-*tea*, a ſort of infuſion prepared by pouring boiling water upon hay, after it has been cut into ſmall particles, the whole in ſome inſtances being then blended with ſome kind of ground or bruiſed. It has been aſſerted in the original ſurvey of Lancaſhire, that from two to three quarts of this mixture, when given to a cow every day, has been found to improve the flavour of the butter, and to bring it to its natural yellow colour. It has likewiſe been found beneficial in rearing young calves, when blended and incorporated with the milk, and exhibited to them as their food, being highly nutritious in its qualities.

In ſome late trials made by Mr. Saunders, and publiſhed in his treatiſe on the ſubject, it has alſo been conſidered as of great importance in the ſtore feeding of hogs even without the ground-meals, being in theſe caſes given in the form of ſoup, thickened a little with other ſort of cheap materials. Its cheapneſs and convenience are certainly greatly in its favour for this purpoſe. See HOG and SWINE.

HAY, WILLIAM, in *Biography*, was born in 1695 at Glynbourne in Suſſex, and by the death of his father was left heir to a ſmall eſtate. He received his grammatical learning in the country, after which he went to Oxford, where he remained till he was twenty years of age, when he removed to the Temple for the ſtudy of the law, which, owing to ill health, he was unable to purſue as a profeſſion. In 1728 he publiſhed "An Eſſay on Civil Government." In 1730 he deſcribed his own neighbourhood, and the hiſtorical events connected with that part of the country, in a poem entitled "Mount Caburn." In a ſhort time after this he engaged in public life, and was elected member of parliament for the borough of Seaford, which place he continued to repreſent till his death. He was a zealous whig, and for his ſervices in the cauſe he was made a commiſſioner of the victualling office; and when he reſigned this, he was appointed keeper of the records in the Tower. He died in 1755 of an apoplectic fit, which was ſuppoſed to be occaſioned by grief for the loſs of his youngeſt ſon juſt as he had paſſed through Weſtminſter ſchool with the higheſt reputation. Beſides thoſe already noticed, he was author of many other works on various ſubjects, which were collected in two volumes quarto, in the year 1794, to which a biographical account of the author is prefixed. His moſt popular piece was "An Eſſay on Deformity," which is a very ingenious collection of thoughts upon the bodily misfortune under which he laboured, and which he treats in a ſtrain of chearful philoſophy, proving, in the moſt ſatisfactory manner, how patiently he endured the circumſtances annexed to his condition.

HAY, in *Geography*, a market-town and pariſh in Brecknockſhire, Wales, is ſeated on the ſouthern bank of the river Wye; at the diſtance of 21 miles W. from Hereford. In the year 1800 the town conſiſted of 268 houſes, and 1170 inhabitants. Though conſidered a borough by preſcription, it has no privileges or civil immunities. The houſes, a few only excepted, are very indifferent, and are much ſcattered. The lord of the manor appoints a bailiff annually, to take the tolls of markets and fairs; and as his will or caprice was formerly the only law of the place, repeated inſtances of oppreſſive exactions have occurred. In the year 1576, Even ap David, a pedlar, by his will declared that his life was taken away by the cruelties of the bailiff, and requeſted his executors to proſecute the ſaid officer for murder. The attorney-general at length interfered; and at preſent the tolls are regularly and punctually paid to the lady of the manor, who holds an annual court-leet here. Leland deſcribes the town to conſiſt of "one poore paroche. In the ſuburb hard by Wy is a paroche church, meetely fair. There is alſo in the ſuburbe a chapel, where on Sunday I hard maſſe; not far from the paroche churche, in the ſuburb, is a great round hill of yerth, caſt up by mennes handes, other for a wynd-mille to ſtaad upon, or rather for ſum fortreſs of bataille. The town, within the wealles, is wonderfully decayed. The ruine is aſcribed to Oen Glindour. The walle hathe 111 gates and a poſterne. There is alſo a caſtel, the which ſum time hath been right ſtately." The church, now uſed by the inhabitants, is ſituated in a romantic ſpot cloſe to the river, and on an eminence, which is nearly precipitous on one ſide. Here are a weekly market and four annual fairs. Jones's "Hiſtory of the County of Brecknock," 2 vols. 4to. 1809, in which work is a plate of one of the ancient gateways.

HAY *Creek*, a river of Pennſylvania, which runs into the Schuykill. N. lat. 40° 16'. W. long. 76° 50'.

HAY's *Iſland*, a ſmall iſland in the Mergui Archipelago. N. lat. 9° 5'.

HAY,

HAY *Market*. Carts of hay which ſtand to be ſold in the hay-market, are to pay 3*d. per* load towards paving and repairing the ſtreet; and ſhall not ſtand loaded with hay after three o'clock in the afternoon, &c. on pain of forfeiting 5*s*. Hay ſold in London, &c. between the firſt of June and the laſt of Auguſt, being new hay, is to weigh ſixty pounds a truſs; and old hay, during the remainder of the year, fifty-ſix pounds, under the penalty of 2*s* 6*d*. for every truſs offered to ſale. 2 W. & M. cap. 6. 8 & 9 W. cap. 4. 31 Geo. II. cap. 40.

HAY *Worms*. Beſide the ſmall worms or animalcules bred in water, in which hay has been infuſed, which are only the objects of microſcopical obſervations, we find that it is a proper nidus of itſelf, ſometimes, for a much larger ſpecies of inſect called the hay-worm, whoſe origin and changes have not, as yet however, been properly obſerved. An animal which can be produced from the egg, and grow to its full ſize during the ſhort time that hay is left in the field in making, muſt be very quick in its growth; but yet it is found that multitudes of ſuch are produced, though probably few come to perfection, the removing of the hay naturally deſtroying many. In the Philoſophical Tranſactions we have an account of the ſame ſort of inſect breeding among cocks of barley while left in the field, many millions of them being diſcovered together, on ſtirring or lifting up the cocks with a cane. They are alſo found in the barns where barley is laid up, and are ſo numerous that they ſtrew the way the carts go that carry the barley home by the multitudes that are ſhook off. They are about half an inch long, as thick as a pigeon's feather, and of a whitiſh colour, ſhaded with faint ſtripes of a yellowiſh brown. They have fourteen feet, and ſeem evidently by all their marks to be true caterpillars. They are of an offenſive ſmell; and their excrements are hard white pellets of pure flower, like that of barley; whence it is plain that they eat the grain.

HAY, *Haya*, or *Haye*, a fence or incloſure, formed of rails; wherewith ſome foreſts, parks, &c. were anciently ſurrounded. See FENCE.

HAY is ſometimes alſo uſed for the park itſelf; and ſometimes for a hedge, or a place hedged round.

HAYS alſo denote a particular kind of nets, for the taking of rabbits, hares, &c.

HAYBOTE, HEDGBOTE, in our *Ancient Cuſtoms*, a mulct or recompence for hedge-breaking: or rather, a right to take wood neceſſary for making hedges, either by a tenant for life, or for years, though not expreſſed in the grant or leaſe.

It is mentioned in the Monaſt. tom. ii. p. 134. "Et concedo ei, ut de boſco meo heybot, &c." In the ſame place, huſbote ſignifies a right to take timber, to repair the houſe. See BOTE.

HAYCOCK, in *Geography*, a ſmall iſland in the Indian ſea, near the coaſt of Madagaſcar. S. lat. 13° 35'. E. long. 48 30'.—Alſo, a ſmall iſland in the Chineſe ſea. N. lat. 3° 27'. E. long. 107° 48'.

HAYCOCKS, a ſmall iſle in Delaware river, about 7 miles below Eaſton, in Northampton county, Pennſylvania.

HAYD, a town of Bohemia, in the circle of Pilſen; 24 miles W. of Pilſen.

HAYDEN, GEORGE, in *Biography*, organiſt of the church of St. Mary Magdalen, Bermondſey, acquired a reputation as a compoſer, without being previouſly noticed in the capital, a circumſtance which rarely happens.

In 1724 he publiſhed cantatas, one of which, ſung by Dat Platt, a popular ſinger at Sadler's Wells, called notice on the reſt, and they became in general favour with the lovers of pure and genuine Engliſh muſic, all over the kingdom. And, indeed, they ſeem the beſt which had been produced ſince Purcell's time. His two part ſong, "As I ſaw fair Chlora walk alone," and ſeveral ſingle ſongs by this obſcure muſician, enjoyed a laſting fame at clubs and feſtive meetings.

HAYDENHEIM, in *Geography*, a town of Wurtemberg, ſeated on the Brenz, famous for its pottery; 18 miles N.N.W. of Ulm.

HAYDN, JOSEPH, in *Biography*, maeſtro di capella to his ſerene highneſs, prince Eſterhazi, was born at Rhorau, in Lower Auſtria, in 1733. His father, a wheelwright by trade, played upon the harp without the leaſt knowledge of muſic, which, however, excited the attention of his ſon, and firſt gave birth to his paſſion for muſic. In his early childhood he uſed to ſing to his father's harp the ſimple tunes which he was able to play, and being ſent to a ſmall ſchool in the neighbourhood, he there began to learn muſic regularly: after which he was placed under Reuter, maeſtro di capella of the cathedral at Vienna: and, having a voice of great compaſs, was received into the choir, where he was well taught, not only to ſing, but to play on the harpſichord and violin. At the age of eighteen, on the breaking of his voice, he was diſmiſſed from the cathedral. After this, he ſupported himſelf during eight years as well as he could by his talents, and began to ſtudy more ſeriouſly than ever. He read the works of Mattheſon, Heinichen, and others, on the theory of muſic; and for the practice, ſtudied with particular attention, the pieces of Emanuel Bach, whom he made his model in writing for keyed inſtruments, as he candidly confeſſed to us when in England, in the ſame manner as Pope had formed himſelf upon Dryden.

At length he met with Porpora, who was at this time in Vienna, and, during five months, was ſo happy as to receive his counſel and inſtructions in ſinging and the compoſition of vocal muſic.

About this time he reſided in the houſe with the abate Metaſtaſio three years, as muſic maſter to mademoiſelle Martinetz, who owed to his inſtructions as well as to nature, thoſe talents which Haſſe, Jomelli, and all the great maſters of Metaſtaſio's acquaintance honoured with their approbation. During this time, Haydn had the great advantage of hearing the Italian language ſpoken with purity, and of receiving the imperial laureat's counſel, as to cloathing the fineſt lyric compoſitions with the moſt appropriate and expreſſive melodies. In 1759 he was received into the ſervice of count Marzin, as director of his muſic, whence, in 1761, he paſſed to the palace of prince Eſterhazi, to whoſe ſervice he was afterwards conſtantly attached.

All this information concerning Haydn's early life was procured before his arrival in England; but it is well known how much he contributed to our delight, to the advancement of his art, and to his own fame, by his numerous productions in this country; and how much his natural, unaſſuming and pleaſing character, excluſive of his productions, endeared him to his acquaintance and to the nation at large. It ought to be recorded, that twelve of his noble and matchleſs ſymphonies were compoſed here expreſsly for Salmon's concerts; and that it was from his ſpirit of enterpriſe and enthuſiaſtic admiration of Haydn, and love of his art, that we were indebted for his viſit to this country; beſides theſe ſublime ſymphonies, his piano forte ſonatas, his quartets and ſongs, were ſufficient to eſtabliſh his reputation as a great and original compoſer upon a laſting foundation, if only what he produced during the few years which he remained among us

was

was known. He arrived here in 1791, and returned to Germany in 1796.

The firſt time we meet with his name in the German catalogues of muſic, is in that of Breitkopf of Leipſic, 1763, to a "Divertimento à Cembalo, 3 Concerti à Cembalo, 6 Trios, 8 Quadros or quartets, and 6 ſymphonies in four and eight parts." The chief of his early muſic was for the chamber. He is ſaid at Vienna to have compoſed, before 1782, a hundred and twenty-four pieces for the bariton, for the uſe of his prince, who was partial to that inſtrument, and a great performer upon it. It is the ſame kind of viol di gamba as that upon which Lidl performed ſome years ago. See LIDL.

Beſides his numerous productions for inſtruments, he has compoſed many operas for the Eſterhazi theatre, and church muſic that has eſtabliſhed his reputation as a deep contrapuntiſt. His "Stabat Mater" has been performed and printed in England, but his oratorio of "Il Ritorno di Tobia," compoſed in 1775, for the benefit of the widows of muſicians, has been annually performed at Vienna ever ſince, and is as high in favour there, as Handel's "Meſſiah" in England. His inſtrumental "Paſſione," in ſixteen or eighteen parts, was among his later and moſt exquiſite productions, previous to his arrival in England. It entirely conſiſts of ſlow movements, on the ſubject of the laſt ſeven ſentences of our Saviour, as recorded in the Evangeliſts. Theſe ſtrains are ſo truly impaſſioned and full of heart-felt grief and dignified ſorrow, that though the movements are all ſlow, the ſubjects, treatment and effects are ſo new and ſo different, that a real lover of muſic will feel no laſſitude, or wiſh for lighter ſtrains to ſtimulate attention.

His innumerable ſymphonies, quartets, and other inſtrumental pieces, which are ſo original and ſo difficult, have the advantage of being rehearſed and performed at Eſterhazi under his own direction, by a band of his own forming, who have apartments in the palace, and practiſe from morning to night, in the ſame room, according to Fiſcher's account, like the ſtudents in the conſervatorios of Naples. Ideas ſo new and ſo varied were not at firſt ſo univerſally admired in Germany as at preſent. The critics in the northern parts of the empire were up in arms. And a friend at Hamburgh wrote us word in 1772, that, "the genius, fine ideas, and fancy of Haydn, Ditters, and Filtz, were praiſed, but their mixture of ſerious and comic was diſliked, particularly as there is more of the latter than the former in their works; and as for rules, they know but little of them." This was a cenſure which the admirable Haydn ſilenced long ago: for before his deceaſe he was as much reſpected all over Europe, by profeſſors, for his ſcience as invention. And the extent of his fame may be imagined, from his being made the hero of a poem on muſic, in Spaniſh, written and publiſhed at Madrid thirty years ago, entitled "La Muſica Poema, par D. Tomas de Yarte." (See SPANISH *Muſic*, article YRIARTE.) This ſublime work was produced for Cadiz. He has, not long ſince, publiſhed it in ſcore with German and Italian words, ſo that it may be performed as an oratorio.

The laſt of his compoſitions which were received in England ſubſequent to the "Creation," were two ſets of quartets, of which the firſt violin, calculated to diſplay Salamon's powers of execution and expreſſion, is very difficult, and his "Seaſons." See SONG.

But it may be laid down as an axiom in muſic, that "whatever is *eaſy* is *old*, and what the hand, eye, and ear are accuſtomed to; and, on the contrary, what is *new* is of courſe *difficult*, and not only ſcholars but profeſſors have it to learn." The firſt exclamation of an embarraſſed performer and a bewildered hearer is, that the muſic is very *odd*, or very *comical*; but the queerneſs and comicality ceaſe, when, by frequent repetition, the performer and hearer are at their eaſe. There is a general cheerfulneſs and good humour in Haydn's allegros, which exhilarate every hearer. But his adagios are often ſo ſublime in ideas and the harmony in which they are clad, that though played by inarticulate inſtruments, thay have a more pathetic effect on our feelings than the fineſt opera air united with the moſt exquiſite poetry. He has likewiſe movements and paſſages that are ſportive, playful, and even groteſque, for the ſake of variety; but they are often ſo ſtriking and pleaſant, that they have the effect of *bon mots* in ſpeaking or writing.

His grand and ſublime oratorio of the "Creation," and his picturеſque and deſcriptive "Seaſons," compoſed ſince his departure from England, if muſic were a language as intelligible and durable as the Greek, would live and be admired as long as the Iliad and Odyſſey of Homer. And we cannot help thinking that future ages will be as curious to know when and where he flouriſhed, as the country and chronology of Orpheus and Amphion.

HAYE, JOHN DE LA, was born at Paris in the year 1593, became a Franciſcan friar, and was appointed preacher in ordinary to queen Anne of Auſtria. He died at Paris in 1661. He publiſhed, in 1643, a collection of Commentaries on the Scriptures, in five volumes folio; and in 1660 another work of the ſame kind, in nineteen immenſe folios, entitled "Biblia maxima, cum Annotationibus diverſorum." On this compilation father Simon beſtows much praiſe. Another perſon of the ſame name, a Jeſuit, died in 1614, and was author of a "Harmony of the Evangeliſts," in two volumes folio, and other works. Moreri.

HAYE, *La*, in *Geography*, a town of France, in the department of the Indre and Loire, and chief place of a canton, in the diſtrict of Loches; 26 miles S. of Tours. The place contains 850, and the canton 5648 inhabitants, on a territory of 190 kiliometres, in 10 communes.

HAYE-*Dupuis*, *La*, a town of France, in the department of the Channel, and chief place of a canton, in the diſtrict of Coutances; 15 miles N. of it. The place contains 986, and the canton 14,403 inhabitants, on a territory of 205 kiliometres, in 25 communes.

HAYE-*Peſnal*, *La*, a town of France, in the department of the Channel, and chief place of a canton, in the diſtrict of Avranches; ſix miles N. of it. The place contains 957, and the canton 9356 inhabitants, on a territory of 127½ kiliometres, in 20 communes.

HAYE's *Iſland*, a ſmall iſland of New South Wales, formed by the rivers Nelſon and Hays.

HAYES, CHARLES, in *Biography*, a mathematician and chronologiſt, little known to the literary world, though he was author of many excellent works. He was born in the year 1678, and entered while he was young into the Royal African Company, ſpent ſome time on the continent of Africa, and from the knowledge which he obtained of their affairs, roſe to the chief management of them at home, and was for many years annually choſen deputy governor of the company. In 1704 he diſtinguiſhed himſelf by a "Treatiſe on Fluxions," the only work to which he put his name. In 1710 he publiſhed a ſmall pamphlet, entitled "A new and eaſy Method to find out the Longitude from obſerving the Altitudes of the Celeſtial Bodies;" and in 1723 "The Moon, a philoſophical Dialogue," intended to ſhew that the moon poſſeſſes a native light of her own. Mr. Hayes was a good linguiſt, as well in the Hebrew as in the Greek and Latin, was a great admirer of the Septuagint verſion of the Old Teſtament, and publiſhed, in 1736, "A Vindication of the Hiſtory of

of the Septuagint." His next piece, intended to aſcertain the true year of Chriſt's nativity, was "A Critical Examination of the Goſpels of Matthew and Luke," &c. In 1753, on the diſſolution of the Royal African Company, he retired to Down in Kent, when he undertook the vaſt labour of compiling a work under the title of "Chronographia Aſiatica et Ægyptiaca ab orbe condito ad Chriſtum natum per Annos 5500, ad fidem Scripturorum Vetuſtiſſimorum reſtituta et illuſtrata." This work he did not live to print, though it was finiſhed when he died in 1760: and in the preceding year he appriſed the world of the employment in which he had been engaged by publiſhing a ſpecimen of it.

HAYES, WILLIAM, Dr. in muſic, who began his career early in life, as organiſt of St. Mary's in Shrewſbury, being the firſt appointment to the office, after the erection of an inſtrument, in that church, by Harris and Byfield. We believe that he quitted Shrewſbury on the death of Goodſon, organiſt of Chriſt-church, Oxon, where he ſettled, and was ſucceſſively graduated, appointed profeſſor of muſic, organiſt of ſeveral colleges, and ſole director of the choral meetings, concerts, and encænia, and every muſical exhibition in that univerſity to the time of his death, about 1779.

Dr. William Hayes was a ſtudious and active profeſſor; a great collector of curious and old compoſitions, and poſſeſſed of conſiderable genius and abilities for producing new. He publiſhed, while at Shrewſbury, a collection of Engliſh ballads, his maiden compoſition. But at Oxford his eccleſiaſtical compoſitions for different colleges were innumerable; yet, being local, they were never printed, and but little known out of Oxford. Thoſe productions which gained him the moſt general celebrity were his canons, catches, and glees, for the Catch-club, in London, during the firſt years of its inſtitution; ſeveral of which were juſtly crowned. His canon of "Let's drink and let's ſing together," is perhaps the moſt pleaſant of all thoſe laboured compoſitions which go under the name of canons.

He was a very good organ-player, and at the inſtallation of lord North as chancellor of the univerſity of Oxford, played the organ in the theatre, in a full and maſterly manner.

He had a true ſenſe of Handel's ſuperior merit, over all contemporary compoſers; and on the publication of Mr. Aviſon's well-written "Eſſay on Muſical Expreſſion," in which it is perpetually inſinuated that Geminiani, Rameau, and Marcello, were greatly his ſuperiors, Dr. Hayes took fire, and produced a pamphlet, intitled "Remarks on the Eſſay of Muſical Expreſſion," written with much more knowledge of the ſubject than temper: he felt ſo indignant at Aviſon's treatment of Handel, that he not only points out the falſe reaſoning in his eſſay, but falſe compoſition in his own works.

HAYES, *Dr.* PHILLIP, ſon, and ſucceſſor to the preceding muſic profeſſor at Oxford, was regularly educated by his father, in the ſame art. When grown up, after he had loſt his treble voice, which dropped into a tolerable tenor, he was admitted one of the gentlemen of the king's chapel, and reſided chiefly in London, till the deceaſe of his worthy father; who having eſtabliſhed a family intereſt in the univerſity, ſucceeded to all his honours and appointments; but not talents, temper, or importance. With a very limited genius for compoſition, and unlimited vanity, envy and ſpleen, he was always on the fret; and, by his ſituation, had a power, which he never ſpared, to render all other muſicians uncomfortable. No one entered the univerſity occaſionally, or from curioſity, that did not alarm him. His extreme corpulency will be longer remembered than his abilities, of which he has left no example that we can recollect worthy to be recorded.

HAYES, *The*, in *Geography*, rocks near the N.E. coaſt of the iſland of Guernſey, between the ſmall iſlands of Harnit and Hummet.

HAYLING, ISLE OF, in the hundred of Boſmere and Portſdown diviſion of the county of Hants, England, includes about 5000 acres of land, is completely ſurrounded by the ſea, and divided into the pariſhes of North Hayling and South Hayling, in each of which is a ſmall church. The houſes, which are principally conſtructed of brick, were returned, in the year 1801, as 102, inhabited by 578 perſons. The chief branch of trade carried on in this iſland is the making of *ſalt*, which has been an article of manufacture here from time immemorial. One ſaltern is recorded in the Domeſday ſurvey, which paid ſix ſhillings and eight-pence: at preſent there are five. Two fiſheries are alſo mentioned in the ſame record, as being then exiſting here. A priory was founded on the iſland previous to the Norman conqueſt; to which Henry I. granted the manor of Hayling. After the diſſolution, the priory lands were regranted to Henry earl of Arundel, and now belong to his deſcendant, the duke of Norfolk. Warner's Collection for Hampſhire, 6 vols. 4to.

HAYM, NICOLA FRACESCO, in *Biography*, born at Rome, but deſcended from a German family. This ingenious and accompliſhed man merits a place in all biographical dictionaries, on various accounts. Firſt, as a practical muſician and compoſer; 2dly, as a poet; and 3dly, as a medaliſt and antiquarian, though his name is only to be found in Apoſtolo Zeno's annotations to the Bibliotheca Italiana. But as he reſided long in England, where he ended his days, we are able to ſupply biographical deficiencies concerning him.

He arrived in England, ſeemingly on ſpeculation, in 1705, and we hear of him firſt as a ſinging-maſter; the Daily Courant informing us, that on the opening of the queen's theatre in the Hay-market (built by ſir John Vanburgh, and before it was called an opera houſe) "there would be ſinging between the acts of Vanburgh's comedy of the "Confederacy," by Signora Maria, as lately taught by Nicola Haym. Soon after he is mentioned as the principal performer on the violoncello in Clayton's opera of "Arſinoe," which he aſſiſted in bringing on the ſtage in the Italian manner. He muſt have been a ſuperior performer on the violoncello to be aſſigned the principal part, on that inſtrument, which during this early attempt at a muſical drama in the Italian manner, was the chief and almoſt ſole accompaniment to cantatas and opera ſongs. In 1707, he compoſed ſeveral airs to Engliſh words, and an overture for Pyrrhus and Demetrius. After Handel's arrival, and the performance of Rinaldo, which diſgraced all attempts at Engliſh operas, and operas half Engliſh and half Italian; he aſſociated with Dieupart and Clayton in eſtabliſhing a concert at York buildings. In 1710 he wrote the operas of "Etearco" and "Coriolanus," before the arrival of Rolli as opera poet.

In 1712, he entered the opera band, as a performer on the violoncello; and was opera poet in the following dramas ſet by Handel: Flavius, Rodelinda, Tamerlano, Ptolemy, Siroe, Radamiſtus, Otho, Veſpaſian, Artaxerxes, and Julius Cæſar. He likewiſe wrote the drama of Aſtyanax, for Bononcini, the moſt celebrated of all the operas which he compoſed while he reſided in England.

During all theſe muſical and poetical occupations, he compoſed and publiſhed a work on medals, which is ſtill held in high eſtimation by the curious, entitled "Il Teſoro Britannico,"

tannico," containing the delineation and deſcription of all the Greek and Roman medals in every form and metal, which had not been previouſly publiſhed, 2 vols. 4to. 1719 and 1720, a work of immenſe labour and erudition. He likewiſe wrote two tragedies, "La Merope," and "La Demodice," and in the laſt years of his active life, he drew up and publiſhed propoſals for a hiſtory of muſic, upon an admirable plan; but it was not encouraged, which is much to be lamented, as far as Italy was concerned; as he was not only a good practical muſician, but a man of extenſive learning, and perfectly acquainted with the hiſtory of the art in his own country, and its progreſs in England during his reſidence there.

He had not only knowledge in counterpoint, but genius for compoſition, as he publiſhed at Amſterdam, in 1713, two ſets of ſonatas for two violins and a baſe, which are little inferior to the ſonatas of Corelli. There is more variety in them, though leſs grace.

He died in March 1730, and his effects were ſold by auction ſoon after his deceaſe. Apoſtola Zeno, a man of great learning and critical ſagacity, ſpeaks highly of the accuracy of Haym's, medallic-delineations in his "Teſoro Britannico," and in his poſthumous work, La Bibl. Ital. We have conſtantly found him (Haym) faithful in his account of books, particularly in his liſt of *Librarii*, as far as his own exiſtence reaches; but in the enlarged edition, publiſhed at Milan 1771, the liſt is extended to the time of Tartini, whoſe "Trattato di Muſica," publiſhed in 1754, is included.

HAYMAN, Francis, an hiſtorical painter, who was a native of Devonſhire, and pupil of Brown. He was principally employed in making deſigns for frontiſpieces, &c. to books, in which he rarely well ſucceeded. He is mentioned here, becauſe in the former part of his time he was the beſt this country could boaſt of, and was the painter of thoſe pictures relative to lord Clive's conqueſts in India, which are in the Rotunda at Vauxhall, and which are by far his very beſt performances. He was a rough mannered man, and a humouriſt, with good natural parts; a character often taſted by contemporaries, but which ſeldom aſſimulates with, or forgives the riſing generation. He uſed to delight in relating a circumſtance, which occurred to himſelf, of a whimſical nature. Paſſing along a ſtreet he obſerved a porter carrying a hare in a careleſs manner, dragging it on the ground, which a dog taking a fancy to, now and then made a ſnap at. At length the porter ſtopping to drink laid down the hare, and the dog taking advantage of that nearly tore it to pieces. Hayman, enjoying the joke, left his buſineſs neglected to watch its progreſs, and ſee to whom a hare ſo treated was directed. After loſing a conſiderable time he found the porter turn into the ſtreet where he himſelf lived, and rap at his own door, when he had the mortification to find that he had been enjoying, heedleſsly, his own misfortune. He had much ſucceſs in his practice, and lived to the age of 68, dying in 1776.

HAYN, in *Agriculture*, an old term employed to ſignify the operation of incloſing graſs lands with a hedge or ſome other means, in order to preſerve them from being paſtured with neat cattle or other ſorts of animals; conſequently, to *hayn up* implies the ſhutting up ſuch graſs grounds as are intended for being mown or fed off afterwards by live ſtock.

Hayn, or *Groſenhayn*, in *Geography*, a town in Saxony, in the margraviate of Meiſſen, containing three churches. This town is famous for having been the place in which the art of dyeing Saxon green and blue was firſt diſcovered; 16 miles N.N.W. of Dreſden. N. lat. 51° 18'. E. long. 13° 29'.

—Alſo, a town of Germany, in the county of Stolberg; 6 miles E. of Stolberg.

HAYNDORF, a town of Bohemia, in the circle of Boleſlau; 13 miles E. of Krottau.

HAYNEA, in *Botany*, ſo named by Willdenow, in honour of Frederick Theophilus Hayne, a German botaniſt, author of an elegant work entitled *Termini Botanici*, publiſhed by the former at Berlin, in quarto, with coloured plates. Willd. Sp. Pl. v. 3. 1787. (Pacourina; Aubl. Guian. 800. Juſſ. 174. Lamarck. Illuſtr. t. 665. Savigny in Lam. Dict. v. 4. 691.) Claſs and order, *Syngeneſia Polygamia-æqualis*. Nat. Ord. *Compoſitæ capitatæ*, Linn. *Cinarocephalæ*, Juſſ.

Gen. Ch. *Common Calyx* globoſe, imbricated; with numerous, elliptic-oblong, upright, acute, ſpinous ſcales. *Cor.* compound, tubular, uniform, florets all equal, perfect, fertile, monopetalous, funnel-ſhaped, with a regular, five-cleft, acute, ſpreading limb. *Stam.* Filaments five, capillary, the length of the tube; anthers acute, the length of the limb, united into a cylinder. *Piſt.* Germen obovate; ſtyle thread-ſhaped, the length of the ſtamens, very ſlender; ſtigmas two, acute, reflexed. *Per.* none, except the permanent calyx. *Seeds* ſolitary, obovate; down ſimple, ſeſſile, ſhort, ſpreading. *Recept.* fleſhy, chaffy; its ſcales roundiſh, concave, longer than the ſeeds, which they ſeparate from each other.

Eſſ. Ch. Receptacle fleſhy, chaffy. Down ſimple, ſhort. Calyx ovate, with imbricated, ſtraight, ſpinous ſcales.

1. H. *edulis*. (Pacourina edulis; Aubl. Guian. 800. t. 316.)—Found flowering in the month of June, on the banks of a river expoſed to the influx of the ſea, near Courou, in Guiana, by Aublet, from whoſe herbarium we have ſpecimens communicated by ſir Joſeph Banks. No other botaniſt, as far as we know, has ever gathered this plant. No account is given of the original generic name, which has the appearance of being French, and therefore in honour of ſome perſon; but Willdenow has thought proper to change it, and we follow his determination. The ſpecific name, *edulis*, is meant to expreſs that the receptacle is eatable, as well as the whole plant, according to Abulet, but he does not ſay whether recent or boiled. Its habit is that of a *Cnicus* or *Sonchus*. *Root* perennial. *Stems* ſeveral, ſomewhat branched, leafy, round, ſmooth, often zigzag, three feet high. *Leaves* alternate, large, ovate-oblong, greyiſh, ſmooth, veiny, fringed with little irregular, ſpinous teeth, their baſe running down into a winged footſtalk, which embraces the ſtem. *Flowers* ſolitary, oppoſite to each leaf, ſeſſile, ſcarcely an inch in diameter, blueiſh. The young foliage is ſlightly downy.—Juſſieu has erroneouſly placed this genus in a ſection whoſe calyx-ſcales are unarmed, probably from not having ſeen a ſpecimen. They are decidedly ſpinous, and the ſpines are yellowiſh, like thoſe on the leaves, ſo that it ought to be removed next to *Cnicus*, both in the natural and artificial ſyſtem, having indeed many characters in its habit like the alpine *Cnicus*, *ſpinoſiſſimus* and *oleraceus*.

HAYNES, Hopton, in *Biography*, was born in the year 1672, but nothing more ſeems to be known of him till about the year 1696, when he entered into the ſervice of his majeſty's mint; and by degrees he roſe, in 1723, to the office of the king's aſſay-maſter. In the year 1748 he reſigned the duties of his office; but, in conſideration of his long and faithful ſervices, his ſalary was continued him till he died in November 1749. He was the intimate friend of ſir Iſaac Newton, and was employed to tranſlate into the Latin language the two letters of that great man, on the true reading of the two texts, 1 John, v. 7. and 8, and 1 Tim. iii. 16. with a view, probably, to their circulation in foreign countries; but this object was not accompliſhed. At the

time of his death, Mr. Haynes had in the preſs a work entitled "The Scripture Account of the Attributes and Worſhip of God, and of the Character and Offices of Jeſus Chriſt;" which was the reſult of much inquiry into the meaning of the holy ſcriptures, without any guides, or the expoſitions of fallible commentators; and in ſpeaking of the ſubject, when he came to make known his own opinions, he ſays, "I think, I write, I ſpeak upon this important article, *viz.* that the God and Father of Jeſus Chriſt is the the only true God, with a clear underſtanding and a clear conſcience. I have no doubts, no ſcruples; no fear of offending God, or diſpleaſing Chriſt; no ſecret miſgivings that I am, or may be miſtaken; but a full and entire perſuaſion, that this foundation is moſt certain and infallible. I doubted early of the vulgar ſcheme [the Trinity]. To ſolve my doubts I read the holy ſcriptures, and them alone, for many years, with the greateſt attention and caution, with all earneſt deſire of finding the truth, without any bias, prejudice, or prepoſſeſſion." Speaking of the ancient fathers, and of the more modern reformers, Luther, Melancthon, &c. he ſays, "They can no longer impoſe on me with their authority: Chriſt is my maſter, and the holy ſcriptures my rule, and the only ſtandard of divine truth," &c. It is believed that ſome pains were taken to ſuppreſs this work after the author's death. It is almoſt certain that it was never publiſhed, in the ordinary acceptation of the word, till the year 1790, when an impreſſion of it was given to the world by the late Rev. Theophilus Lindſey. This was publiſhed in 8vo; and, in 1797, another edition in 12mo. with indices, and ſome account of the author in the preface, was printed at the expence of a ſociety "for promoting religious knowledge," &c. The work is now very rare; and notwithſtanding its excellence, and evident utility to biblical ſtudents, would ſcarcely repay a bookſeller the charges of a new impreſſion. See preface to "The Scripture Account," &c. "Sequel to Lindſey's Apology," p. 18, &c. Mr. Haynes left a ſon, named Samuel, in the church, who, on account of his ſervices as tutor to the earl of Saliſbury, was preſented by that nobleman to the rectory of Hatfield, in Hertfordſhire. He was author of "A Collection of State Papers, from the year 1542 to 1570, tranſcribed from Original Letters and other Memorials, never before publiſhed, left by William Cecil, lord Burleigh," &c. &c.

HAYNICHEN, in *Geography*, a town of Saxony, in the circle of Erzgeburg; 25 miles W. of Dreſden. N. lat. 50° 57'. E. long. 13° 3'.

HAYOBAYO, a town of Peru, in the dioceſe of La Paz; 25 miles W.S.W. of La Paz.

HAYWARD, or HAWARD, a keeper of the common herd of cattle of a town; who is to look that they neither break nor crop the hedges of incloſed grounds, and is ſworn in the lord's court for the due performance of his office. See AGILLARIUS.

HAYWARD, *Sir* JOHN, in *Biography*, a writer of Engliſh hiſtory, was probably educated for the profeſſion of the law, and took his degree of L.L.D. In 1599 he publiſhed "The firſt Part of the Life and Reign of king Henry IV." for which, on account of ſome things advanced in it, he was impriſoned by order of queen Elizabeth. She applied to Bacon to ſee if he could diſcover any paſſages that were treaſonable, but his reply was, that "for treaſon he found none, but for felony very many," which he explained by ſaying that the author had ſtolen many ſentences from Tacitus and tranſlated them into Engliſh. The queen, ſuſpecting that more perſons were employed in the work, would have extorted the ſecret by means of the rack, if ſhe had not been prevented by Bacon. In the reign of James I. he came into favour, and received the honour of knighthood. He now publiſhed the lives of the three Norman kings, and a tract "Of Supremacy in Affairs of Religion." He died in 1627, after which was publiſhed his "Life and Reign of king Edward VI." &c. The work for which, as a hiſtorian, he is moſt praiſed, is his "Life of Henry IV." Gen. Biog.

HAYWOODSBORO, in *Geography*, a poſt-town of Chatham county, in North Carolina; 305 miles from Waſhington.

HAZARD, a game on dice, without tables, is very properly ſo called, ſince it ſpeedily makes a man, or undoes him.

It is played with only two dice; and as many may play at it as can ſtand round the largeſt round table.

Two things are chiefly to be obſerved, *viz.* main and chance; the latter belonging to the caſter, and the former, or main, to the other gameſters. There can be no main thrown above nine nor under five; ſo that five, ſix, ſeven, eight, and nine, are the only mains flung at hazard. Chances and nicks are from four to ten: thus four is a chance to nine, five to eight, ſix to ſeven, ſeven to ſix, eight to five; and nine and ten a chance to five, ſix, ſeven, and eight: in ſhort, four, five, ſix, ſeven, eight, nine, and ten, are chances to any main, if any of theſe nick it not. Now nicks are either when the chance is the ſame with the main, as five and five, or the like; or ſix and twelve, ſeven and eleven, eight and twelve. Here obſerve, that twelve is out to nine, ſeven, and five; eleven is out to nine, eight, ſix, and five; and ames-ace and duce-ace, are out to all mains whatever.

But to illuſtrate this game by a few examples: ſuppoſe the main to be ſeven, and the caſter throws five, which is his chance; he then throws again, and if five turn up, he wins all the money ſet him; but if ſeven is thrown, he muſt pay as much money as there is on the board: again, if ſeven be the main, and the caſter throws eleven, or a nick, he ſweeps away all the money on the table; but if he throws a chance, as in the firſt caſe, he muſt throw again: laſtly, if ſeven be the main, and the caſter throws ames-ace, duce-ace, or twelve, he is out; but if he throws from four to ten, he hath a chance; though they are accounted the worſt chances on the dice, as ſeven is reputed the beſt and eaſieſt main to be flung. Four and five are bad throws (the former of which being called by the tribe of nickers, little dick-fiſher) as having only two chances, *viz.* trey-ace, and two duces, or trey-duce and quater-ace; whereas ſeven hath three chances, *viz.* cinque-duce, ſize-ace, and quater-trey. Nine and ten are in the like condition with four and five; having only two chances. Six and eight have indeed the ſame number of chances with ſeven, *viz.* three; but experienced gameſters nevertheleſs prefer the ſeven, on account of the difficulty to throw the doublets, two quaters, or two treys. It is alſo the opinion of moſt, that at the firſt throw the caſter hath the worſt of it. On the whole, hazard is certainly one of the moſt bewitching and ruinous games played on the dice. Happy, therefore, the man who either never heard of it, or who has reſolution enough to leave it off in time. See De Moivre's Doct. of Chances, p. 160, &c. See CHANCE and GAMING.

HAZARD, or *Richmond bay*, in *Geography*, a bay in Hudſon's bay, on the weſt coaſt of Labrador, with a great number of ſmall iſlands, called "Archiwinipick" by the Indians of the country. N. lat. 56° 35'. W. long. 75 50'.

HAZEL, HAZLE, or HAZLE-*nut*, in *Agriculture*, the name of a ſmall tree, of the nut kind, ſometimes made uſe of in the forming of hedges. It is not, however, well ſuited for this purpoſe, from the ſmoothneſs of its item. But it is extremely uſeful and proper in conſtructing hurdles, and other

other ſimilar ſorts of wattled work. See CORYLUS and FILBERT.

HAZEL-*mould*, a term applied to a yelloviſh kind of mould or ſoil, which has an extremely friable quality, being of the dry loamy deſcription. It is conſtantly met with where the ground is naturally of a good ſort. See SOIL.

HAZEL, *Witch*. See HAMAMELIS and ULMUS.

HAZELROUCH, in *Geography*, a town of France, in the department of the North, and the principal place of a diſtrict; 19 miles S. of Dunkirk. The place contains 6611, and the north and ſouth cantons 13,296 each, inhabitants, on a territory of 240 kiliometres, in 17 communes. N. lat. 50° 43′. E. long. 2° 37′.

HAZERYHUTTY, a town of Bengal, 15 miles S. W. of Nattore. N. lat. 24° 14′. E. long. 84° 44′.

HAZIR, a town of Curdiſtan, on a river of the ſame name, at its union with the Aras; 33 miles S. W. of Erbil.

HAZIRA, a town of Arabia, in the province of Hedsjas; 25 miles S. of Haura.

HAZLE. See HAZEL.

HAZLE, in *Mining*, is uſed in Cumberland and ſome other diſtricts, to expreſs grit-ſtone, free-ſtone, and what is called poſt, in ſome diſtricts.

HAZLE-*nuts*, *petrified*, in *Natural Hiſtory*, as alſo the trees, branches, juli or catkins, chivers or huſks, and leaves of the hazle, are very commonly found in peat moſſes, and in the alluvial accumulations in the bottoms of vallies, having but little fall, and on the flat ſhores of lakes and of the ocean, of which numerous inſtances are quoted in Parkinſon's "Organic Remains," vol. i. pages 61 to 68, and 94 to 97. In the alluvial flats, in the vallies in Derbyſhire, as at Matlock Bridge, the Buts' Paſtures in Aſhover, near Alport, &c., hazle-nuts, &c. are very common in layers, between the ſilt and gravel. Dr. Woodward, in his "Catalogue of Foſſils," vol. i. p. 21*, mentions nuts being found in Milncloſe mine, which doubtleſs fell or were waſhed into opens from the ſurface; and on the whole it ſeems clear, that all theſe belong to the claſs of peat foſſils, and are preſerved in the moſt modern of the earthy depoſits or accumulations; and that hazle wood, where truly aſcertained to be ſuch, muſt never be claſſed with the primitive ligneous foſſils found in the Bath free-ſtone, (Parkinſon's Organic Remains, vol. i. p. 68.) in the Woburn ſand, and in numerous other ſtrata in all parts of the world. Dr. Grew figures what he calls a hazle catkin, and deſcribes it, p. 267, of his "Rarities at Greſham College."

HAZLE-*hen*, in *Ornithology*, the name of a bird of the gallinaceous kind, common in the woods of Germany, and ſuppoſed by many to be the attagen of the ancients. See TETRAO *Bonaſia*.

HAZ-OGHU-BAZARZICH, or AGIOI-BASSORDSEIK, in *Geography*, a commercial town of European Turkey, in Bulgaria, inhabited by many rich Armenians; 38 miles S. of Driſtra.

HAZY ISLANDS, a cluſter of ſmall iſlands, in the North Pacific ocean. N. lat. 55° 55′. E. long. 225° 42′.

HEA, a maritime province of the kingdom of Morocco, bounded N. by the river Tanſif, E. by the province of Sherma, on Cherma, W. by the ocean, and S. by the province of Sus. The inhabitants of Hea are a trading people, but reſtleſs and little civilized; they are perpetually diſtracted by inteſtine broils. The province of Sherma, which lies between this and that of Morocco, has been diſmembered from that of Hea.

HEAD, *caput*, the uppermoſt or foremoſt part of the body of an animal.

Pliny, and other of the ancient naturaliſts, ſpeak of a nation of people without heads, called BLEMMYES.

We have accounts, in modern geographers and travellers, of people whoſe heads are as flat as the hand; it being the cuſtom among them to flatten the childrens' heads, when new-born, by paſſing them through a preſs, or laying them between two planks with a conſiderable weight thereon. Theſe are ſaid to be the inhabitants of the province of Coſaquas, on the river Amazons, in South America.

For an account of the various ſhapes of the head, and of the methods employed in producing them, among people of different nations, ſee CRANIUM.

HEAD, in *Anatomy*, that diviſion of the body, which is placed at the upper extremity of the vertebral column. We may conſider this in two different points of view: 1ſt. As a bony ſtructure, formed into cavities, which contain and protect the brain, the principal organs of ſenſe, and the inſtruments of maſtication; and, 2dly. As a more or leſs heavy maſs, articulated with the neck, and capable of being moved on it in various directions.

The upper two-thirds of the head form a large oval cavity, in which the brain is lodged, and towards the inferior and lateral parts of which the organs of hearing are placed; under the front of this is placed an aſſemblage of bones of an irregular figure, compoſing the face, and forming the orbits, the noſe, and the mouth, which contain the organs of ſeeing, ſmelling, and taſting, as well as thoſe of maſtication, and a part of ſuch as are concerned in ſwallowing.

The oſteology of theſe parts is conſidered under CRANIUM; together with the figure, dimenſions, and relative proportions of the component parts, the national differences in the form of the head, the ſtructure and formation of the teeth, &c. The contents of the cranium are deſcribed in the article BRAIN; the organ of hearing under EAR; the contents of the orbit and naſal cavities under EYE and NOSE; the organ of taſte under TONGUE; thoſe of maſtication and deglutition, excepting the jaws and teeth, which are deſcribed with the oſteology, under DEGLUTITION.

The external ſurface of the head preſents very different outlines in different parts of its circumference. On the upper part of its front aſpect, on the ſuperior portion, the ſides and back part, the forms are all convex or rounded, but do not exhibit the regular curves, and preciſe dimenſions, which are the attributes of geometrical figures. The aſpects, which we have now indicated, are all parts of the oval caſe, in which the brain is lodged. The integuments are covered, except on the forehead, by hair; and they are called altogether the hairy ſcalp. (See INTEGUMENTS.) In deſcending from the forehead we come to the face, of which the outline is very irregular, but ſo well known, that we ſhall be excuſed from particularly deſcribing it. The parts of this diviſion, which in common language are termed the features, are connected with the organs already alluded to; the eye-brow and eye-lids are deſcribed with the eye; the noſe with that organ; the lips and cheeks, the boundaries of the cavity, in which maſtication is carried on, under the article DEGLUTITION. The inferior ſurface of the head, which is its broadeſt and moſt extenſive aſpect, reſts upon the neck, and affords attachment to the muſcles, by which the former is moved upon the latter organ. The external view preſents to us the head, as extending, both in front and behind, beyond the out-line of the neck: the poſterior projection, which conſiſts of the convexity of the occiput, is the leaſt conſiderable; the anterior is compoſed of the front end of the lower jawbone called the chin. The

lateral convexities of the head are gently continued by a gradual ſlope into the ſides of the neck.

The head is articulated with the firſt vertebra of the neck, in ſuch a manner, that the canal of the ſpine correſponds to the foramen magnum of the occipital bone. And the ſituation of this articulation is nearly in the centre of the baſis cranii; nearly in the middle of a line, drawn between the moſt prominent points of the inciſor teeth and occiput. The place of the great occipital foramen, and of the condyles placed towards its front, is nearly parallel to the horizon; coincides nearly with that of the palate; while that of the eyes and mouth is nearly vertical. Hence, in the erect attitude of the body, the former organs are directed forwards.

In conſequence of the articulation between the head and the vertebral column being placed nearly in the centre of the baſis of the ſkull, ſo that the ſpine is placed perpendicularly under the head, the weight of the latter is ſuſtained almoſt entirely by the former. The head would be in a ſtate of perfect equilibrium on the ſpine, in the erect attitude of the body, if the parts in front of this point exactly counterbalanced thoſe which are behind it. But the centre of gravity of the whole head falls in front of the articulation; ſo that it would incline forwards on the atlas, if all extraneous ſupport were ſuddenly removed. This tendency of the parts is reſiſted partly by a ligament, which paſſes from the vertebra of the neck to the occiput, and partly by the muſcles, which are placed at the back of the articulations.

The ligamentum nuchæ, or cervical ligament, (ligament ſurépineux cervical of Bichat,) is a thin fibrous ſtratum, attached to the ſpines of the cervical vertebra on one ſide, and to the occiput on the other, and affording attachment to various muſcles at the back of the neck. It has two flat ſurfaces, which are turned towards the right and left cervical muſcles; an anterior, a ſuperior, and a poſterior margin. The former of theſe is affixed to the ſpinous proceſſes; the ſecond to the external perpendicular ridge, and to the tuberoſity of the occipital bone; and the third is extended in a ſtraight line from the occipital tuberoſity to the laſt cervical ſpine. The compoſition of the ligament is of a fibrous nature, and generally very thin: the poſterior margin in general is its thickeſt part. In ſome ſubjects it is very weak. Its uſe ſeems to be that of affording ſome ſupport to the head, and preventing it from inclining forwards. We ſhall be able to underſtand the anatomy and uſe of this ligament beſt by obſerving it in quadrupeds, where the ſituation of the occipital condyles, and the principles on which the head is maintained in its poſition, with reſpect to the vertebral column, are ſo different from what we obſerve in the human ſubject.

The former ſubject is conſidered in the article CRANIUM, under the head of *the compariſon of the human ſkull to that of animals*. In conſequence of the occipital condyles being placed ſo far back in the head, as we ſee them to be in animals, where, in moſt inſtances, they are at its poſterior ſurface, the whole maſs of the head, inſtead of being in equilibrio on a perpendicular column placed under it, is in front of that column; and requires for its ſupport a cervical ligament of enormous thickneſs and ſtrength, of which we can form no adequate notion from the inconſiderable analogous part in the human ſubject. If the ſpine were placed perpendicularly in a quadruped, and the head thrown into the attitude, in which it would be in equilibrio on the ſpine, the eyes would be turned backwards, and the mouth directly upwards.

For the form of the bones, which conſtitute the groundwork of this articulation, we muſt refer to the articles CRANIUM and SPINE. Thoſe articulations of the latter, which deviate from the general diſpoſition, and conſequently require ſeparate notice, are eſpecially concerned in the motions of the head: they are, that of the occiput with the atlas, of the ſame bone with the axis, and that of theſe two vertebræ with each other: for, although the latter have no connection with the occiput, it is entirely ſubſervient to the rotation of the head, which moves in this caſe with the atlas. Each of theſe three articulations muſt be particularly deſcribed.

Articulation of the occiput with the atlas (articulation occipito-altoïdienne). The condyles of the former bone are received in the ſuperior articular cavities of the latter; the reſpective ſurfaces being covered by cartilaginous ſtrata. They are both directed obliquely inwards and forwards, ſo that the two joints approach each on the front, and recede behind. An anterior and a poſterior ligament, and a ſynovial membrane at each condyle, ſerve to maintain the bones in their proper relations to each other, and to facilitate their motion.

The anterior ligament is compoſed of two faſciculi: a ſuperficial one, narrow, thick, and rounded, deſcending from the baſilary proceſs to the tubercle of the anterior arch of the atlas; a broader, thin, and flattenened one, attached to the occiput between the condyles, and to the atlas between its articular hollows. The firſt is made up of parallel fibres; the ſecond, of which the fibrous ſtructure is not ſo diſtinct, of threads which purſue various directions. The ligament formed by their juxtapoſition correſponds to the recti muſcles in front, and behind to the odontoid proceſs and its ligaments.

The poſterior ligament, broader than the former, conſiſts alſo of two portions, which are attached above to the poſterior ſemi-circle of the foramen magnum, and divide below. The poſterior is fixed to the arch of the atlas; and the anterior is loſt upon the dura mater, the fibrous compoſition of which it reſembles, while the other has a looſer texture. This ligament, taken altogether, is broad, and very diſtinctly marked; it correſponds in front to the dura mater, behind to the poſterior recti muſcles, and the ſuperior oblique; on the ſides to the vertebral arteries, and ſub-occipital nerves.

The ſynovial membrane covers the condyle, and a ſmall part of the bone in front, on one ſide, and, on the other, the correſponding hollows of the atlas. As it paſſes between theſe, it lines, in front, a fibrous faſciculus, behind, a conſiderable portion of cellular ſubſtance, on the inſide, the extremity of the tranſverſe ligament, which thereby acquires a ſmooth ſurface, and a part of the odontoid ligament; moreover, ſome ſmall portions of fat projecting towards the joints, and formerly conſidered as glands.

Connection of the occiput with the axis (articulation occipito-axoïdienne). There are not here, as in the preceding articulation, any contiguous ſurfaces covered with cartilage, and conſequently moving on each other; the two bones are held together merely by two ſtrong lateral or odontoid ligaments, and by a poſterior ligament.

The lateral, or odontoid ligaments, are two in number, attached to the apex and ſides of the odontoid proceſs, continued upwards and outwards in a diverging manner, and inſerted in the inner part of the anterior end of each condyle. Their fibres are parallel, and united by a very cloſe tiſſue, and they form two thick, rounded and ſhort faſciculi. They correſpond behind to the next ligament, above, and in front to cellular tiſſue, which ſurrounds the odontoid proceſs and favours its motions.

The poſterior ligament (apparatus colli ligamentoſus, or occipito-

occipito-axoïdien,) is a broad flattened faſciculus, thin at its middle, and thicker on the ſides. Above it is attached to the baſilary ſurface of the occiput, it deſcends over the odontoid proceſs, and has the following terminations below. In front it is attached to the upper edge of the tranſverſe ligament, the ſucceeding or middle fibres are inſerted into the body of the axis, and the poſterior are confounded with the poſterior ligament of the vertebræ, of which they may be ſaid to be the ſuperior origin. It will be obvious from this deſcription that its fibres are of unequal lengths; they are diſpoſed in a parallel manner, and are cloſely arranged. Behind it correſponds to the dura mater, to which it adheres above; the baſilary proceſs of the occiput, the odontoid proceſs, the tranſverſe ligament, and the poſterior ſurface of the axis are covered by it on the front connection of the atlas with the axis (articulation atloïdo-axoïdienne). Here there are two modes of attachment: the odontoid proceſs is confined in a peculiar manner, and the body, the plates, and the articular proceſſes of the two vertebræ are joined together.

The odontoid proceſs poſſeſſes, for its articulation, two convex ſurfaces, an anterior and a poſterior, both covered by a thin ſtratum of cartilage. The former correſponds to a cartilaginous ſurface on the back of the anterior arch of the atlas; the latter moves againſt the tranſverſe ligament. The joint poſſeſſes two ſynovial membranes and a tranſverſe ligament.

The tranſverſe ligament is a thick and flattened fibrous faſciculus, rather broader in the middle than at the extremities, which are inſerted in the internal ſides of the upper hollows of the atlas. The ligament is extended behind the odontoid proceſs, deſcribes in its courſe about the fourth of a circle, and thus forms, with the anterior arch of the atlas, a kind of ring, in which the odontoid turns, or which turns upon it. It is contiguous, behind, to the ligament laſt deſcribed, in front, to the odontoid proceſs and its ligaments. Its fibres are parallel and very cloſe. A ſmall faſciculus, detached from its lower edge, is fixed to the body of the axis, and holds the ligament in its proper ſituation. The upper edge is ſometimes ſurmounted by a ſmaller tranſverſe band, having the ſame direction as the larger one, and ſeparated from it by cellular tiſſue.

The anterior ſynovial membrane covers the ſmooth ſurface of the atlas in front, and the anterior one of the odontoid behind. Where it is continued between theſe it is looſe, and ſurrounded by much cellular tiſſue.

The poſterior ſynovial membrane covers the poſterior ſurface, and a little of the ſides of the odontoid proceſs, and the front of the tranſverſe ligament. It is ſurrounded by much cellular ſubſtance, and allows a free motion of the parts.

The general conection of the atlas with the axis is effected by the two articular ſurfaces of theſe vertebræ, which, when compared to the correſponding proceſſes of the ſucceeding bones, are diſtinguiſhed by their horizontal diſpoſition and very great breadth. They are covered by thin cartilages, furniſhed with ſynovial membranes, and tied together by an anterior and a poſterior ligament.

The fibres of the anterior ligament ariſe from the inferior edge of the front arch of the atlas, deſcend, and are inſerted into the baſis of the odontoid proceſs and into the body of the vertebra. The recti majores partly cover this ligament.

The poſterior ligament is thin and very looſe, to permit the rotatory motions of the atlas on the axis, it ariſes from the poſterior arch of the former, and is inſerted into the laminæ of the latter. Its texture, which is almoſt cellular, has no analogy to the yellowiſh ligaments, of which it fills the ſituation. It correſponds in front to the dura mater, behind to the inferior oblique muſcles, and much cellular ſubſtance.

The ſynovial membrane is remarkable for its great laxity, which permits a correſponding extent of motion. It covers the articular ſurface, and a little of the neighbouring bony part of the atlas, then deſcends upon the axis, and covers its ſurface. Its looſe portion, continued between theſe two parts, is ſurrounded by much cellular tiſſue, on the inſide by the interior ligaments of the vertebral canal, and externally by the vertebral artery. This ſynovial membrane is rather ſtronger than the preceding ones.

Motions of the Head.—Theſe are of two kinds: 1ſt, thoſe in which the head is carried directly forwards, backwards, or in any other direction; and 2dly, rotation, in which it moves on its own axis. Two ſeparate articulations are provided for theſe movements: the former are effected by the joints compoſed of the occipital condyles, and the ſuperior hollows of the atlas; the latter by the connection of the atlas with the axis.

The motions of the head upon the atlas, are thoſe of flexion (in which the head is carried towards the front of the trunk, or forwards), extenſion (where it is moved in the oppoſite direction), and inclination to either ſide. In all theſe, the cervical region of the vertebral column muſt be previouſly fixed to afford a point of ſupport. The head repreſents in all a lever of the firſt kind, in which the fulcrum is at the joint, and the power and reſiſtance vary according to the kind of motion. The lateral inclination is very limited. Beſides theſe, Bichat mentions circumduction, or the ſucceſſive performance of the different kinds of motion juſt enumerated; but adds that it is very obſcure.

The motions forwards and backwards, although the moſt extenſive belonging to this joint, are ſtill very limited; and amount merely to a ſlight nodding in either direction. However, the narrow limits of flexion, extenſion, and lateral inclination, are compenſated by the movements of the cervical vertebræ; which carry the head with them. Whenever the latter part is moved in any conſiderable degree, the effect is produced by a general motion of the cervical vertebræ. Flexion of the occipito-atloidal articulation is attended with a motion of the chin downwards and backwards, a diminution of the ſpace between the lower and the vertebral column, and a conſequent relaxation and folding of the ſkin on the front of the neck. On the contrary, when the cervical region of the ſpine is moved forwards, the relation between it and the jaw continues nearly the ſame, and the ſkin is, conſequently, not affected. Moreover, in the former caſe, the head turns on itſelf; in the latter, where the cervical vertebræ communicate their motion to the head, a much larger arc of a circle is deſcribed by the latter.

The ligaments, which tie the odontoid proceſs to the occiput, limit the motion of the head in the cavities of the atlas. Luxation cannot be produced in theſe motions; the articular ſurfaces are held together too firmly, the motions are too obſcure, and the odontoid ligaments reſiſt too effectually.

The muſcles, producing theſe motions, may be divided into two claſſes; *viz.* thoſe which affect the articulation between the occipital bone and the atlas only, and thoſe which are calculated to affect others as well as that articulation. Of the ſecond claſs ſome are attached to the lower jaw, and others to the bones of the cranium. The former are: 1, recti capitis interni minores; 2, recti capitis laterales; 3, recti capitis poſtici minores; 4, obliqui capitis ſuperiores.

ſuperiores. The latter form two claſſes, of which one conſiſts of muſcles attached to the lower jaw, or os hyoides, and includes; 1, latiſſimi colli; 2, biventres maxillæ; 3, mylohyoidei; 4, geniohyoidei; 5, geniohyogloſſi; 6, omohyoidei; 7, ſternohyoidei; 8, ſternothyroidei; 9, thyrohyoidei. The ſecond claſs contains muſcles attached to the bones of the cranium, and conſiſts of: 1, ſternomaſtoidei; 2, recti capitis interni majores; 3, certain fibres of the trapezii; 4, ſplenii capitis; 5, complexi; 6, recti capitis poſtici majores; 7, trachelo-maſtoidei. We obſerve, from this enumeration, that the motions of the head are provided for by very numerous muſcles. "In their general directions they are ſeen," ſays Dr. Barclay, "like all other muſcles, where motions in various directions are required, to differ conſiderably as to obliquity; and by their decuſſations at various angles, not only to ſtrengthen the connections of the bones, but to multiply the natural diagonals of their fibres. By this arrangement they combine their forces in ſuch an infinite number of ways, and with ſuch facility, that the parts, which they move, are all moved, directed, and moderated, with but little change in the relative poſition of their muſcular fibres, and yet, at the ſame time, with a rapidity, minuteneſs, ſteadineſs, and accuracy, that exceed comprehenſion." On the muſcular Motions of the Body, p. 319.

The greateſt number, and by far the moſt powerful muſcles, are placed at the back of the head, and paſs between the poſterior ſurface of the vertebral column and the occiput. Their action, in the erect ſtate of the body, counteracts the tendency, which the head has to fall forwards, derived from what we have already explained concerning the poſition of the occipito-atloidal articulation. Place the occipital condyles on any point of ſupport, and the head will incline forwards, unleſs it be held in equilibrio by a force applied behind; the extenſor muſcles, in the living body, have that power, and their conſtant exertion is neceſſary to the maintaining the head in equilibrio on the vertebral column. Hence, if their conſtruction be ſuddenly ſuſpended, as when a perſon falls aſleep in the ſitting poſition, with his head unſupported, that part does immediately incline forwards on the ſpine.

Motions of the atloido-axoidal articulation.—The head accompanies the firſt vertebra in all the motions of that bone upon the ſecond. Theſe are performed in a horizontal plane, and conſiſt of rotation to the right and left. The tranſverſe ligament behind, and the anterior arch of the atlas in front, manifeſtly oppoſe the ſmalleſt attempts at flexion and extenſion, becauſe they meet immediately in the odontoid proceſs with an inſurmountable obſtacle. Lateral inclination is equally prevented by the odontoid ligaments, which alſo ſerve to limit the rotations of the atlas on the axis. The looſeneſs of the ſynovial membrane admits the greateſt latitude of motion in the inferior horizontal planes of the atlas on the ſuperior ones of the axis; and this kind of rotation is limited merely by the odontoid ligaments. Beſides the breadth of the horizontal planes, and the laxity of the ſynovial membrane, which ſo greatly favour extenſive motion in this articulation; we obſerve, as a further diſpoſition calculated to ſecure the ſame object, that there are no lateral riſings that can in any way check the rotatory motion. The ſtate of the articulation, in this motion, is as follows: the arch of the atlas, and the tranſverſe ligament roll againſt the odontoid proceſs; the inferior horizontal planes of the former move over thoſe of the latter, and paſs conſiderably over their edges, in oppoſite directions on the right and left ſides. The ſynovial membranes, the anterior and poſterior ligaments, and the odontoid ligaments are ſtretched.

Probably luxation may occur, when this motion is carried beyond a certain extent with conſiderable force.

In the rotatory motions, the head and atlas are firmly held together by the muſcles, which paſs between thoſe parts; in this way they are fixed and prevented from obeying any forces that might incline them in any direction. The muſcles, which rotate, are the following: viz. 1, latiſſimi colli; 2, obliqui capitis inferiores; 3, a part of the ſplenii colli, and all the muſcles enumerated laſt, except the interni capitis majores.

"During theſe motions," ſays Dr. Barclay, "the muſcles peculiar to the head and atlas, and the muſcles of the neck, from the vertebra dentata downwards, become fixors; and thus the inclinations of the head and neck, ariſing from the action of the rotatory muſcles being every where prevented, the only directions, in which they can ſenſibly exert their forces, muſt be horizontal; in which directions, if they act alternately, the head muſt move, without inclination, towards the right or left, on the vertebra dentata. But, as in theſe motions the two halves of the ſecond pair cannot co-operate, the muſcles employed to roll the head, ſo as to turn the face to the right, are: 1, the right latiſſimus colli; 2, left ſternomaſtoideus; 3, part of the left trapezius; 4, 5, right ſplenius capitis and colli; 6, left complexus; 7, right rectus capitis poſticus major; 8, right obliquus capitis inferior; 9, right trachelo-maſtoideus. The remaining halves of the ſame pairs will roll it to the left; and the two halves of the ſame pairs act alternately as moderators and motors." On the muſcular Motions, p. 321.

HEAD, *water in the*, and *dropſy in the*. See HYDROCEPHALUS and DROPSY.

HEAD, *Injuries of*. See INJURIES *of the Head*.

HEAD, *Ulcers of the*. See PORRIGO.

HEAD *of Birds*. See BIRDS.

HEAD *of Fiſh*. See FISH.

HEAD is alſo applied in a general ſenſe, by analogy, to the uppermoſt or principal extremity of any thing; or figuratively, when ſpeaking of communities, to the ſuperior; and, when referred to place or priority, is that ſtation or poſition which is moſt honourable.

HEAD, in *Architecture*. Heads are uſed as an ornament of ſculpture or carved work, frequently ſerving as the key of an arch or plat-band, and other occaſions.

Theſe heads uſually repreſent ſome of the heathen divinities, virtues, ſeaſons, ages, &c. with their attributes. The heads of beaſts are alſo uſed in places ſuitable thereto: as a bullock's or ſheep's head, for a ſhambles or a market-houſe; a dog's for a kennel; a deer's or a boar's, for a park or foreſt; or a horſe's, for a ſtable, &c.

In the metopes of the friezes, and other parts of certain antique Doric temples, we meet with repreſentations of bullocks' or rams' heads flayed, as a ſymbol of the ſacrifices offered there.

In *Heraldry*, the heads of men, beaſts, birds, &c. are borne in armoury, either full-faced and in front, or ſide-faced and in profile, which muſt be diſtinguiſhed in blazoning.

Among *Medalliſts*, the different heads on ancient coins are diſtinguiſhed by the different dreſſes thereof. See MEDAL.

In the imperial medals, where the head is quite bare, it is uſually a ſign the perſon was not an emperor, but one of the children of one, or the preſumptive heir of the empire. Though we have inſtances of thoſe who were only Cæſars, and never reigned, being crowned with laurel or adorned

adorned with a diadem; as, on the contrary, we have ſome emperors heads entirely bare. The heads which are covered, are either covered with a diadem or a crown, or a ſimple caſk, or a veil, or with ſome other foreign covering; whereof the diadem is the moſt ancient. The ſenate firſt granted it to Julius Cæſar to wear the laurel crown, which his ſucceſſors took after him. The heads of deities are frequently diſtinguiſhed by ſome ſpecial ſymbol thereof.

HEAD is alſo uſed for the horns of a deer, as a hart, buck, &c.

Harts mew, or caſt their heads, every year, and get new ones.

The old hart or buck caſts his head ſooner than the young; and the time is about the month of February or March. Having caſt their heads, they inſtantly withdraw into the thickets, hiding themſelves in convenient places near good water, &c. and far from the annoyance of flies.

After they have mewed, they begin to *button* again in March, or April, *i. e.* to ſhoot out new horns, which at firſt appear like little branches.

Note, if a hart be gelt before he have a head, he will never bear any; and if he be gelt when he has a head, he will never after mew or caſt it. If only one of his teſticles be taken out, it is ſaid, he will want a horn on that ſide; and that, if one of the teſticles be only tied up, he will want the horn of the oppoſite ſide.

The age of a hart or deer is uſually reckoned by the number of heads. A deer of the firſt head, of the ſecond head, &c.

At one year they have nothing but bunches, called *ſignificators*, of horns to come. The ſecond year they appear more perfectly, but ſtraight and ſimple; this makes the firſt head, properly called *broches*, and in a fallow deer *pricks*. The third year they grow into two *ſpears*, or four, ſix, or eight ſmall branches. At the fourth, they bear eight or ten. At the fifth, ten or twelve. At the ſixth, fourteen or ſixteen. At the ſeventh year they bear their heads beamed, branched, and ſummed, as much as they will bear, never multiplying farther, but only growing in magnitude.

The names and diverſities of heads, in the hunting language, are as follow:

The part that bears the antlers, royals, and tops, is called the *beam*, and the little ſtreaks therein are *glitters*: that which is about the cruſt of the beam is termed *pearls*; and that which is about the bur itſelf, formed like little pearls, is called *pearls bigger than the reſt*; the *bur* is next the head, and that which is about the bur is called *pearls*; the firſt branch is called *antler*, the ſecond *ſur-antler*; all the reſt which grow afterwards, till you come to the crown, palm, or croche, are called *royals*, or *ſur-royals*; the little buds or broches, about the tops, are called *croches*.

The heads alſo go by ſeveral names. The firſt head is called a *crown top*, becauſe the croches are ranged in form of a crown; the ſecond is called a *palmed top*, becauſe the croches are formed like a man's hand. In all heads which bear not above three or four, the croches, being placed aloft, all of one height, in form of a cluſter of nuts, are called *heads of ſo many croches*. All heads which bear two on the top, and have their croches doubling, are called *forked heads*. All heads which have double burrs, or the antlers, royals, and croches, turned downwards contrary to the other heads, are called *ſimple heads*. See HUNTING.

HEAD is ſometimes alſo uſed for the whole man.

In this ſenſe we ſay, to offer a reward for a man's head.

In proſcriptions, there is a price ſet on a man's head.

Capitation denotes a tax laid upon each head, called alſo *poll* and *head-money*.

HEAD, in the *Military Art*. *Head of the camp* is the front or foremoſt part of the ground an army is encamped on, or that which advances moſt towards the field or enemy. The head of the camp is always to be the beſt fortified.

In the like ſenſe we ſay, the *head of the trenches*, the *head of the ſap*, *of the works*, *&c.* meaning the *fronts*, or *thoſe* parts next the enemy, and fartheſt from the body of the place. See TRENCH and ATTACK.

The *head of a horn-work* is that part contained between the flanked angles of the two demi-baſtions.

HEAD alſo denotes an ornamental figure erected on the continuation of a ſhip's ſtem, as being expreſſive of her name, and emblematic of war, navigation, commerce, &c.

HEAD-*ledges* are the thwartſhip pieces which frame the openings in the decks.

HEAD, in the *Manege*. The perfections required to the head of a horſe are, that it be ſmall, narrow, lean, and dry. Horſes with a big groſs head are apt, by their weight, to reſt and loll upon the bridle, and ſo to incommode the rider's hand. A horſe with a large head can never look ſtately, unleſs he have a long and very well-turned neck, and place his head well. Horſes with groſs, fat heads, much charged with fleſh, are too often ſubject to infirmities of the eyes.

But the chief things in a horſe's head is a good *onſet*, ſo as he may be able to bring his head into its natural ſituation; which is, that all the fore-part, from the brow to the noſe, be perpendicular to the ground; ſo that if a plummet were applied thereto, it would but juſt raze or ſhave it. See HORSE.

The head of a horſe is alſo uſed to import the action of his neck, and the effect of the bridle and wriſt.

To give a horſe the head, ſee ECHAPPER.

HEAD *in, and likewiſe the hips*, is a phraſe importing that you muſt paſſage your horſe with his *head and croupe in*, *i. e.* work him ſide-ways upon two parallel lines, of a ſtep or trot, ſo that when the horſe make the ſtep or volt, his ſhoulders make a *piſte* or tread, at the ſame time that his haunches give the tract of another; and the horſe plying or bending his neck, turns his head a little within the volt, and ſo looks upon the ground he is to go over.

HEAD, *Moors*, is underſtood of a horſe with a black head and feet, the body being uſually of a roan colour. It is alſo uſed by engineers for a kind of boom or grenade ſhot out of a cannon; in *Heraldry*, for a repreſentation, uſually in profile, of a *blackmoor's head*, ſwathed or rolled about with a bandage; frequently borne as a creſt; in *Chemiſtry*, as a cover or capital of an alembic, having a long neck, to convey the vapours raiſed by the fire into a veſſel, which ſerves as a refrigeratory. In *Muſic*, the head of a lute, theorbo, or the like, is the place where the pins or pegs are ſcrewed, to ſtretch or ſlacken the ſtrings.

HEAD, *Dragon's*, in *Aſtronomy*, &c. is the aſcending node of the moon or other planet.

HEAD-*ache*, in *Medicine*. See CEPHALALGIA and HEMICRANIA.

HEAD, in *Rural Economy*, that part of an animal by which the food is taken into the ſtomach, and which in all domeſtic quadrupeds ſhould be ſmall in proportion, well formed, and well connected with the neck and ſhoulders. See BREEDING and LIVE *Stock*.

HEAD, a term not unfrequently made uſe of by graziers to ſignify the firſt bite of graſs, eſpecially when fattening bullocks are concerned, in which caſe they are ſaid to *go a*

head

head in oppoſition to the *followers*, or thoſe which come after them.

HEAD, *Ill*, a diſeaſe in ſheep, of the jaundice kind. See YELLOWS.

HEAD *Keep*, a term which is frequently employed by graziers to denote the firſt *bite* of paſture lands, or the beſt *keep* that is afforded by the farm for the ſupport of cattle ſtock, ſheep, &c.

HEAD-*land*, a name moſtly made uſe of to ſignify the land or ridge which runs croſſways at the top and bottom of a field, and which ſerves for the purpoſe of turning the plough upon, in its cultivation. As much mould or ſoil is conſtantly accumulating upon them, in conſequence of the plough ſo frequently turning upon them, they become proper in ſome caſes to be formed into compoſts with lime or manures of ſome other kind. The work may in ſome inſtances be executed by means of the plough, but ſeldom in ſo complete a manner as by the uſe of the ſpade. In the former mode there is, however, a great ſaving of expence as well as time. The moſt proper manner of forming the ſuperficial materials of head-lands into compoſts, where plough-labour is wholly employed, is that of frequently ploughing over ſuch lands during the ſummer months, in order to break down and clean them well from all ſorts of weeds, and likewiſe to incorporate the lime or other matters very intimately with the particles of the mould; in which intention the lime, dung, or other manure ſhould previouſly be ſpread out in a thin even manner over every part, beginning the work of ploughing in the middle of the head-land. As ſoon as the calcareous ſubſtances have been well intermixed with the earthy materials, dung may be ſpread out, and be well blended with the other matters.

But where the ſoil of head-lands of this kind is of the more ſtiff clayey deſcription, it will be neceſſary to lay the earth up in high ridges for the winter ſeaſon, in order that it may be well broken down and mellowed by the froſt, harrowing it well in the ſpring with a heavy harrow, and afterwards incorporating the lime, dung, &c. in the manner that has been already adviſed.

In caſes where lime is the only ſubſtance made uſe of, the intermixture may be very completely formed by the plough and the harrow, care being taken not to apply the whole of the lime on at once, but at different times, ploughing and harrowing the land over well after each application of the lime. Even where dung is employed in this mode, it may be blended with the ſoil in the ſame method, as ſoon as the lime has become perfectly effete in the ſoil.

In theſe ways very good earthy compoſts may be formed with but little trouble or expence. See COMPOST and MANURE.

HEAD-*ſtock*, a term frequently applied to the beſt or leading ſtock by graziers.

HEAD is applied to the bank or principal ground of a reſervoir; alſo to the top water line of a mill or dam, or other variable pen of water.

HEAD *of Ayr*, in *Geography*, a cape on the W. coaſt of Scotland, in the county of Ayr. N. lat. 55° 30'. W. long. 4° 38'.

HEAD *of Elk*, a town of Maryland, at the head of Cheſapeak bay.

HEAD *of May*, a cape of South Wales, in the county of Pembroke; ſix miles W.S.W. of Pembroke.

HEAD-*borow*, or HEAD-*borough*, ſignifies the perſon who is the chief of the frank-pledge, and had anciently the principal direction of thoſe within his own pledge.

He was alſo called *burrow-head*, *bur-ſhoulder*, now *boſholder*, *third-borow*, *tything-man*, *chief-pledge*, and *borow-elder*, according to the diverſity of ſpeech in divers places.

This office is now uſually called a *high-conſtable*.

The head-borow, was the chief of ten pledges; the other nine were called *hand-borows*, or *plegii manuales*, &c.

HEAD, *by the*, in *Sea Language*, denotes the ſtate of a ſhip which is laden deeper at the fore-end than the after-end.

HEAD-*farcin*. See FARCIN.

HEAD-*faſt*, in *Sea Language*, ſignifies a rope employed to faſten a ſhip to a wharf, chain, or buoy, or to ſome other veſſel along-ſide.

HEAD-*land*. See LAND.

HEAD-*lines*, in a *Ship*, thoſe ropes of all ſails which are next to the yards, and by which the ſails are made faſt to the yards.

HEAD-*moſt*, in *Sea Language*, denotes the ſituation of any ſhip or ſhips, which are the moſt advanced in a fleet or line of battle.

HEAD-*mould-ſhot*, a diſeaſe in children, wherein the ſutures of the ſkull, generally the coronal, *ride*; that is, have their edges ſhot over one another; and are ſo cloſe locked together, as to compreſs the internal parts, the meninges, or even the brain itſelf.

The diſeaſe uſually occaſions convulſions, and is ſuppoſed to admit of no cure from medicine, unleſs room could be given by manual operation or a divulſion of the ſutures.

The head-mould-ſhot is the diſorder oppoſite to the horſe-ſhoe-head.

HEAD-*pence*, an exaction of a certain ſum formerly collected by the ſheriff of Northumberland from the inhabitants of that county, without any account to be made to the king. This was aboliſhed by the ſtatute 23 Hen. VI. cap. 7. Blount.

HEADS, a term uſed by builders for that kind of tile which they uſed to lay at the eaves of a houſe, being the full breadth of a common tile, and but half a tile in length.

HEAD-*rope*, in a *Ship*, is that part of the bolt-rope which terminates any of the principal ſails on the upper edge, which is accordingly ſewed to it.

HEAD-*ſails* are thoſe which belong to the fore-maſt and bowſprit; for it is by theſe that the head of the ſhip is governed, and by which it is made to fall off and keep out of the wind; ſuch are the fore-ſail, fore-top-ſail, fore-top-gallant-ſail, jib, fore-ſtay-ſail, and the ſprit-ſail, with its top-ſail: and theſe in quarter-winds are the chief drawing-ſails.

HEAD-*ſea* is when a great wave or billow of the ſea comes right a-head of the ſhip as ſhe is in her courſe.

HEAD-*ſtall*, in the *Manege*. See CAVESON.

HEAD-*ſtall*, among *Ancient Muſicians*. See PHORBEA.

HEAD-*tin*, in *Metallurgy*, is a preparation of tin-ore toward the fitting it for working into metal. When the ore has been pounded and twice waſhed, that part of it which lies uppermoſt, or makes the ſurface of the maſs in the tub, is called the head-tin; this is ſeparated from the reſt, and after a little more waſhing, becomes fit for the blowing-houſe.

HEAD-*to-wind*, in *Sea Language*, denotes the ſituation of a ſhip or boat when her head is turned to windward.

HEAD-*way* ſignifies the motion of advancing at ſea, and is generally uſed when a ſhip firſt begins to advance, or, in calm weather, when it is doubtful whether ſhe be in a ſtate of reſt or motion.

HEADFORD, in *Geography*, a ſmall poſt-town in the county of Galway, and province of Connaught, Ireland; 103 miles N. by W. from Dublin.

HEADINGS, are ſmall ſoughs or tunnels driven under ground to collect and draw off the ſprings of water from any tunnel, deep-cutting, or other large work.

HEALFANG, Healsfang, or *Halsfang*, in our *Ancient Cuſtoms*, ſignifies *colliſtrigium*, or the puniſhment of the pillory.

The word is compounded of two Saxon words; *halp*, *neck*, and *pangen*, *to contain*: "Pæna ſcilicet qua alicui collum ſtringatur." The healfang, however, cannot ſignify a pillory in the charter of Canutus, De Foreſtis, cap. xiv. "Et pro culpa ſolvat regi duos ſolidos, quos Dani vocant halfehang."

Healfang is alſo taken for a pecuniary puniſhment or mulct to commute for ſtanding in the pillory; and is to be paid either to the king or to the chief lord.

"Qui falſum teſtimonium dedit, reddat regi, vel terræ domino healfang." Leg. Hen. I.

HEALING, in its general ſenſe, includes the whole proceſs of curing or removing a diſorder, and recovering health.

In this ſenſe, medicine is defined the art of healing.

In its more reſtrained ſenſe, as uſed in ſurgery, &c. healing denotes the uniting or conſolidating the lips of a wound or ulcer.

The medicines proper for this intention, are called *incarnatives*, *agglutinatives*, *vulneraries*, &c.

Dr. Beal has a diſcourſe of ſanative or healing ſprings and waters, in the Philoſophical Tranſactions, N° 20.

Healing, in *Architecture*, denotes the covering the roof of a building.

The healing is various; as of lead, tiles, ſlate, Horſham-ſtone, ſhingles, or reed and ſtraw.

HEALTH, may be defined that condition of the living body, in which all its functions are performed without impediment or pain.

The animal machine conſiſts of a bony frame, connected by muſcles and ligaments, and including a variety of organs, which are deſtined to perform certain offices or functions. Thoſe offices immediately neceſſary to its exiſtence, which have therefore been called *vital* functions, and which cannot be interrupted without danger to life, are the functions of the circulation of the blood, of breathing, and of the irritability connected with the influence of the nervous ſyſtem. Poſſeſſing theſe powers alone, however, the machine would ſoon periſh, for its ſolids would be worn down, and its fluids diſſipated by the inceſſant motion, or they would be ſpontaneouſly corrupted. But the intelligent conſtructor of the machine has endowed it with powers of repairing its loſſes, and of counteracting its tendency to deſtruction. Hence the *natural* functions, as they have been called, of digeſtion, ſecretion, and excretion or diſcharge, were ſuperadded; organs were formed for the reception and tranſmutation of food and drink, for its conveyance into the blood-veſſels, for its appoſition to the different decaying parts, and for the diſcharge of that which was ſuperfluous or noxious; and other fluids, ſerving ſome uſeful purpoſe in the economy, were deſtined to be formed, by organs of ſecretion, from the general maſs. Thus conſtituted, the vital machine would be devoid of connection with the external world, had not the *animal* functions, the ſenſes, the powers of volition, and of locomotion, and the mental faculties been ſuperadded, by which we are enabled to acquire a knowledge of the phyſical circumſtances of the world, and to modify them according to our neceſſities and pleaſures. We learn from experience, however, that a being, thus endowed, is ſtill liable to decay, and to diſſolve into his priſtine elements; but againſt this contingency alſo an ample proviſion is made, in the generative faculties or functions, the diviſion of the ſexes, and the inſtinctive appetites connected with them. See Function, and Life.

While each and all of theſe operations of the living ſyſtem are performed with regularity, freedom, and eaſe, the body is ſaid to be in *health*. This ſtate of health, however, is compatible with conſiderable variety in the ſtate of the functions, both corporeal and mental; whence we ſee the various temperaments and conſtitutions of individuals, which often deſcend from one generation to another; the various degrees of talent and diſpoſition; of ſtrength, magnitude, and ſymmetry in the corporeal ſtructure, and even varieties of the particular functions, ſuch as digeſtion, reſpiration, &c. Health therefore, and diſeaſe, as we have before remarked, (ſee Disease,) are to be conſidered in ſome degree as relative terms, regarding the individual, as compared with the generality of men, and alſo with himſelf at different times.

The moſt perfect health, however, is generally connected with a certain ſtructure of the corporeal organs, and is marked by certain ſigns and qualities of the ſyſtem. Thus the ſtrongeſt conſtitution, in which the functions are uſually carried on in the moſt healthy manner, is found in a well-formed and proportioned body, which is neither very tall nor very ſhort, neither lean nor loaded with fat; which is rather ſtout than ſlender, and is eſpecially endowed with an open full cheſt, and a breadth of ſhoulders. The bones, in ſuch a frame, are ſomewhat large, the muſcles fleſhy, well marked, firm, and ſtrong; the ſkin ſoft, never dry, but with a ſlight tendency to moiſture, and its colour, eſpecially in the face, ſteady and not variable, whether verging towards the fair or the brown, provided it neither approximate to paleneſs on the one hand, nor to yellowneſs on the other. The countenance is open and cheerful, with bright and quick eyes; and the teeth ſound and ſtrong. The ſtep is firm, the limbs giving a perfect ſupport to the body; the walk erect; all exerciſe is performed with eaſe and freedom, and even labour, although ſevere and long continued, does not exhauſt or derange the ſyſtem. All the organs of the external ſenſes are capable of performing their functions, being neither dull on the one hand, nor too acutely ſenſible on the other; the ſleep is calm and continued, not eaſily diſturbed, refreſhing to the frame, and devoid, if not of all dreams, at leaſt of thoſe that are frightful; a ſleep which lays to reſt all the cares of life in a calm and grateful oblivion, or at leaſt ſoothes the mind with the agreeable phantoms of the imagination.

Among the ſigns of health may be alſo enumerated, a calm and regular circulation of the blood, the pulſe of the arteries being ſtrong, full, ſoft, and equal, neither too frequent nor too ſlow, nor eaſily excited to unuſual quickneſs; a full, free, ſlow, and almoſt imperceptible reſpiration, which is not greatly accelerated by exerciſe; a ſtrong and ſonorous voice, of a grave tone in men, and not eaſily rendered hoarſe; the halitus from the lungs agreeable, or at leaſt deſtitute of fætor; the mouth moiſt, and the tongue without fur, but not too red; the appetite good, and not requiring the aid of condiments, and the thirſt moderate; the digeſtion of all aliment eaſy and good, without eructation, or any uneaſineſs in the ſtomach; the diſcharge from the bowels of natural form, odour, and conſiſtence, and occurring daily; and the urine eaſily retained during a proper length of time, and then paſſed with facility; and though various in quantity, colour, and tranſparency, (according to the quantity of food, drink, exerciſe, &c.) depoſiting a proper

proper ſediment on ſtanding, and the ſlower this depoſition is made the better; the perſpiration from the ſkin free and regular, but not amounting to ſweating, except when powerful cauſes concur to excite it; and the internal ſecretions equally free and regular, and neither too copious or too ſcanty. "Sani denique hominis eſt, venerem appetere, et ad eam valere, et ſobolem procreare."

There are ſome peculiarities in the ſigns of health in the female conſtitution, connected with the organs and functions belonging to the ſex. Among theſe ſigns are a free and regular diſcharge of the catamenia, without pain, neither too copiouſly, nor in too ſmall quantity;—a regular period of utero-geſtation, an eaſy parturition, at the proper period, and a copious ſecretion of milk, for the ſupport of the offspring.

Good health, moreover, in both ſexes, conſiſts not only in the proper performance of the functions, mental and corporeal, when no impediment is applied; but alſo, in a tenacity, as it were, of this regularity, and in an accommodation of the habit to many variations in the weather and ſeaſons, the diet, and mode of life; and thus, in bearing with impunity many cauſes of diſeaſe, which would altogether deſtroy the weaker or leſs healthy ſyſtem, or at leaſt endanger its falling into a ſevere diſeaſe. The health of the ſame individual, though it continue good, is not always the ſame; for many great changes occur in the animal economy during life; ſo that one man ſcarcely differs ſo much from others, of the ſame age with himſelf, as he differs from himſelf at different periods of his life, whether we conſider his form, the ſtrength of his body, or the qualities of his mind, or the internal ſtructure and functions depending upon them. Whence it happens, that the moſt perfect health, which firſt conducted the tender infantile frame to its vigour and perfection, and long ſuſtained the man in that condition, afterwards by degrees diminiſhes the ſtrength of the ſyſtem, and at length wears it out. (Gregory, Conſpect. Med. Theoret.)

"Naſcentes morimur, finiſque ab origine pendet."

The *preſervation of health*, then, muſt conſiſt in avoiding all injuries to the organs of the body, and all derangements of the functions, which they perform, as far as lies in our power, conſiſtently with the exertions and expoſures which the duties of humanity require: in other words, in avoiding the exciting cauſes of diſeaſe, which have already been pointed out. (See Disease.) In a conſtitution, formed like that above deſcribed, with all the qualities conducive to the healthy performance of its functions, ſuch precaution indeed may ſeem almoſt ſuperfluous: but ſuch conſtitutions are not the lot of the majority of mankind; the majority have ſome weak part, ſome hereditary or conſtitutional prediſpoſition to certain maladies, or ſome acquired tendency to particular diſorders, from their education, profeſſion, and mode of life. It is to theſe more eſpecially, that the preſervation of health becomes an object of care, and by whom the precepts of the moraliſt and of the phyſician are not to be ſcorned with impunity. For with theſe perſons ſome one function or other is readily diſturbed or impeded; and ſuch is the general connection or ſympathy between the functions and organs of the body, that the whole ſyſtem is thus readily diſordered.

There are two circumſtances in the habits of life, by which the regularity of the functions is eſpecially maintained; namely, temperance in the gratification of the appetites, particularly the appetite for food; and exerciſe. Moderation in the uſe of food, while it does not overload the ſtomach, nor diſturb the proceſs of digeſtion, nor irritate the alimentary canal to inordinate action, ſupplies a good and ſufficient nutriment to the body, without incumbering any of its organs with a load of fat: and moderation in drink, while it contributes to perfect digeſtion, does not exhauſt the excitability of the ſtomach, and the ſyſtem at large, by its ſtimulus, nor produce thoſe derangements of the liver and other viſcera, with which ſickneſs, gout, dropſy, apoplexy, madneſs, and numerous other maladies are connected. (See Diet and Drunkenness.) In a word, temperance is itſelf the act of avoiding the cauſes of half the diſeaſes to which the organs and functions of the human frame are liable. And exerciſe, again, as we have already fully explained, by exciting a free circulation in the moſt minute ramifications of the vaſcular ſyſtem, in every organ of the body, contributes to the more perfect performance of all their reſpective functions; or, in other words, directly conduces to the healthful condition of the whole frame. (See Exercise.) When, in addition to theſe precautions, the influence of cold is guarded againſt by proper clothing; the proper recruiting of the exhauſted powers is effected by regular ſleep; and all exceſſive play of the paſſions and emotions of the mind is avoided by ſhunning the cauſes of their excitement; when, in ſhort, every exceſſive ſtimulus which can exhauſt the vital powers, or prevent their recruital, is moderated or avoided, even the delicate frame may be ſupported, through a long and not unhealthful life, and that with fewer chances of ſuffering great and dangerous diſeaſe, than the robuſt individual, who is altogether negligent of ſuch precautions.

It were altogether ſuperfluous to attempt any minute detail of the circumſtances neceſſary to be attended to, with a view to the preſervation of health. Theſe differ ſo much according to the peculiarities of individual conſtitution, the various modes of life, the differences of climate, &c. that it muſt be left in a great meaſure to individual experience and obſervation to aſcertain the *juvantia* and *lædentia*, as the medical phraſe is; or, in other words, to acquire a knowledge of what is beneficial or injurious to the habit under every circumſtance. For, in reſpect to the preſervation of health, the individual "muſt miniſter to himſelf:" and there is much juſtice in the homely adage, "every man is either a fool or a phyſician at forty," when applied in this ſenſe; although, when conſidered as applying to the cure of diſeaſes, it is an obvious abſurdity. Nothing is more common, than to hear numerous inquiries made of medical men about the *wholeſome* or *unwholeſome* qualities of this or that ſpecies of food; inquiries which muſt be deemed frivolous and uſeleſs, and which can only be anſwered by the interrogatories which were commonly uſed on ſuch occaſions by an eminent phyſician. "Doctor, is this wholeſome?"—"Do you like it?" ſays the doctor. "Yes."—"*Does it agree with you?*"—"Yes."—"Why then it is wholeſome." But the truth is, there is no defect of information upon this ſubject; moſt perſons well know, for inſtance, what are the properties, in reſpect to their own conſtitution, of the ſubſtances uſed as food and drink; but they *will* not make uſe of that knowledge. It is not from ignorance, but from want of controul over the appetites, that men are in the conſtant habit of deranging the functions of the body. And as we have already ſtated, it is not ſo much from the pernicious *qualities* of the ſubſtances employed, as from exceſs in the *quantity* of all, that the health is injured, and the conſtitution deranged. (See Diet.) The ſame obſervation will apply to the neglect of the other ordinary exciting cauſes of diſeaſe; the certainty of ſome preſent gratification is not to be foregone from the mere probability of future ſuffering.

Of

Of the Public Health.

The preceding obſervations relate only to individual health; but there are many conſiderations of great importance relative to what may be termed the *public health*, or to the removal of thoſe cauſes of diſeaſe, which originate from the circumſtances of the ſocial ſtate, eſpecially where men are congregated in great numbers. To theſe cauſes many of the moſt extenſive and fatal ſpecies of peſtilence, as well as of the ordinary epidemic diſeaſes, which afflict mankind, are in ſome degree or other to be aſcribed. (See EPIDEMIC.) For although theſe have been chiefly obſerved to occur at certain ſeaſons, and are therefore partly the reſult of certain conditions of the weather; yet theſe conditions of the weather operate principally, it would ſeem, through the medium of the circumſtances which the ſocial ſtate produces.

The two moſt frequent exciting cauſes of thoſe diſeaſes, which ſpread among the public at large, are, 1. The effluvia ariſing from the bodies of perſons already labouring under febrile diſeaſe, termed *contagious* or *infectious* effluvia, and which may be condenſed, and adhere to various ſubſtances, ſuch as clothing, furniture, &c.; and 2. Thoſe which ariſe from moiſt ſwampy ground, or from artificial collections of animal and vegetable matters, in a putrid or decompoſing ſtate. To the former of theſe, malignant, putrid, and ſpotted fevers, as they have been called, commonly owe their origin, and the plague, yellow fever, &c. probably their extenſive propagation; and from the ſecond, intermittents, remittents, dyſenteries, and perhaps the plague and the yellow fever, have been generally derived.

The operation of theſe cauſes may be moſt obviouſly traced in camps. All the writers on army-diſeaſes, from ſir John Pringle downwards, have ſhewn, that when a camp is ſtationed in a ſwampy ſituation, or when it has remained for a length of time on ground not originally ſwampy, but rendered ſo by the accumulating filth of an army, ſuch as the urine and excrements, the remains of the victuals, the water uſed in cookery and in waſhing, &c. which is neceſſarily impregnated with animal and vegetable matter, a certain claſs of diſeaſes inevitably appear among the men, and become prevalent throughout the camp; eſpecially in the autumnal ſeaſon, when the ground has been heated by the ſummer ſun, and the dampneſs increaſed by the rains of autumn. The diſeaſes, which occur in ſuch ſituations, are remittent and intermittent fevers, malignant or typhous fevers, and dyſentery. Under ſuch circumſtances the ſickneſs of the Engliſh army, employed in the recent diſaſtrous expedition to Walcheren originated; and ſuch were the diſeaſes which inflicted ſo much ſuffering and mortality among the troops. Now, that the origin of theſe maladies is to be found in the miaſmata or morbific effluvia, which ariſe from the ground in the ſituations alluded to, experience has abundantly proved. For where a ſwamp is extremely unhealthy, an adjoining height, only a few hundred feet above it, is found perfectly healthy; the draining of a ſmall marſh, or even the removal of the camp a few hundred yards only from the foul ground, which it had previouſly occupied, has been ſufficient to ſtop the progreſs of thoſe diſeaſes (ſee Dr. John Hunter, on the Diſeaſes of the Army in Jamaica, App. 3d edit.); and their occurrence has been prevented, and the health of the troops preſerved, in favourable ſituations, by burying the excrements, and forming proper receptacles underground for the urine, the remnants of victuals, foul water, &c.

Now, a large town is but an extenſive camp, ſo conſtructed, as to be deſtitute of the means of changing its ſituation, and, therefore, liable to be infeſted with the ſame diſeaſes as are endemic in camps, unleſs peculiar care be taken in adopting the precautions juſt alluded to. Hence, in all the old towns of Europe, while the ſtreets were unpaved, or the pavement ill-conſtructed; while every ſort of filth was permitted to be thrown into the ſtreets, and to remain there; while vaults and common ſewers were ſeldom adopted, and the drains ran above ground; while the office of ſcavenger was imperfectly, or not at all executed; while the ſupply of water was deficient, and the narrowneſs of the ſtreets prevented a free circulation of the air; in all large towns, under ſuch circumſtances, ſevere and fatal epidemics raged almoſt annually. The general prevalence of theſe maladies was at the ſame time greatly promoted by the internal domeſtic economy of the houſes; which, from the cloſeneſs of the ſituations in which they were injudiciouſly placed, and from inattention to ventilation and to cleanlineſs, afforded the moſt favourable *nidus* for the propagation of infection. During the 14th, 15th, 16th, and 17th centuries, the principal towns of Europe were in the condition juſt deſcribed; and the hiſtory of thoſe ages is as full of the phyſical miſeries of the people, as of their political troubles. The plague and putrid malignant fevers, which differed, perhaps, only in degree, every where prevailed, and their headquarters were always obſerved to be the naſtieſt parts of dirty, crowded, and ill-conſtructed cities, and their firſt appearance among the loweſt of the people. But the connection of peſtilence with ſuch cauſes is ſtill more ſatisfactorily proved, when we reflect that, in proportion as the nations of Europe have become civilized, and the arts of peace have been cultivated, theſe malignant and peſtilential diſorders have gradually diſappeared. Some of the cities of Europe, indeed, which, from natural or political cauſes, have been backward in adopting the improvements of modern times, ſtill continue to exhibit a picture of former diſeaſes, as well as of former manners. In Turkey the plague frequently occurs; and late in the 18th century it has appeared at Moſcow, as well as in Hungary and Denmark, &c. See Heberden's Obſervations on the Increaſe and Decreaſe of different Diſeaſes, &c. 1801.

As theſe general obſervations may not be deemed ſufficiently concluſive, as to the cauſes which principally influence the *public health*, we ſhall take this opportunity of illuſtrating their operation in the hiſtory of the progreſſive improvement of the health of the inhabitants of London, which has gone on in a correſponding ratio to the progreſs of improvement in the condition of the city, and in the domeſtic economy of the people.

Of the Health of London.

Hiſtory affords us abundant evidence of the filthineſs of the metropolis, and of the exiſtence of thoſe ſources of miaſmata which prevail in camps, and which, by the putrefaction and evaporation occaſioned by the autumnal heats and rains, were the conſtant ſource of diſeaſes, not only before, but even ſubſequent to the great fire in 1666. In the 14th and following centuries, the ſtreets were filled with common lay-ſtalls of all manner of filth and garbage, which the people were in vain ordered to remove from their own doors; the ſewers were in a very neglected ſtate; the drains all ran above ground; in many ſtreets there was no pavement at all, and the acceſs of pure air was prevented by the projecting houſes, almoſt meeting at top, the intervening ſpace being filled with enormous figs: nor was the internal ſtructure and economy of the houſes more favourable to health. Eraſmus, in a letter to the phyſician of cardinal Wolſey, aſcribes the *ſweating ſickneſs*, and the plague, from which the Engliſh were hardly ever free, in a great meaſure to the in-

commodious form and bad expoſition of their houſes, to the filthineſs of the ſtreets, and to the ſluttiſhneſs within doors. "The floors," he ſays, "are commonly of clay, ſtrewed with ruſhes, which are occaſionally renewed, but underneath lies unmoleſted an ancient collection of beer, greaſe, fragments of fiſh, ſpittle, the excrements of dogs and cats, and every thing that is naſty." Even the floor of the preſence-chamber of queen Elizabeth in Greenwich palace, was, according to Hentzner, "ſtrewed with hay, after the Engliſh faſhion." See Heberden loc. cit. Northouck's and Maitland's Hiſtory of London.

We are enabled to form ſome judgment of the effect of this ſtate of the metropolis upon the health of the inhabitants, by conſidering the nature of the diſeaſes which were then prevalent, as well as the comparative mortality of thoſe, and of our own times. In the early part of our hiſtory a great number of years are ſpecified as plague-years. (See the City Remembrancer.) In the 14th, 15th, and 16th centuries, there ſcarcely paſſed ten years without a conſiderable plague: and although only four great plagues are commonly mentioned in the 17th century, *viz.* in the years 1603, 1625, 1636, and 1665; yet Maitland, in his Hiſtory of London, declares that for five and twenty years before the great fire of 1666, the city had never been clear from the plague; and from the year 1603, when the regiſter begins, till 1670, the bills of mortality exhibit only three years entirely free. The other diſeaſes, which were frequently epidemic in London, were ſuch as commonly originate in ſwampy countries and in camps, namely, intermittent, remittent, and ſpotted, or malignant fevers, and dyſentery. Of the great prevalence of theſe diſeaſes, down to the time of the great fire in 1666, we have already given ample evidence. See EPIDEMIC.

On the other hand, the progreſſive improvement in the public health, will be found to be not leſs manifeſtly ſynchronous with the refinements in the arts of life, and the improvements in the economy of the metropolis, if we compare the varying progreſs of the annual mortality, as exhibited in the bills.

Soon after the great fire of 1666, the plague altogether ceaſed, and has never ſince recurred; but the other epidemics above mentioned, although ſomewhat diminiſhed in numbers, ſtill occurred to a great and fatal extent; ſo that, in proportion to the actual population, the annual mortality was excedingly great. This will appear in ſtrong colours, when it is ſtated that the actual mortality was greater at the beginning of the 18th century, than at the end of it, notwithſtanding the great increaſe both in the number and extent of the out-pariſhes, included in the bills of mortality. The annual average of deaths in the firſt ten years of the century was *twenty-one thouſand* and upwards; in the laſt decade of years, only *nineteen thouſand* and upwards. The mortality and quantity of diſeaſe, in proportion to the population, therefore, was incalculably greater than at preſent. The principal amelioration in the health of the metropolis, however, ſeems to have been more particularly brought about within the laſt ſixty years. Until nearly the middle of the laſt century, the mortality kept pace, in ſome meaſure, with the increaſing population; for, in the 3d and 4th decades, that is, from 1720 to 1740, the annual average of burials was from twenty-ſix to twenty-eight thouſand; and the deaths in 1741, were *thirty-two thouſand!* (See the Bills of Mortality.) From this time the diminution of the mortality has been progreſſive, and in the paſt year, 1809, it amounted to 16,680 only.

It will be recollected, that, although very conſiderable improvements were made in the city, when it was rebuilt after the conflagration of 1666, yet it continued highly incommodious, and retained many of its unſalutary peculiarities, for a century afterwards. For it was not until the year 1766, that the example of reform, which had been ſet by the inhabitants of Weſtminſter, was adopted by parliamentary ſanction in the city. Fleet ditch was then firſt covered in; the ſtreets were paved with large ſquared ſtones; the ſigns, gates, and bars were taken down, and a free ventilation admitted; openings were made in the incommodious parts of the ſtreets; and the accumulation of filth and other ſources of miaſmata farther prevented by the more active employment of ſcavengers, the increaſed ſupply of water, &c.; which ſyſtem has been purſued, and is ſtill continued, to the great ornament of the metropolis, as well as to the ſubſtantial benefit of its inhabitants. From this time, the remittent and intermittent fevers and dyſentery rapidly diminiſhed in frequency and fatality; the two former now ſcarcely ever originating in London, and the latter being ſeldom general or epidemic. Malignant fevers became leſs prevalent in gaols, and in the cloſe habitations of the poor; and Newgate is no longer viſited by its annual typhus, which is now ſeldom found committing its ravages, even in the abodes of poverty.

On the whole, then, it muſt be inferred, from this detail of facts, that the health of the inhabitants of London (as well as of other large cities) is greatly dependent on its phyſical and moral condition; and that the improvements in civilization conduce no leſs to the length and value of life, than to the increaſe of its comforts, and to the general well-being of the ſocial ſtate. To the public and external changes in the condition of the metropolis, we are indebted for our preſent freedom from the endemic and epidemic diſeaſes of camps; *viz.* the intermittent and remittent fevers, dyſentery, and the plague: and to the alterations in our domeſtic economy, in regard to ſituation, ventilation, and cleanlineſs, we owe our exemption from the contagious diſeaſes of gaols, and other crowded and cloſe ſituations, *viz.* typhous and malignant fevers.

Influence of the Seaſons on Health.

One of the moſt extraordinary reſults of the improvements, above alluded to, and one which could not have been anticipated, is the total change of the character of the ſeaſons, as to their influence on health, a change which greatly illuſtrates the doctrine juſt laid down, as well as the nature of what were formerly termed the "epidemic conſtitutions" of the atmoſphere. It has been already obſerved, that epidemic diſeaſes in general have only occurred during particular ſeaſons; and that in the various countries of Europe, the autumn and the end of ſummer have been moſt productive of thoſe diſeaſes. From July to the end of September the plague has generally been moſt deſtructive, not only in London, but at Moſcow, Montpelier, and other places. (See EPIDEMIC.) The ancient phyſicians all remarked the great inſalubrity of the ſummer and autumn, and the comparative healthineſs of the ſpring. Celſus has characterized the four ſeaſons in theſe terms: "Igitur ſaluberrimum ver eſt; proxime deinde ab hoc, hiems; periculoſior æſtas, autumnus longe periculoſiſſimus." (De Medicinâ. lib. ii. cap. 1.) "The ſpring is the moſt healthy ſeaſon, and next to it the winter; the ſummer is more dangerous than theſe, but the autumn is by far the moſt dangerous." Now this obſervation is ſtill in a great meaſure true in the ſouthern climates of Europe, on the borders of the Mediterranean, where the ancient phyſicians practiſed, as well as at Montpelier, &c.; and ſir John Pringle remarks, that "the ancient maxim that held 'the ſummer and autumn to be the

the moſt ſickly ſeaſons,' is not only verified with reſpect to the warmer climates, but alſo to *a camp*." (On Diſeaſes of the Army, part ii. chap. 1.) The ſame obſervation *was* true, in regard to this country, and to London and the larger towns in particular, during the 17th and the beginning of the 18th centuries; as we learn from the writings of Sydenham, as well as from the publications relating to the bills of mortality by major Graunt, who wrote about the middle of the former century, and obſerved, that "the unhealthful ſeaſon is the autumn." (See his Nat. and Polit. Obſ. on the Bills of Mortality, p. 56, edit. 5.) The obſervation continues to be applicable to the ſouthern latitudes, becauſe, during the heat of ſummer thoſe perſons who are neceſſarily expoſed to the rays of a burning ſun, often ſuffer by its direct influence; but ſtill more ſo, becauſe the rains which fall in the autumn upon the long heated ground, occaſion the generation of miaſmata, wherever the ground is flat, or the ſoil copious, or naturally ſwampy. Under ſuch circumſtances a "malaria," or *bad air*, as it is popularly termed in Italy, is generated, and endemic diſeaſes ariſe in conſequence. (See Irvine on the Diſeaſes of Sicily, p. 6.) The obſervation is ſtill applicable to camps, during the ſummer and autumn, in conſequence of the miaſmata, which the heats of thoſe ſeaſons generate and cauſe to evaporate from the foul and moiſt ſoil, which is neceſſarily occaſioned by the impurities before mentioned, eſpecially when a camp is for any length of time ſtationary. But in this temperate climate, where theſe ſources of the poiſonous miaſmata have been prevented, by the plans already deſcribed, the obſervation is ſo far from being verified now, that the healthineſs of the ſeaſons is nearly reverſed; or, in other words, that the moſt healthy ſeaſon of our forefathers, the ſpring, (which remains at leaſt as healthy as heretofore,) is now the moſt ſickly of our ſeaſons. There is no doubt, indeed, that in conſequence of the improvements before mentioned, the ſpring is actually more healthy than formerly; for vernal agues are conſtantly ſpoken of by Sydenham and others; whereas they are abſolutely unknown to us at preſent in London. The inference is, then, that *the moſt ſickly ſeaſon of our own times is actually productive of leſs diſeaſe than the moſt healthy ſeaſon was a century ago:* a circumſtance which enables us to account for the great comparative diminution of the annual mortality in London, as evinced by the preſent bills. Dr. Heberden ſhews that "the whole number of deaths is greateſt in January, February, and March; and leaſt in June, July, and Auguſt;" (loc. cit. p. 46.) and that February, in proportion to its length, is the moſt fatal month of the 12. At York the ſeaſons were fatal in the following ratio, according to the obſervations of Dr. White, during ſeven years; the number of burials being in the winter months, November, December, and January, 842; in the ſpring, February, March, April, 875; in the ſummer, May, June, July, 759; in the autumn, Auguſt, September, and October, 699; which ſeries is exactly the reverſe of that which Celſus has ſtated, autumn being here the moſt healthy, and ſpring the leaſt: whereas at Montpelier the ancient ſeries is ſtill exemplified; the number of deaths in that city during the five months, from July to November incluſive, being nearly equal to the whole number of the remaining ſeven months. (See a table quoted from the Mem. de la Soc. Roy. de Medicine, ann. 1777 and 1781. Heberden, p. 49.)

The influence of the different ſeaſons of the year on the health of mankind, may, therefore, be referred to the intrinſic and ſenſible conditions of the ſurrounding atmoſphere on the one hand, and to its adventitious qualities on the other: the latter conſtituting its "epidemic conſtitutions," and giving riſe to ſome of the moſt general epidemic diſeaſes; while the former produce chiefly ſporadic, and leſs prevalent complaints.

Sydenham, being unable to detect the connection of the epidemic conſtitutions of the atmoſphere with its ſenſible qualities, conjectured that certain exhalations from the bowels of the earth impregnated the air with deleterious powers. From the preceding details it would appear, that that ſagacious phyſician erred only in aſcribing thoſe exhalations to the bowels inſtead of the ſurface of the earth. But thoſe perſons undoubtedly erred ſtill farther, who attributed the prevailing diſeaſes to a general contamination of the atmoſphere, brought from afar, and ſpreading widely around; ſince theſe maladies originated from an impregnation received upon the ſpot, a poiſonous exhalation which that portion of the air, immediately encompaſſing the place where they raged, drank up from human or other impurities. In hot climates, where the long and intenſe heat, combined or ſucceeded by autumnal rains, muſt continue to generate miaſmata from the ordinary ſoil, theſe epidemic diſeaſes will continue to recur; the yellow fever will ſtill be known in St. Domingo and Surinam, and remittent fevers and ague in the marſhes of Walcheren. But in the dry and temperate countries of northern Europe, by preventing the adventitious impregnations of the atmoſphere, that is, by removing the medium through which the heat and moiſture of ſummer and autumn operate upon the air, the influence of the ſeaſons on health may be reduced to the direct operation of the ſenſible properties of the air, (its heat, cold, and moiſture,) upon the human frame.

Hence, then, it is obvious, why the winter and ſpring are now become the moſt unhealthy ſeaſons in this country. For in this temperate climate, the *heat* is ſeldom ſo great as to produce any direct ill effect in the ſummer and autumn; and the remaining atmoſpheric qualities of *cold* and *moiſture*, which prevail in the two former ſeaſons, are, therefore, the only active agents in exciting diſeaſes, ſo far as the ſeaſons are concerned. To theſe agents we ſhall briefly attend at preſent, referring an account of the direct effects of heat to its proper head. See HEAT, in *Medicine*.

The diſeaſes which are moſt generally prevalent during the cold ſeaſons, winter and ſpring, and which are univerſally known to originate from the influence of cold, are chiefly inflammatory diſeaſes affecting the organs of reſpiration; ſuch as the common catarrh, the winter-cough with dyſpnæa, pleuriſy, peripneumony, aſthma, ſpitting of blood, and conſumption. To theſe we may add the numerous modifications of rheumatiſm, lumbago, ſciatica, &c. inflammatory affections of the throat; and diſorders of the bowels. It will be found, on referring to the liſts of diſeaſes, which are obſerved at the public medical inſtitutions of London, that the pectoral complaints alone conſtitute upwards of one-third of all the diſeaſes occurring in the cold ſeaſons; and together with the rheumatic affections, &c., upwards of one half. (See Dr. Willan's Reports on the Diſeaſes of London; and the Reports of the Diſeaſes treated at the Public Diſpenſary, Carey-ſtreet, by the writer of this article, in the Edinburgh Med. and Surg. Journal, from the year 1805, downwards.) Now it has been calculated upon well-founded documents, that pulmonary conſumption alone deſtroys about one in ſix, of thoſe who die in this country, or about 55,000 perſons annually. (See Dr. Woolcombe's Remarks on the Frequency and Fatality of different Diſeaſes, 1808.) And when, in addition to this, we reflect

that

that a great number of aged people are cut off by aſthma, and by the winter-cough, ſo that "of thoſe aged above 60 years by much the greateſt number die in the coldeſt months, and the feweſt in the middle of ſummer," (Heberden,) the fatal effects of the cold ſeaſons will be very obvious. We have already ſtated ſeveral facts and authorities, which completely prove the fallacy of the popular opinions, that there is ſomething wholeſome in a ſharp froſt, and that "a green winter makes a fat church-yard." (See COLD, under ſect. II. *Its effects in producing diſeaſes*.) The fact is directly the reverſe, as the ſtatements there adduced will evince. In addition to the references there made, ſee Dr. Heberden on the Increaſe, &c. of Diſeaſes, pp. 55 and 58. Edin. Med. and Surg. Journal, vol. iii. p. 247.

The connection of ſcrofula with the cold and humidity of our climate is likewiſe very obvious; eſpecially in the conſtitution of thoſe young people, who are natives of a warmer latitude. Mr. Pearſon, who ſuperintended an eſtabliſhment for African children, brought over to this country for education, by the Sierra Leone company, ſtates, they all became ſcrofulous or conſumptive, and died in the latter ſtate. "It is remarkable," he obſerves, "that boys brought from tropical climates, from the age of eight to 12, almoſt uniformly become ſcrofulous. They bear the firſt winter tolerably well, but droop during the ſecond, and the third generally proves fatal to them." The conſumptive ſymptoms were ſometimes preceded by ſwelling and ſuppuration of the glands, enlargement of the bones, &c.; but, in females particularly, conſumption was often the primary complaint. Theſe fatal effects of the climate rendered it neceſſary to abandon the plan. It cannot be doubted, we apprehend, that the deluſive attempts to *harden* the conſtitution of children, born in this climate, by thin clothing, conſtant expoſure to the cold air in winter, &c., are very analogous to the influence of a new climate upon the African children; for the perfect and healthy evolution of the animal ſyſtem is thus prevented; and the foundation is laid for ſcrofula, conſumption, and other chronic diſeaſes. See Ann. Med. Rev. vol. ii. 1809, p. 130.

Influence of Manufactories, &c. on Health.

Among the various operations, ſubſervient to the arts and manufactures of modern times, there are many which contribute to diffuſe in the atmoſphere certain effluvia or vapours, ſome of which are diſagreeable in their ſmell, or difficult to reſpire, and others, though not ſo obvious to the ſenſes, are nevertheleſs prejudicial to health. On the whole, however, the public health is not much affected by ſuch effluvia. For, in the firſt place, a diſagreeable ſmell is by no means a certain criterion of an unwholeſome atmoſphere; and, in the ſecond, the volatilization of poiſonous metals by fire, which conſtitutes one of the moſt probable means of contaminating the air, may be ſo managed, by connecting with the works proper chimnies, and other condenſing apparatus, as to obviate altogether the danger which might thence ariſe to the public. Many miſtakes have been committed by writers on this ſubject, and conſiderable difference in principle has been manifeſted in legal deciſions reſpecting the degree of nuiſance in ſuch caſes. In the 17th century the ſmoke from coal-fires was deemed, both by natives and foreigners, one of the principal cauſes of the unhealthineſs of London. This was ſtated in ſtrong terms by major Graunt (Obſ. on Bills of Mortality, fifth edit. p. 95.); and Evelyn, who publiſhed a pamphlet in 1661, entitled "Fumifugium," indignantly laments the "clouds of ſmoke and ſulphur, ſo full of ſtink and darkneſs," in which this glorious and ancient city wraps her ſtately head; and he affirms, that in the year 1664, when Newcaſtle was beſieged, and coals not to be procured in London, "divers gardens and orchards, planted in the very heart of London (as, in particular, my lord Marquiſſe of Hartford's, in the Strand, and my lord Bridgewaters', and ſome others, about Barbican), were obſerved to bear ſuch plentiful and infinite quantities of fruits, as they never produced the like, either before or ſince, to their great aſtoniſhment." In refutation of ſuch notions, however, it is ſufficient to remark, that while this ſuppoſed cauſe of unhealthineſs has been augmented to an incalculable degree, the actual condition of the metropolis, in point of ſalubrity, has been greatly improved.

In like manner, the manufactories, in which various effluvia are diſengaged from animal and vegetable matters, in conſequence of putrefaction or fermentation, are no longer prejudicial to the public health, when they are conducted with care and prudence. Thus in breweries, in ſtarch and colour manufactories, as of turnſol and indigo, in paper-mills, &c. the fumes, which ariſe from the fermenting and decompoſing matters, can be dangerous only to thoſe employed about the works, and in the immediate vicinity of the veſſels and apparatus. They ceaſe to be deleterious the moment they are diffuſed and combined with the external air, and cannot affect the inhabitants of neighbouring dwellings. Even where animal matters are liable to putrefy, as in the manufactories of cat-gut, tanneries, and ſlaughter-houſes, the effects of theſe corrupted exhalations, which, when diffuſed in the neighbourhood, form an atmoſphere very diſagreeable to breathe, may be obviated by proper care. Moſt commonly ſuch putrefaction is not neceſſary to the operations going on, and only occurs from the animal ſubſtances being allowed to remain too long in the manufactory, or in too high a temperature. It is only neceſſary, therefore, to cauſe the materials to be frequently renewed, in order to prevent their corruption, and to keep the place clean. In this reſpect ſlaughter-houſes are attended with ſome inconvenience; but this is by no means of ſo ſerious a nature as to demand their baniſhment without the limits of cities. A ſlaughter-houſe, indeed, when the filth and blood are collected in heaps to putrefy, is peſtilence itſelf; but when the offals are regularly removed it ceaſes to be a nuiſance. Hence a little attention on the part of the magiſtrate, that butchers do not throw out the blood and refuſe of the animals which they kill, nor ſuffer them to accumulate, is ſufficient to obviate any diſguſting and unhealthy effects ariſing from ſlaughter-houſes.

Of the manufactories in which effluvia are driven off by fire, thoſe of the mineral acids, which were formerly deemed extremely injurious, have been found by experience to be deſtitute of danger; and even thoſe effluvia, which are diſengaged in the preparations of mercury, lead, copper, antimony, and arſenic, and are all ſomewhat dangerous to thoſe who inhabit and aſſiſt in the works, can only injure thoſe who reſide in the neighbourhood, when proper chimnies, that may convey the vapours out of the reach of reſpiration, or condenſe them, are omitted to be uſed. Hence the magiſtracy ought chiefly to confine its attention to the adoption of theſe meaſures of precaution, and to direct ſcience towards the improvements of which theſe proceſſes are ſuſceptible with regard to health, inſtead of haſtily baniſhing theſe manufactories from their cities. (See a Report of the Nat. Inſtitute of Paris, 1806, Annales de Chimie, tom. liv. p. 86.—Alſo, in the Edinburgh Med. and Surg. Journal, vol. ii. p. 290.) See NUISANCE.

The preſervation of the public health, then, as appears from the foregoing ſtatements, is greatly dependent upon a ſyſtem of cleanlineſs and ventilation, carried on upon an extenſive ſcale

ſcale throughout ſociety; and this ſyſtem has effected what quarantines, peſt-houſes, &c. in vain attempted to accompliſh. Indeed, from the conſtant exiſtence of the plague in London during the 17th century, it can ſcarcely be ſuppoſed to have been *imported* at the particular periods when it raged ſo deſtructively; and, on the other hand, our quarantine laws, however rigid and ſevere they may be, are by no means adequate to the excluſion of all contagion. (See Howard on Lazarettos; Heberden on Increaſe, &c. of Diſeaſes.) But the laſt mentioned author obſerves, "That the plague was ever actually bred in London, it might be odious to aſſert, and would be impoſſible to prove; yet, to any one who reflects upon its frequent returns in this capital until the latter end of the 17th century, and its total abſence ſince, notwithſtanding the great increaſe of our trade, by which it was ſuppoſed to be imported, it muſt, I think, appear probable, that if its origin were derived from foreign contagion, at leaſt its propagation ought, in a great meaſure, to be attributed to ſome prediſpoſition of the town in thoſe days, which has ſince been corrected." p. 69.

The moſt ancient mode of preventing the progreſs of contagious diſeaſes, was the ſeclufion of thoſe already infected and labouring under the diſeaſes, from the reſt of the community; but this practice ſeems to have been applied principally, in early times, to chronic contagions, or chronic diſorders believed to be contagious, ſuch as the leproſy. In more recent times the principle has been adopted with reſpect to peſtilential epidemics, whence the inſtitution of lazarettos, peſt-houſes, &c. and more lately of fever-houſes, or houſes of recovery, as they have been called, with a view to the prevention of common typhus, or contagious fever. It is poſſible that a vigorous activity of the police, in diſcovering and clearing the houſes firſt infected by the plague, by removing the ſick to a peſt-houſe, might ſuppreſs a naſcent peſtilence; but when we reflect on the total inefficiency of ſuch eſtabliſhments hitherto uſed (as in the laſt plague at Marſeilles, &c.), and on the probable origin of thoſe epidemics, in the firſt inſtance, from filth, however propagated afterwards by contagion, we cannot aſcertain any confident hope of ſucceſs from ſuch expedients. See PLAGUE.

The inſtitution of houſes of recovery for the ſuppreſſion of typhus, during a ſeaſon of comparative health, appear to be, and have actually been found to be, moſt beneficial means of preſerving the public from the influence of malignant fevers. By being conſtantly on the watch, and immediately extinguiſhing, in its birth, the firſt germ of contagion where it originates, and purifying the ſource of its generation, the general prevalence of infectious fevers may perhaps be effectually prevented, and epidemics of this nature baniſhed from ſociety. Such hopes, the ſucceſs of thoſe inſtitutions, hitherto eſtabliſhed in the populous cities of England and Ireland, is calculated to encourage in the higheſt degree. See HOUSE of *Recovery*.

For theſe epidemic diſeaſes, by which the public health is at times extenſively and fatally deſtroyed, and which appear to originate, not in miaſmata or in the effluvia from the human body in confined ſituations, but in a ſpecific contagion (ſuch as the ſmall-pox, meaſles and ſcarlet-fever), the means of public ſecurity are not ſo much within our reach. For the two laſt mentioned maladies, indeed, we know of no preventive means; ſo that the inhabitants of large cities muſt probably undergo them once in the courſe of life. But, for the ſmall-pox, the direct peſtilence that viſits mankind, a method of amelioration has been reſorted to, for nearly a century, in Europe, by which the lives of multitudes have been preſerved, but by which alſo death has been inflicted upon multitudes of others, whom prejudice, careleſſneſs, or miſinformation, have led to neglect the employment of the preventive, ſince it has been an artificial ſource of continued contagion; we mean inoculation. Similar prejudice, negligence, or miſtaken views, continue to be fatal to the public health, by encouraging the propagation of this dire contagion, even after an experience of twelve years has eſtabliſhed the efficacy of the invaluable diſcovery of Dr. Jenner, the COW-POCK, in ſuperſeding the influence of ſmall-pox, while it does not contribute to generate any contagion which may injure the health of others. When theſe unfortunate errors in public opinion ſhall be removed, and vaccination ſhall be generally received, the public health will have attained a degree of perfection and permanency, beyond which, perhaps, it cannot be expected to advance, while the paſſions, wants, and occupations of men neceſſarily expoſe them to various cauſes of diſeaſe.

Injuries, affecting a man's health, conſidered in a *legal* view, are thoſe in which, by any unwholeſome practices of another, he ſuſtains any apparent damage in his vigour or conſtitution; as by ſelling him bad proviſions or wine, by the exerciſe of a noiſome trade, or by the neglect or unſkilful management of his phyſician, ſurgeon, or apothecary. For theſe injuries there is a remedy in damages by a ſpecial action of treſpaſs upon the caſe. The ſtat. 51 Hen. III. ſtat. 6. prohibits the ſale of corrupted wine and unwholeſome fleſh, or fleſh bought of a Jew, under pain of amercement for the firſt offence, pillory for the ſecond, fine and impriſonment for the third, and abjuration of the town for the fourth; and by ſtat. 12 Car. II. cap. 25. any brewing or adulteration of wine is puniſhable with the forfeiture of 100*l.* if done by the wholeſale merchant, and 40*l.* if done by the vintner or retailer. See PLAGUE and QUARANTAIN.

The ancients perſonified, and even deified, health; or, rather, they erected a goddeſs, to whom they ſuppoſed the care of health to belong. The Greeks worſhipped her under the name of Υγεια, and the Latins under that of *Salus*. The place of her worſhip at Rome, was on the Mons Quirinalis, where ſhe had a temple, and a ſtatue crowned with medicinal herbs.

We frequently find the goddeſs Health on the reverſe of medals. She is repreſented crowned with laurel, with a ſerpent ſtretched on her left arm, and holding a patera to it with the right. Sometimes ſhe has an altar before her, with a ſerpent twiſted round the ſame, and raiſing its head to take ſomething off from it.

HEARGUET, a town of Candahar; 12 miles W. of Ghizni.

HEARING, AUDITUS, the act or faculty of perceiving ſounds. Hearing is reckoned among our external ſenſes. Its organ is the *ear*, and particularly the auditory nerve diffuſed through the ſame; and its object, certain motions or vibrations of the air.

Hence hearing may be more ſcientifically defined, a ſenſation, whereby, from a due motion impreſſed on the fi-

brillæ of the auditory nerve, and communicated thence to the ſenſory, the mind perceives, and gets the idea of ſounds.

The moderns ſpeak of the point on much better ground.

The ear, and the ſeveral parts thereof, membranes, canals, labyrinths, nerves, &c. are the only means and vehicles for the reception, modification, and tranſmiſſion of the ſonorous matter to the brain, which is the ſeat of the ſenſe.

A ſound, in effect, is nothing but a certain rarefaction or modulation of the external air, which, being gathered by the external ear, paſſes through the meatus auditorius, and beats upon the membrana tympani, which moves the little bones in the tympanum. For a deſcription of the bones of the organ of hearing, ſee CRANIUM.

In like manner, as this is beat by the external air, theſe little bones move the internal air which is in the tympanum and veſtibulum; which internal air makes an impreſſion upon the auditory nerve in the labyrinth and cochlea, according as it is moved by the little bones in the tympanum: ſo that, according to the various refractions of the external air, the internal air makes various impreſſions upon the auditory nerve, the immediate organ of hearing; which different impreſſions repreſent different ſounds. For a more particular ſcientific account of the organ and ſenſe of hearing, ſee EAR.

Sir Iſaac Newton carries the thing ſomewhat farther, and ſuppoſes hearing, like ſeeing, to be performed not immediately by the vibrations of the ear, but by thoſe of ſome other more ſubtile medium, excited in the auditory nerves by the tremors of the air, and propagated through the ſolid capillaments of the nerve to the place of ſenſation.

The curious ſtructure of the labyrinth and cochlea tend to make the weakeſt ſounds audible; for the whole organ of hearing having been included in a ſmall ſpace, had the auditory nerve run in a ſtraight line, the impreſſion would only have been made on a very ſmall part of it; and the ſtrength of the impreſſion being, *cæteris paribus*, always as the number of parts on which the impreſſion is made, ſounds which are now low could not have been heard at all. If the auditory nerve had, like the retina, been expanded, into a large web, which had covered or lined ſome wide cavity, the impreſſion of ſounds, even in this caſe, had been much weaker than they are now; for this large cavity had given room for the ſounds to dilate, and all ſounds grow weaker as they dilate.

Both theſe inconveniences are prevented by the preſent ſtructure of the labyrinth and cochlea, whoſe canals, by their winding, contain large portions of the auditory nerve, upon every point of which the ſmalleſt ſound being at once impreſſed becomes audible, and by their narrowneſs the ſounds are hindered from dilating; and the impreſſions made upon the nerves by the firſt dilatations are always the ſtrongeſt.

The ſtrength of the impreſſion in narrow channels is likewiſe increaſed on account of the elaſticity of the ſides of the bony canal, which, receiving the firſt and ſtrongeſt impulſes of the air, do reverberate them more ſtrongly upon the auditory nerve.

It may be obſerved, that though the air be the uſual matter of ſounds, ſo that a bell rung in vacuo is not heard at all, yet will moſt other bodies, properly diſpoſed, do the like office, only ſome more faintly than others.

Thus may a ſound be heard through water, or even through earth; of which we have various inſtances.

Although the ear be the ordinary organ of hearing, yet Hagerup, a Daniſh phyſician, maintains that one may hear with the teeth. Thus, if one end of a knife, or the like, be applied to a harpſichord, and the other held between the teeth, the muſic thereof will be plainly heard, though the ears be ever ſo cloſely ſtopped. But this, perhaps, may more properly be referred to the ſenſe of feeling.

Such as want the ſenſe of hearing are ſaid to be deaf. See DEAFNESS.

HEARING, *Difficulty of.* See DEAFNESS.

HEARING is particularly uſed in civil and judicial concerns, for a cauſe being brought before the judge and jury, and the parties being heard as to the merits thereof.

The method of hearing cauſes in the court of Chancery is this: the parties on both ſides appearing by their counſel, the plaintiff's bill is firſt opened or briefly abridged, and the defendant's anſwer alſo, by the junior counſel on each ſide; after which the plaintiff's leading counſel ſtates the caſe and the matters in iſſue, and the points of equity ariſing from them; and then ſuch depoſitions as are called for by the plaintiff are read by one of the ſix clerks; and the plaintiff may alſo read ſuch part of the defendant's anſwer as he thinks material or convenient: and, after this, the reſt of the counſel for the plaintiff make their obſervations and arguments. Then the defendant's counſel go through the ſame proceſs for him, except that they may not read any part of his anſwer; and the counſel for the plaintiff are heard in reply. When all are heard, the court pronounces the decree, adjuſting every point in debate according to equity and good conſcience; which decree, being uſually very long, the minutes of it are taken down, and read openly in court by the regiſtrar. Blackſt. Com. vol. iii. p. 451. 4to.

The hearing of ambaſſadors at the courts of princes, is uſually called *audience*.

HEARNE, THOMAS, in *Biography*, was born at White-Waltham, in Berkſhire, in 1680, of which place his father was pariſh clerk. The early part of his education he received under his father, but ſhewing a diſpoſition for learning, he was patronized by Francis Charney, eſq. who undertook the charge of his education, and ſent him to Oxford. Here he acquired from his tutors a taſte for antiquities, reſearches to which he had been addicted from his youth. He was ſelected by Dr. Mill and Dr. Grabe as a fit perſon to collate the MSS. which they had occaſion to make uſe of. He took his degree of B. A.; refuſed a curacy which was offered him, and was in time made ſecond librarian of the Bodleian library. To this were added ſome other college offices, all which he reſigned when he was called on to take the oaths to George I. which he felt obliged conſcientiouſly to refuſe. He died in 1735, having been the editor of 38 works, chiefly ſuch as relate to the hiſtory and antiquities of England, though he did not confine his labours to theſe, but gave the world new editions of Pliny the younger, Eutropius, Juſtin, and Livy. To the article in the Biog. Brit. there is ſubjoined a liſt of his works. He continued a nonjuror to the laſt, and notwithſtanding the ſmallneſs of his means, he had contrived, by parſimony, to ſave 1300*l.* in caſh, which was found among his books and papers at his death.

HEARSAY EVIDENCE. See EVIDENCE.

HEARSE, among *Hunters*, a hind in the ſecond year of her age. See HUNTING.

HEARSE is the name of a well known carriage, uſed for conveying the dead to the grave.

The word is alſo uſed by Shakſpeare in his Henry VI. for a monument erected over a grave.

HEART, in *Anatomy*, a muſcular organ, ſituated in the

the cheſt, and affording, by its contractions, the chief power by which the circulation of the blood is carried on.

Under the article ARTERY a general account of the ſtructure and functions of the arterial ſyſtem is delivered; and a general view of the CIRCULATION will be found under that word. We propoſe to complete the view, both of the ſtructure and offices of the circulating organs, in the preſent article. For this purpoſe we ſhall adopt the repreſentations of Bichat in his Anatomie Generale, following the general arrangement of the ſubject, exhibited in that work. As the ſtructure of the heart admits of deſcription moſt conveniently, when it is viewed as a ſingle organ, we ſhall defer the conſideration of its anatomy to the concluſion of the general deſcription of the circulation. We ſhall alſo include an account of the capillary and exhaling ſyſtems of veſſels.

"All authors (ſays Bichat, Anatomie Generale, t. 2.) who have written on the circulation ſince the time of Harvey, have deſcribed it in the ſame manner, dividing this function into two parts, the great, and the leſs or pulmonary circulations, of which the heart is the common centre. This mode of conſidering the ſubject does not lead us to obſerve, in a general manner, the objects of the blood's motion through our organs; and I deem the mode, in which I explain this important phenomenon of the animal economy in my lectures, infinitely better calculated to convey a correct notion of its nature. I divide the circulation into two parts; one of which carries blood from the lungs to all parts of the body, the other brings this fluid back again from all parts to the lungs. The firſt of theſe is the circulation of red blood, the ſecond that of black blood.

Circulation of Red Blood.—This has its origin in the capillaries of the lungs, where the action of the air on the blood gives it thoſe characters which diſtinguiſh it from the ſame fluid in its black ſtate. From theſe capillaries it paſſes ſucceſſively through the branches and trunks of the pulmonary veins, and the left auricle, into the left ventricle of the heart, which propels it into the arterial ſyſtem. The latter conveys it into the general capillary ſyſtem (the capillaries of the body at large, excepting thoſe of the lungs), which muſt be regarded as the termination of its courſe. Thus the red blood is conſtantly conveyed from the capillary ſyſtem of the lungs to that of the body in general. The cavities, which contain this blood, are all lined by a continuous membrane, which being expanded over the pulmonary veins, the left cavities of the heart, and the arterial ſyſtem, may with truth be conſidered to form an unbroken canal, ſtrengthened on its exterior, in the pulmonary veins by a ſoft membrane, in the heart by a muſcular layer which is thin in the auricle, and thick in the ventricle, and in the arterial ſyſtem by a fibrous layer of peculiar texture. In all theſe various organs, which are added to it externally, the membrane itſelf remains nearly the ſame.

Circulation of Black Blood.—The courſe of this is inverſe to that of the preceding. It begins in the general capillary ſyſtem, and here the blood which it contains acquires its diſtinctive characters: here, if we may uſe the expreſſion, it ſeems to be reproduced, probably by the ſubtraction of thoſe principles, which it had previouſly derived from the atmoſphere in the lungs. From the general capillary ſyſtem it paſſes into the veins, which bring it to the right cavities of the heart: thence it is tranſmitted through the pulmonary artery to the capillary ſyſtem of the lungs. The latter is its true termination, as it is the commencement of the ſyſtem containing the red blood. One general membrane, continuous throughout, lines the whole paſſage of the black blood, and forms for it an unbroken canal, along which it is conſtantly conveyed from all parts of the body to the lungs. On the outſide of this canal there is placed a looſe membrane in the veins, a muſcular ſtratum in the heart, and a peculiar fibrous tiſſue in the pulmonary artery: but the membrane, as in the preceding caſe, remains always nearly uniform, in ſpite of the various organs which ſurround it externally. The folds of this membrane form the valves of the veins: it alſo aſſiſts in the compoſition of the valvular apparatus belonging to the right ſide of the heart, of which it lines the cavities; as the membrane of the other circulation concurs in forming the valves and lining the correſponding parts on the left ſide of the heart

Differences of the two Circulations.—The general idea, which I have thus given of the two circulations, ſhews plainly that they are perfectly independent of each other, except at their origin and termination, where the red and black blood are alternately changed into the oppoſite ſtates, and communicate, for this purpoſe, by the capillary veſſels. In the whole of their courſe the two circulations are completely iſolated. Although the two ſides of the heart are united together in a ſingle organ, they may be regarded as perfectly independent in their motion. There are in truth two hearts, a right and a left: they might probably perform their functions juſt as well, if they were ſeparated, as in their preſent connected form. Even when the foramen ovale remains open after birth, we ſhall prove afterwards that the ſtructure of its ſides prevents all intermixture of the red and black bloods, and conſequently the two parts are ſtill equally independent, as far as regards the courſe of the blood. This complete ſeparation of the two circulations is one of their moſt decided characters; and it alone ſhews, how preferable the point of view, in which I regard the circulation, is to that in which it is repreſented as divided into the great and leſs, which are manifeſtly confuſed and identified with each other.

According to the obſervations already made, the two circulations begin and terminate in two capillary ſyſtems, which may therefore be conſidered as forming the limits within which the two kinds of blood circulate. In this point of view the lungs alone correſpond to all the other parts of the body. Their capillary ſyſtem is in oppoſition to that of all the other organs, with the ſmall exception of the parts from which the blood of the vena portarum proceeds. Thus each capillary ſyſtem is at once origin and termination: the pulmonary is the origin of the circulation of red; and the termination of that of black blood, while in the general the former ends and the latter begins. Hence ariſes a grand diſtinctive character of the two circulations: in fact, the blood not only follows an oppoſite courſe at the commencement and concluſion of the circulations, but it undergoes alſo a complete change in its nature; and in this reſpect the pulmonary and general capillary ſyſtems are the ſeat of the two moſt important phenomena of the animal economy, *viz.* the change of the blood from black to red, and *vice verſâ*. Each circulation evidently preſents three objects for our examination; 1ſt, the origin; 2dly, the courſe; 3dly, the termination of each kind of blood. In the firſt and laſt of theſe the mechanical phenomena of the circulation, and the transformation of the blood, require our conſideration; in the ſecond there are only the mechanical phenomena to be noticed.

General mechanical Phenomena of the two Circulations.—A general view of this ſubject exhibits to us; 1ſt, the red blood departing from the lungs, forming, as it proceeds, leſs numerous and more conſiderable columns, in proportion as it draws nearer to the heart, in the cavities of which it is ſeen in larger maſſes, and, as it paſſes from theſe to the general capillary ſyſtem, again dividing into ſmaller and ſmaller columns; 2dly, the black blood, accumulated, as it leaves the general ca-

pillary syſtem to approach the heart into fewer and larger columns, exiſting in the largeſt maſſes in the cavities of the heart, and again ſucceſſively ſeparated into ſmaller and ſmaller ſtreams as it arrives at the capillaries of the lungs. Thus the two kinds of blood circulate on the two ſides in ſtreams ſo much the ſmaller, as they are further from the heart; and they are ſeen in larger columns as they come nearer to this viſcus. Imagine for each of the two circulations two trees united by their trunks, and ſending their branches, the one into the lungs, the other into all parts of the body. Each of the two ſides of the heart is between theſe two trunks, which it ſerves to unite together ſo as to form one general canal, according to the deſcription already given.

Authors have generally repreſented the arteries and veins as forming each, by the whole of its ramifications, a general cone, of which the baſis is in all parts of the body, and the apex at the heart. This mode of conſidering the ſubject is authoriſed by the fact that the ſum of the branches exceeds in diameter the trunks from which they ariſe: in this point of view, each half of the heart is placed at the apices of two cones, which would, but for its intervention, be united together. The pulmonary veins repreſent one cone, and the aorta the other, for the red blood; while for the black, the two cones are formed by the venæ cavæ and coronary veins on one ſide, and by the pulmonary artery on the other. In each circulation one of the cones (that of the lungs) is remarkable for its ſmall extent; the other, (that correſponding to all parts of the body) is diſtinguiſhed by its wide expanſion.

Placed between theſe two cones, each ſide of the heart muſt be regarded as an agent of impulſion, driving the blood in one caſe towards all parts of the body, in the other towards the lungs. If the two cones of each circulation communicated together by their apices, the ſides of the veſſels compoſing them would be manifeſtly inſufficient to keep up the motion from the baſe of one to that of the other, that is, from the general to the pulmonary capillary ſyſtem, and reciprocally from that of the lung to that of the body at large. The courſe is obviouſly too long, and the vital powers of the veſſels too weak; hence the neceſſity of the heart. This conſequence renders neceſſary another arrangement, which we proceed to explain. As the red blood is deſtined to move through a much more extenſive ſpace, from the heart to the general capillary ſyſtem, than is traverſed by the black blood, in its paſſage from the heart to the pulmonary capillaries, that portion of the organ, which propels the fluid in the former caſe, muſt poſſeſs much greater power than is required for the purpoſe of keeping up motion in the latter inſtance. Nature has fulfilled this object, by compoſing the ventricle of the red blooded circulation of a much greater number of fibres than are poſſeſſed by the other. The auricles, which merely receive the blood, and tranſmit it into the ventricles, are nearly of the ſame thickneſs on both ſides of the heart.

Hence we may conclude, that the office performed by the heart in both circulations, relates merely to the mechanical phenomena of the blood's motion, and that if it produced any effect on the compoſition of the fluid, it could only be done by means of the motion imparted to it: ſecondly, that if the courſe of the two circulations were leſs extenſive, no intermediate impelling agent would not be neceſſary. This is preciſely the caſe in the abdominal ſyſtem of black blood, where the two trees, of which one diſtributes its branches in the gaſtric viſcera, and the other in the liver, are united by their trunks at the ſinus of the vena portarum, which occupies the poſition of the heart in the large ſyſtem of black blood, and in that of red blood. It is therefore poſſible to conceive, 1ſt, how the heart may be deficient, of which there are ſome inſtances, in which the two great circulating ſyſtems reſembled that of the abdomen, in ſome meaſure; 2dly, how the blood may oſcillate for a conſiderable time from one capillary ſyſtem to another, although the heart, diſeaſed and enfeebled, can hardly accelerate the current of this fluid; 3dly, how, after the pulſations of the heart have been entirely ſuſpended in ſyncope, aſphyxia, &c. an oſcillatory movement ſtill remains, a real progreſſion of the blood from one capillary ſyſtem to the other, ſince this fluid will ſtill flow in ſome degree from an opened artery or vein. This motion is in truth very feeble, and cannot laſt long; but that it may exiſt, without the influence of the heart, is proved by the fact of the black blood being conveyed, without any organ of impulſion, from the inteſtines to the liver; and hence we infer, that the ceſſation of the heart's action does not prove, as ſome authors have pretended, that the blood no longer moves; 4thly, we know that in ſeveral animals of the lower claſſes there is no heart, although diſtinct veſſels and circulating fluids exiſt.

General Uſes of the red-blooded Circulation.—This furniſhes the materials of all the ſecretions except the bile. From this ſource alſo the exhalants belonging to the ſerous, cellular, cutaneous, medullary, and other ſyſtems derive the fluids which they pour out on their reſpective ſurfaces. All the veſſels, which convey the means of nutrition and growth to the various organs of the body, are continuous with the arteries, and conſequently draw their fluids from the red blood. Even in thoſe parts, to which black blood is ſent, as the lungs and the liver, there are veſſels containing red blood; manifeſtly deſtined to fulfil the purpoſe of nutrition. The red blood communicates to all parts that general agitation or concuſſion (ſécouſſe) ſo neceſſary to the performance of their functions, and ſo clearly recognizable in the brain. Thus the red blooded circulation is the moſt important, and immediately concerned in the principal phenomena of the living economy.

General Uſes of the black-blooded Circulation.—The circulation of black blood, on the contrary, foreign to all the functions, ſeems to be deſigned merely to make good the loſſes which the blood has undergone in the preceding. A conſiderable portion of the red blood is expended in the functions of exhalation, ſecretion, and nutrition. The principles which it had received it its paſſage through the lungs, and which had given it a crimſon colour, have been left behind in the general capillary ſyſtem. The black blood muſt then receive again in proportion to what the red has loſt: hence a great number of matters is poured into the canal which contains it. Theſe are either interior or exterior. 1ſt. The large trunks of the abſorbing ſyſtem are conſtantly carrying in the lymph of the cellular ſubſtance and of the ſerous ſurfaces, the reſidue of the nutrition of all the organs, the ſuperabundant fat, ſynovia, and medullary matter. Every thing, which from the interior of the body is to be rejected outwards, is in the firſt place thrown into the black blood. 2dly. All which enters from without is firſt received into this circulation. The chyle, or the produce of the digeſtive functions, is conſtantly conveyed into the general canal, and circulates there. The gaſeous matters which traverſe the lungs in the act of reſpiration, are mingled with the blood in the ſame place. Laſtly, whenever abſorption takes place from the ſkin or the mucous membranes, the black blood firſt receives the product. Hence the circulation of black blood may be regarded as a general reſervoir, receiving in the firſt place all thoſe ſubſtances which are to be expelled from the body, and all which are to be admitted. In the latter point of view it performs a very important par-

part in diſeaſe. There can be no doubt, 1ſt, that deleterious ſubſtances may be introduced with the chyle into the circulation, and there produce, as they are carried round with the fluids, more or leſs decidedly pernicious effects. To produce this effect it is merely neceſſary that the organic ſenſibility of the lacteal veſſels ſhould be changed: they then admit what they before rejected, as, in conſequence of a ſimilar change, the glands often ſeparate fluids very different from their ordinary productions. 2dly. The cutaneous ſyſtem is often the ſeat of deleterious abſorptions. 3dly. Beſides the principles which impart colour to the blood, deleterious miaſmata probably often paſs through the lungs, and give riſe to diſeaſes. Thus the alimentary canal, the lungs and the ſkin are three inlets, through which, in many caſes, various morbific cauſes may enter the body: now all theſe are received at firſt into the black blood, and only admitted ſubſequently into the vaſcular ſyſtem which contains the red blood. A clear proof of the truth of this repreſentation may be derived, by introducing artificially into the black blood, thoſe ſubſtances which enter by natural paſſages; the phenomena obſerved in the former are completely analogous to thoſe exhibited in the latter caſe. Emetic or purgative infuſions, thrown into the veins, occaſion evacuations of the ſtomach and bowels, as when ſimilar ſubſtances are introduced into the body by frictions on the ſkin. The experience of numerous phyſiologiſts have completely eſtabliſhed this point. I am convinced that it is poſſible to communicate diſeaſes to animals by introducing various ſubſtances with their circulation through the veins.

From the foregoing account we may conclude, that the eſſential office of the circulation of black blood in the animal economy, is to introduce into this fluid various new ſubſtances; and that, on the contrary, the object of the other circulation is to expend or employ theſe matters. The maſs is conſtantly increaſing in the one, and diminiſhing in the other. Health ſuppoſes a perfect equilibrium between the loſſes of the red blood and the additions made to the black; whenever this is diſturbed, diſeaſe enſues. If the black blood receives more than the red expends, plethora is produced; and, in the oppoſite ſtate, the humours are ſaid to be impoveriſhed."

The preceding extract will ſhew the reader the new and intereſting point of view in which the important function of circulation is repreſented by Bichat: we ſhall proceed to a more detailed account of the matter, ſtill adhering to the arrangement, and making conſiderable uſe of the opinions of the French phyſiologiſt.

The Circulation of Red Blood.—The pulmonary veins which terminate ultimately in each lung, in two trunks opening into the left auricle, agree in their general ſtructure with the veins of the body at large, which will be conſidered in a future part of the article; they have however no valves. The circumſtances belonging peculiarly to theſe veſſels will be conſidered under LUNG. The auricle and ventricle, through which the blood paſſes in its courſe from the firſt tree of this ſyſtem to the ſecond, will be deſcribed in a future part of this article in the general account of the heart.

The firſt tree of the red blooded circulation, the trunk of the ſecond, and the heart which connects theſe together, are concentrated in the cavity of the cheſt; while the branches of the ſecond trunk are diſperſed through all the organs of the economy, and reach to all the extreme points of the body.

The organ of motion of the red blood, or the heart, is placed about the upper part of the middle third of the body. "This poſition," ſays Bichat, "is not a matter of indifference. It places more immediately under the influence of this viſcus, all the upper parts of the body, particularly the head, the organs of which, eſpecially the brain, require an habitual and powerful excitation from the blood, in order to maintain their functions in a ſtate of permanent activity. Hence, in the gangrene of old age, and in other affections arriſing from the blood being propelled with diminiſhed force to all parts of the body, the toes are firſt affected, and the hands are much ſeldomer and later attacked in this way. In general there are very numerous differences between the phenomena exhibited in the upper parts of the body, and thoſe which take place in the lower. In the integuments we find that portion of the general capillary ſyſtem, which belongs to the former, infinitely more ſuſceptible of diſtenſion with blood, than that of the latter; as is proved by aſphyxia, apoplexy, drowning, the various cutaneous affections, and even injections. Theſe differences may obviouſly be referred to the relative poſition of the upper and lower parts of the body to the heart."

Bichat finds fault with the accounts, which anatomical writers have generally given, of the origin of the aorta from the heart, and deſcribes it in the following way. "The internal lining of the left or aortic ventricle, after lining that cavity, enters the mouth of the aorta, is ſo folded as to form the three ſemilunar valves, and is there continued into the veſſels lining it and its branches. The artery is connected to the heart merely by the intervention of this membrane. The proper fibrous coat of the artery is not identified with the muſcular ſubſtance of the heart. Its extremity ends in three ſemi-circular feſtoons, correſponding to the three ſemi-circular valves which they ſupport. The feſtoons do not reach to the muſcular fibres of the ventricle, ſince there is between them an interval of two or three lines cloſed by the internal membrane only. There are three ſmall triangular ſpaces between the feſtoons and the valves, filled in the ſame manner by the membrane. In order to obſerve this ſtructure clearly, the origin of the aorta ſhould be diſſected from the outſide, and carefully cleaned from the ſurrounding adipous matter. Then, by ſlitting up the ventricle and the artery, after having removed the valve, and obſerving their union againſt the light, the ſtructure now deſcribed will become very apparent, in conſequence of the tranſparence of the internal membrane, and the opacity of the three portions, by which the aorta commences. Hence it follows, that if the veſſel be exactly diſſected on the outſide, and the internal membrane of the canal containing the red blood be detached from below upwards, the artery will be completely ſeparated from the heart. This marked diſtinction between the aortic fibres and thoſe of the heart would be already a ſtrong preſumption, that their nature is different, even if an abundance of other conſiderations did not eſtabliſh the point in the moſt incontrovertible manner." The ſtatement of the French writer on this point does not deſerve all that credit on the ground of originality, which he himſelf ſeems inclined to claim. Haller gives the following deſcription of the origin of the pulmonary artery, and adds, that that of the aorta is exactly ſimilar. "Cartilago cordis in circuli perfecti formam terminatur, et fibræ tranſverſæ cordis partim inter valvulas arterioſas per lineæ longitudinem producuntur, et aliquanto plus, partim in parietem arteriæ, quæ finum valvuloſum perficit, pariter ſurſum pergunt, fere perſefquilineam, et accurate tranſverſæ cum alba pariter membrana arteriæ connectuntur, cellulaſe brevis tela ope, ut nulla cordis fibra in arteriam continuetur." Elem. Phyſiol. lib. 4, ſect. 3, §. 8.

The leading circumſtances concerning the ramifications and ſtructure of the arteries are mentioned under ARTERY: but we have ſomething further to ſtate on theſe ſubjects in the preſent place.

Having ariſen in the way juſt deſcribed from the left ventricle of the heart, the aorta divides very ſpeedily into two portions; of which the aſcending paſſes upwards to the neck, head, and upper limbs, while the deſcending purſues its courſe to the cheſt, abdomen, and lower limbs. The firſt, quickly ſubdivided into four principal trunks, differs from the latter, which remains a ſingle trunk for a conſiderable length. Since the latter has to paſs through a much more extenſive courſe than the former, it preſerves more effectually, by this diſpoſition, the whole ſum of motion communicated to the blood by the heart. Nevertheleſs, in conſequence of the ſmaller diſtance of the parts from the heart, the impulſe produced by its action is more ſtrongly felt by the ſuperior than by the inferior organs, as we have already obſerved. At the upper part of the pelvis the aorta is divided into two ſecondary trunks; ſoon after the ſubdiviſions begin, under the name of branches, and are ſubſequently continued under the terms of ramifications, twigs, &c.

It is difficult to ſtate accurately and generally how often the arteries divide in their courſe from the heart to their termination in veins. The mathematical phyſicians ſeem to have erred in aſſigning much too large a number of diviſions. Keil ſtates that there are forty or fifty, and relies chiefly on this ſuppoſition for making good his theory concerning the great retardation of the blood's velocity in the ſmall veſſels. "Much," ſays Haller, "muſt be detracted from this calculation, if we diminiſh, as we certainly muſt, the number of diviſions ſtated by this author. I have ſometimes counted the diviſions of the branches in the membranes of the inteſtines accurately injected, beginning from the heart, and ending in the very minute ramifications, as far as the eye could follow them. I have hardly ever found twenty diviſions: nor could there be many, between thoſe which I took for the laſt, and the commencement of the veins, both becauſe the ſmalleſt viſible arteries are extremely ſhort, not exceeding a few lines in length, and becauſe I reckoned down to the very convexity of the inteſtine, which is at the greateſt diſtance from the commencement of the trunks." Elem. Phyſiol. t. 1. p. 77.

Where arteries divide, or a branch is given off from any trunk, a projection is obſerved on the inſide of the tube, formed by the internal coat of the artery, and correſponding in its ſituation to the angle formed by the ſeparation of the branch, and favouring the change in the courſe of the blood by breaking the column. The form and appearance of this projection vary according to the nature of the angle. If the angle be a right one the edge is circular, and equally manifeſt in the whole circumference. Where the angle is acute, there is a very ſharp projection, of a ſemi-circular form, between the branch and the continuation of the trunk; but there is hardly any projection obſervable between the trunk itſelf, before the origin of the branch, and the commencement of the latter, in which ſituation there is an obtuſe angle on the outſide. In proportion as the latter angle is more obtuſe, and conſequently in proportion as the other is more acute, the laſt-mentioned prominence is leſs obſervable: its form, like that of the other, is ſemi-circular, and the two make together an entire circle, which is placed obliquely. That part of this circle, which is formed by the ſecond projection, is the neareſt to the heart. When there is an acute angle between the trunk and the branch, and an obtuſe one between the branch and the continuation of the trunk, the arrangement is exactly the inverſe of that laſt deſcribed. An oblique circle is obſerved at the mouth of the artery, of which the moſt projecting half is the neareſt to the heart.

The origin of the arterial trunks is tolerably conſtant, but that of the branches is expoſed to ſuch variety, that we hardly meet with two ſubjects exactly ſimilar in this reſpect. This circumſtance correſponds to the common variations of form obſerved in the organs of the organic life. Neither does their diſtribution obey the law of ſymmetry. Even in the limbs, which correſpond to each other, there are varieties in the origin and courſe of the branches.

The arterial diviſions take place very near each other. The carotid and the iliac arteries are almoſt the only inſtances of arterial tubes paſſing for conſiderable diſtances without producing any branches. Ramifications of different ſizes do not come off ſucceſſively according to their magnitude; but the largeſt trunks may produce very ſmall twigs; thus the aorta gives origin to the bronchial and thymic arteries.

The name of trunks is given to the firſt diviſions of the two great portions of the aorta already mentioned: ſuch are the carotids in the neck, the ſubclavians in the axillæ, and the iliacs below. Theſe are generally lodged in large cellular interſtices, as the groin, axilla, the neck and ſides of the pelvis. As they divide they form branches, which are received into leſs conſiderable intervals, and are, therefore, more immediately expoſed to the influence of the ſurrounding organs. They are generally covered in ſuch a manner by the neighbouring parts as to be ſhielded in great meaſure from external injury. Some have ſuppoſed that the contraction of the muſcles accelerates the blood's motion in theſe tubes, and, on the other hand, the movements of the arterial trunks produce in the neighbouring organs, and even in the whole limb, a very ſenſible motion, a kind of agitation, which, in the opinion of Bichat, maintains the vital energy. This fact may be rendered viſible by a very ſimple experiment. When the elbow is reſted on a table, and a body of ſome length is held in the hand, its extremity is obſerved to vacillate, and the motion follows exactly the pulſations of the arteries. When a perſon ſits with his knees croſſed, the foot of the upper leg is raiſed by each projection of blood into the arteries of the limb, and then ſinks again. To the ſame cauſe may be referred the motion of the brain, and that of tumours ſituated over the trunks of large arteries.

The courſe of the arteries differs much from that of the veins. The trunks of the latter veſſels are under the ſkin, and the deep-ſeated branches are ſmaller: the cutaneous branches of the arteries are ſmall and ſhort; the larger trunks have a deep-ſeated, and conſequently more ſafe poſition. It cannot, therefore, be generally aſſerted that veins accompany the arteries, unleſs it be at the ſame time obſerved, that the deep-ſeated venous tubes, following the large arteries, are comparatively ſmall, and that the cutaneous arterial ramifications which accompany the large venous trunks, are ſtill ſmaller. The vertebral arteries run through the long canals of the tranſverſe proceſſes, while the veins lie on the outſide; the radial, ulnar, tibial, peroneal, and lingual arteries, have each a ſmall vein cloſe to them, while the large trunks of the cephalic, baſilic, ſaphenæ, and external jugular veins paſs ſuperficially without any attendant arterial ramifications. This arrangement leſſens the danger of hæmorrhage in wounds; the impulſe of the heart occaſions great riſk from the diviſion of an artery, while that of a vein is attended with little danger in compariſon. Where the courſe of the vein is in a protected ſituation, as when covered by bones or large muſcles, it

it is often attended by an artery; as in the meſentery, kidnies, lungs, arm and thigh.

The direction varies in the trunks and branches. The former are commonly ſtraight, and conſequently the circulation goes on in them almoſt inſenſibly; when they are laid bare in a living animal, no locomotion is obſervable. Yet ſome exceptions occur to this rule; as in the arch of the aorta, and the curvatures of the internal carotid. The branches are more tortuous, and this arrangement gives riſe to that motion of the veſſel, which, according to ſome, produces the pulſe.

The ſmaller diviſions of the arteries run in the interior of our organs, without, however, entering into their intimate ſtructure. Thus, in the muſcles, they paſs between the fibres, in the brain between the convolutions, in the glands between the lobes of which they conſiſt, &c. "By theſe," ſays Bichat, "an inteſtine motion is communicated to the whole organ, which facilitates its functions, and keeps up the activity of its various parts, as the more general motion already ſpoken of ſupports that of the whole part taken together. The ſudden ceſſation of life, when the blood ceaſes to agitate the brain, proves the immediate connection between this inteſtine motion and its active powers. Hence, we obſerve, that the vital energies are more decidedly marked in all parts where the arteries are very numerous, as in the muſcles, the ſkin, the mucous ſurfaces, &c.; while, on the contrary, the vital phenomena are much more obſcure in organs of leſs vaſcularity, as the tendons, cartilages, bone, and other white parts.

The tortuoſities of the arteries increaſe as they become more minutely divided, and injections render this point very clear, particularly in the brain; but as theſe turns depend very much on the cellular ſubſtance, they diſappear partly when the veſſel is inflated on all ſides. They are much increaſed when the veſſels are diſtended in injection. In the article CIRCULATION, we have conſidered how far the common opinion, which aſſigns this arrangement as the cauſe of retardation in the blood's motion is correct, and have expreſſed our doubts whether it is at all founded in truth. The remarks of Bichat coincide with this view of the ſubject. "Where the ſtomach or inteſtine is expoſed in a living animal, alternately in a ſtate of plenitude and emptineſs, I have found the circulation nearly equally rapid in both caſes; although in the firſt inſtance, the veſſels muſt have been rendered ſtraight by the diſtenſion, and in the ſecond, they muſt have been thrown into curves. I opened the carotid in a dog, and, after obſerving the jet of blood, expoſed both ſides of the cheſt. The lungs immediately collapſed, and their veſſels muſt have become folded on themſelves; yet the ſtream of blood proceeding from the wound, and which muſt have come through the pulmonary veſſels, was not retarded, and it was only gradually enfeebled by the action of other cauſes, which need not be particularized here. If, after opening an artery, the trachea be alſo opened, and all the air contained in the lungs ſuddenly extracted by means of a ſyringe adapted to the aperture, thoſe organs are reduced at once to a very ſmall bulk; their veſſels muſt, therefore, be at once conſiderably folded on themſelves; yet the blood continues to flow with equal force as before from the opened artery. Laſtly, after opening the abdomen of a living animal, I have alternately folded and ſtretched out the meſentery, of which ſeveral arteries had been previouſly opened; no difference was perceptible in the jet of blood in theſe two ſtates of the part. The ceſſation of the pulſation at the wriſt, when the arm is forcibly bent, does not ariſe from the angle formed in the artery in conſequence of that particular poſition of the limb, but from the direct preſſure of the ſurrounding parts on the arterial tube. The ſingle turn of the brachial artery in this caſe ſhould produce much leſs effect than the numerous windings of the internal carotid, which, however, do not ſeem to have any influence on the courſe of the blood. If the whole arterial ſyſtem were empty, and the blood departed from the heart to fill it ſucceſſively, the courſe of the fluid might be retarded by its ſtriking againſt the windings of the arteries. Hence, in anatomical injections, a tortuous artery is leſs readily filled: the ſpermatic, for example, is often not diſtended by the injected fluid. The caſe is very different in an aſſemblage of tubes completely full of fluid; the ſhock impreſſed at the commencement of this ſyſtem is propagated ſuddenly through all the cavities."

The windings in the courſe of the arteries allow theſe tubes to accommodate themſelves to the varying poſitions of the organs in which they run, without their undergoing any actual extenſion; hence, they are moſt remarkable in parts which exert a conſiderable motion in the execution of their functions, as in the lips and other parts of the face, the tongue, the uterus, the hollow viſcera, as the ſtomach and the inteſtines.

This opinion concerning the end obtained by the winding courſe of arteries, is more fully explained in the following quotation from Haller: "Facile vero finis fabricantis naturæ proſpicitur. Arteria flexa omnino multo longior eſt, ea recta linea, quæ per medias flexiones tranſit, et arteriæ longitudinem metitur, ſi ea recta foret; poteſt adeo arteria flexa, quoties ejus finis a principio removetur, abſque ullo incommodo longior reddi, dum gyri a ſe invicem recedunt, et arteria totam ſuam longitudinem explicat, quæ nunc exporrecta diſtantiam terminorum metitur. Eſt enim ea harum flexionum conſtans indoles, ut arteria circa lineam imaginabilem decurrat, ſupra quam alterne elevatur, infraque eandem viciſſim deprimitur. Plethora et injectiones anatomicæ has flexiones augent. Arteriæ cerebri, dum inanes ſunt, pene rectæ videntur: eædem repletæ flexuoſæ fiunt. Quæ vero arteriæ etiam inanes flexuoſæ ſunt, eædem repletæ ad angulos minores incurvantur, ſi interim ea pars corporis animalis, cui incumbunt, longitudinem ſuam non mutaverit." (Elem. Phyſiol. lib. 2. ſect. 1. § 20.)

The arterial anaſtomoſes are of two kinds: 1ſt, where two equal trunks unite together, and, 2dly, where a large branch is joined by a ſmaller. Three varieties may be obſerved in the firſt of theſe modes. 1ſt. The two arteries may be joined together at an acute angle, ſo as to form a ſingle trunk; this may be ſeen in the junction of the ductus arterioſus and aorta, and of the two vertebrals. 2dly. Two arteries may be joined by a tranſverſe branch, as, for example, the anteriores cerebri. 3dly. They may join ſo as to form an arch; the meſenteric veſſels afford examples of this arrangement. Here the branches are given off from the convexity of the arch. In the firſt caſe, two columns of blood are united into one, which takes the middle courſe between the directions of the former: in the ſecond, the two columns purſue their original courſe, and merely communicate together: in the laſt, they meet together, coming in oppoſite directions, and the blood goes on through ſecondary ramifications. The ſecond kind of anaſtomoſes, formed by the junction of conſiderable branches with ſmaller ones, is very frequent, and exhibits no varieties. Theſe communications, which grow more and more frequent, as the arteries become ſmaller, are at laſt ſo numerous and univerſal, that theſe veſſels form one general network over the whole body. "To this ſyſtem," ſays Scarpa, (on aneuriſms), "may be juſtly applied the ſaying of Hippocrates, in toto corpore unus conſenſus et una conſpiratio: for it may be

be boldly ſtated, that the whole body is an anaſtomoſis of veſſels, a vaſcular circle. This fact is ſo true, that although in ſome rare caſes there may occur a conſtriction and obliteration of the great artery of the body, (I mean the aorta), immediately below the arch, which this artery makes; the circulation through the reſt of the body, from the neck to the feet, is not thereby ſtopped or obſtructed." And he adds this further remarkable proof of the fact: "I have repeatedly had occaſion to obſerve, what others may likewiſe ſee at pleaſure, that on tying tightly the aorta in the dead ſubject, immediately below its arch, in order to throw with great force the injection into the arterial veſſels of the head and arms, a very fluid injection has likewiſe found its way, by the veſſels of the neck, by the ſubclavian, the dorſal, and eſpecially the two upper intercoſtal arteries, into the arteries of the thorax, and to thoſe of the abdomen, and for a long ſpace, even to the principal arterial trunks of the lower extremities." P. 48. This fact, of the freedom and univerſality of the arterial anaſtomoſes, is highly important in ſurgery, as it enables us to tie any of the large arterial trunks, in the caſes of aneuriſm, without any apprehenſion for the ſubſequent nouriſhment of the limb.

Many phyſiologiſts have repreſented the arteries as conical;—have conſidered each artery as a cone, of which the baſis is at the heart, and the apex at the extremities of the body.

In this view of the ſubject the following ſuppoſition is made; *viz.* that you ſhould ſelect any artery, as that of the finger for example, follow it to its trunk, and ſucceſſively trace the canal to the aorta and the heart; in which caſe it will be found, that the area increaſes conſtantly as you approach the heart. Hence, an artery may be called conical, when the aorta is followed out to the end of any particular branch on the ſurface of the body; and we may conceive in our imagination this continuation of the tube to the finger as a ſingle canal, of which the origin and baſis are in the heart, the termination and apex in the finger. But there are ſeveral circumſtances to be taken into the account in this caſe. The decreaſe in the ſize of the veſſel ſeems to depend leſs on its diſtance from the heart, than on the branches which it furniſhes in its courſe. When an artery runs for ſome length, without giving off any branch, or at leaſt any important one, from its ſize, it does not ſeem to be diminiſhed in that ſpace, if common modes of meaſurement can be truſted. Ræderer obſerved the umbilical artery to be larger in the chord than at the opening in the linea alba. The trunk of the carotid is not ſmaller at its diviſion than at its origin; neither is the vertebral artery diminiſhed in the neighbourhood of the occiput, although it has ſent branches off in its courſe through the tranſverſe proceſſes of the cervical vertebræ. Senac has aſcertained the ſame fact concerning the thoracic aorta, the humeral, radial, and internal mammary arteries. This is the reſult obtained by examining the tube of an artery between two branches, by ſlitting it up when empty, or meaſuring it when full of blood. Hence we are led to conſider an artery, which has been generally termed conical, as compoſed of a ſeries of cylinders, ſucceſſively decreaſing, adapted to each other in ſuch a manner, that, at the origin of any tolerably large branches, two of them meet together, the larger being between the heart and the origin of the branch, the inferior beyond the origin.

Mr. Hunter affirms, that an artery which produces no branches, actually increaſes in ſize as it proceeds from the heart. "The arteries of the placenta evidently increaſe in ſize, the nearer they approach to the placenta; and this ſo very conſiderably, as to require no experiment, unleſs it be intended to aſcertain the difference correctly. In the ſpermatic artery of the bull it is equally evident: but as theſe arteries are much longer than the diſtance between their origin and the parts which they are to ſupply, it may be ſuppoſed that this increaſe is peculiar to them, in order to anſwer ſome particular purpoſe; but the carotid arteries, in ſome animals, afford ſufficient proof that the arteries in common become larger as they paſs on and ramify; for the carotids may be reckoned ramifying arteries, as they ſend off branches.' (On the Blood, p. 169.) Mr. Hunter then relates the reſult of ſome trials on the carotid artery of the camel and the ſwan. On weighing exactly equal ſections from the upper and lower end of the carotid of a camel, he found that the former was one grain and a half heavier than the latter. "The carotid artery of another camel, meaſuring three feet and a half in length, was found to ſend off forty-four ſmall branches, about the ſize of the human intercoſtal-arteries, with one as large as the ulnar. Of this artery, a tranſverſe ſection, of one inch in length, being taken from each end, and weighed; that from the lower end was found to weigh two ſcruples, 16 grains and a half: while that from the upper end weighed only two ſcruples, fourteen grains and a half. In ſimilar ſections of the oppoſite carotid, which ſent off forty-ſeven branches, the difference in weight between the upper and lower ſection was five grains. Similar ſections from carotid arteries of a ſwan being weighed, the lower ſections were found to be three grains and a half heavier than the upper; the lower ſection weighing thirteen grains and a half. Had the lateral branches been preſerved an inch long, being the length of the ſections of the trunk, I believe each might have weighed above a grain, and in that caſe, the forty-four would have been nearly equal in weight to the trunk; ſhould this be true, the arteries increaſe very conſiderably, not only in their ramifications, but in their trunks. I imagine, if the carotid artery in the camel did not ſend off any branch in its courſe, it would increaſe in ſize nearly in the ſame proportion with the umbilical artery, or the ſpermatic in the bull.

"It is to be obſerved, that as arteries divide, they increaſe in ſize much faſter than if they did not; for inſtance, if a ſection of an artery, two inches long, is equally divided into two, the ſection that is the further from the heart ſhall be heavier than the other, perhaps by one grain; but if the moſt diſtant ſection had divided into two branches, the two taken together would have been a grain and a half heavier; if three branches, two grains heavier, &c." Ibid. p. 170. On this ſubject the reader may refer alſo to Haller, Element. Phyſiolog. t. i. p. 56 et ſeq.

We have already obſerved, that the arterial ſyſtem, taken altogether, repreſents a cone, whoſe baſe is in all parts of the body, and its apex at the heart; that is, that the diameter of the aorta is leſs conſiderable than that of all its branches united. This is proved by comparing a trunk with the two branches formed from it; the latter ſurpaſs it in diameter, and as the proportion is conſtantly the ſame in all the ſub-diviſions, it muſt be obvious that the capacity of the arterial ſyſtem is conſtantly increaſing. The amount of this augmentation has been variouſly ſtated, and the reports of the various authors who have conſidered the ſubject, are collected by Haller in the firſt ſection of the ſecond book of his Element. Phyſiol. § 18. Senac found the proportion of the aorta to its branches to be as 81 to 144; of the axillary 484 to 1296; of the brachial to the radial and ulnar 36 to 64; of the aorta above the origin of the cæliac, to the ſame veſſel below that point, together with the cæliac, 1764, to 3249. Haller himſelf gives the following numbers as the proportions between the trunk of the aorta on one ſide, and on the other, the

the three branches arifing from its arch and the trunk after their origin, as obferved in different trials: 4900 to 6075; 3789 to 4659; and 1521 to 2250. He found the proportion of the trunk of the fuperior mefenteric to its eleven branches to be as 529 to 988: and of the carotid to its external and internal branches as 529 to 768.

Although there can be no doubt that the capacity of the arterial fyftem increafes as it proceeds from the heart, the general opinions concerning the mode and degree of this augmentation, and the ratio of the branches to the trunk in each particular inftance, have been called in queftion by fome phyfiologifts. "It has been commonly taught, "fays Blumenbach," that in the whole arterial fyftem, the branches are more capacious than the trunk from which they arife. I apprehend that this propofition has been enunciated too generally, and that the meafure of the *diameter* has been often very improperly confounded with that of the *area* of the veffel. I have examined this point more than once, not in veffels diftended with injection, but in the undifturbed arteries of the moft recent fubjects, and have found, in the cafe of the innominata and its right carotid and fubclavian branches, and of the brachial with its radial and ulnar divifions, that the areas of the branches did not at all exceed that of the trunk in capacity." (Inftit. Phyfiol. fect. 7, § 90.) Bichat mentions another fource of error on this fubject; "that of meafuring the arteries on their exterior after injecting them: in fact, the calibre of trunks is greater, in proportion to the thicknefs of their fides, than that of the branches taken feparately: in other words, the parietes of the aorta are lefs thick, ceteris paribus, in proportion to its cavity than thofe of the ulnar artery. To this circumftance we may undoubtedly refer the comparatively rare occurrence of aneurifms in the branches, and their frequency in the trunks." Anat. Gener. t. ii. p. 275

After having been divided and fubdivided, and having exhibited in their courfe the appearances juft detailed, the arteries end in the general capillary fyftem. It is almoft impoffible to fhew where the latter commences and the arteries end: we may, indeed, ftate, that it is at the point where the blood ceafes to be entirely under the influence of the heart, and has its motion kept up by the infenfible contractility of the vafcular parietes: but the line of demarcation cannot be rendered obvious to the fenfes.

In treating of the termination of the arteries, authors have confidered their continuity with the excretory tubes, exhalants, veins, &c.; but the general capillary fyftem is clearly interpofed between the latter kind of veffels and the arteries. We fhall therefore refer what we have to fay of their origins to our account of the capillary fyftem, which is difperfed through all the organs of the body, but prefents effential differences, in refpect to its continuity with the arteries, according to the different fyftems in which it is found. There are fyftems in which the above-mentioned tubes are found in great numbers, and where, confequently, the general capillary fyftem contains much blood; fuch are the glandular, the mucous, the cutaneous, the mufcular, &c. Other fyftems receive but few arteries, as the offeous, fibrous, ferous, &c.; and have therefore but a fmall quantity of blood circulating through their capillaries. Laftly, the cartilaginous, hairy, and cuticular fyftems poffefs no arteries, and contain only colourlefs fluids in their capillary veffels.

The arteries are compofed of fucceffive membranous ftrata, differing in their organization and appearance. The firft of thefe is called the *cellular* or *external* coat, and forms the medium of connection between the veffel and the furrounding parts. Within the cavity of the pericardium, the origin of the aorta is covered by the reflected portion of that membrane, a certain quantity of cellular and adipous fubftance being interpofed. On the left fide of the cheft, and in fome parts of the abdomen, this artery and its iliac branches are covered in a fimilar manner by the peritoneum on their anterior furface. Thefe coverings are foreign to the effential conftruction of the artery, and are adventitious circumftances arifing from local caufes. With the exception of the arteries in the head and thofe of the navel ftring, thefe veffels are connected on all fides to the furrounding parts by cellular fubftance. This covering, which is very conftant, envelopes the whole artery and all its branches on all fides, connecting them to the neighbouring vifcera, membranes, periofteum, and mufcles. The threads compofing it are fhort, and more delicate in proportion as the arterial divifions are more minute; but it is never abfent, fince the fmalleft perceptible veffels are ftill connected by cellular threads, and become loofe and moveable when thefe are removed. In the larger trunks this covering is more loofe, compofed of longer threads, united at very acute angles, and nearly parallel, free from fat, and fometimes called the *cellular fheath* of the artery. Nerves and fmall blood-veffels are frequently difperfed in thefe fheaths, fo as to give them a peculiar reddifh appearance. A remarkable example of this ftructure may be feen in the carotid artery. Where thefe veffels are tortuous, their turnings are deftroyed by removing the cellular fubftance, and they then appear ftraight. In the neighbourhood of the artery this covering feldom contains any fat, but that fubftance is obferved in the cells, as we approach the furrounding parts. When the veffel is divided, its cut ends are withdrawn within this fheath, in confequence of the power of retraction, which is then exerted. This cellular fheath gives a pulpy flocculent appearance to the outfides of the artery, more particularly if it has been inflated, or if its cells have been diftended by maceration in water; hence the term of *villous* coat, as applied to the covering in queftion.

Immediately round the artery the cellular fubftance forms a very denfe, clofe, and firm layer, which on the firft view appears to be a peculiar membrane, but, on more accurate examination, is found to belong to the cellular fyftem. Yet this is never the feat of ferous effufion in anafarca, nor does it ever contain fat. It is formed by the gradual condenfation of the furrounding cellular fubftance, which affumes a more and more compact texture, and the threads of which are at laft fo firmly interwoven, that it may be detached in a continuous ftratum, forming a kind of canal, correfponding to that of the artery, which it contains and fupports. After confiderable maceration, the cells of this part are fo diftended with water that it feems to conift entirely of a fpongy cellular fubftance. According as different authors have attended more particularly to the furrounding cellular fheath, which connects the artery to the neighbouring parts, or to the condenfed layer, which immediately inveits the canal, their defcriptions have varied in fome particulars. Haller's account is very correct, and he diftinguifhes the two portions by different names, calling the latter the tunica cellulofa propria, and the former cellulofa adfcititia. This cellular organ, taken altogether, feems rather fubfervient to the office of connecting the veffel in its fituation, than effentially concerned in the execution of its functions; hence it is not included by fome in their enumeration of the arterial coats. Walter in the Memoires de Berlin, 1785, defcribes only two coverings of the arterial tubes; and Scarpa, in his large work on aneurifm, calls the two ftrata, which we fhall prefently defcribe, the *proper coats* of the artery.

The moft ftriking characteriftic of the arteries is their fecond covering, called by fome anatomifts fimply tunica

media,

media, by others the muſcular or fibrous coat, and by Bichat, la membrane propre. It is a denſe and firm covering, very apparent on the large arteries, and leſs ſenſible on the ſmaller ramifications, on which it is gradually loſt. Its colour is uniform throughout: the apparent redneſs of the branches, and yellowneſs of the trunks in living animals, depend merely on the tranſparency of the former allowing the blood to be diſcerned through their ſides, and the opacity of the latter. The colour of the arterial fibre is yellowiſh; yet it aſſumes, under certain circumſtances, a ſomewhat grey hue. Often, after a few days maceration, it grows red, or rather roſe coloured, like the cartilages of the fœtus, or the fibro-cartilages of the adult when ſimilarly treated. The external or cellular covering always becomes whiter from maceration. The redneſs produced in the arterial fibre by immerſion in water diſappears in conſequence of continued maceration. "The thickneſs of the proper arterial membrane," ſays Bichat, "is conſiderable in the large trunks. It decreaſes gradually; and this circumſtance diſtinguiſhes it from the internal coat, which I have found nearly as thick in the tibial artery as in the aorta. The arteries of the brain have been ſaid entirely to want the fibrous coat. Undoubtedly this covering is thinner in proportion on the trunks of the internal carotid and vertebral, than in arteries of equal magnitude, which run in the muſcular interſtices of the body; but an attentive examination of theſe veſſels has enabled me to diſtinguiſh clearly circular fibres. Can we explain the extravaſations of blood, which are ſo frequent in the brain, from the thinneſs of the arterial ſides? This is a matter of doubt. Such effuſions take place only from the capillaries; the trunks are never concerned; and hence I have ſought in vain to diſcover the torn veſſels by injections." The organization and arrangement of this covering ſeem to be uniform in all other parts of the body; perhaps it may be thinner in the interior of the viſcera, as the liver, ſpleen, &c. than in the intervals of the muſcles.

This fibrous coat is compoſed of very diſtinct fibres, adhering to each other, but ſeparable without much force, diſpoſed in ſucceſſive concentric ſtrata, ſo that, after removing the cellular covering, the various layers may be detached without trouble, which circumſtance has led ſeveral authors to repreſent the large arteries as being formed of ſeveral coats. The fibres are circular, or nearly ſo; and the exterior ones have ſome attachment to the cloſe cellular tiſſue which is contiguous to them. Hence, when we remove the latter, a greater or leſs number of the fibres remains connected to it. The internal membrane may be eaſily ſeparated, without carrying away any of the arterial fibres.

Haller's deſcription of this part repreſents it as more decidedly of a muſcular nature. "Poſt hanc præcipuam arteriæ partem ſequuntur interiores *carneæ fibræ*, quas in arteriæ aortæ principio inprimis contemplatus ſum, qua in ſede utique et copia et rubore facilius ſe produnt. Multorum ibi ſtratorum ſunt, quorum alia poſt alia eleves, denſæ, celluloſitate pauciſſima ſeparatæ, duræ, in circulum flexæ. Eam vocem ita volo ſumtam, ut nulla quidem fibra integrum circulum abſolvat, annuloque poſſit comparari. Perinde enim, ut in aliis muſculis, rectæ breveſque fibræ extremos fines ſuos ad latus detortos inter vicina ſui ſimilia carnea ſila abſcondunt. Hæc eſt *muſculoſa* tunica arteriarum, a pleriſque anatomicis recepta, quam primam arteriæ membranam vocavit Cl. Monrous. In minoribus arteriis ſenſim malignius apparet, in capillaribus denique ne lente quidem vitrea adhibita, qua rerum ſpecies augetur. A cerebri enim vaſis vulgo carneas fibras abeſſe ſcriptum eſt; quem errorem ita redarguit Cl. Ludwigius, ut tamen pauciores faciat." Elem. Phyſiol. lib. 2, ſect. 1, § 7. On another occaſion he ſpeaks more decidedly of the *muſcular* nature of theſe fibres; "in arteriis majoribus muſculoſam carnem deſcripſi, nihilque ab ipſis abeſſe volui, quo muſculi pollent." Oper. Minor. t. 1. p. 190.

Mr. Hunter, who conceived that the arteries poſſeſs a power of contracting like muſcles, does not deſcribe the fibrous coat as compoſed of muſcular fibres; nor indeed does he ſpeak very clearly on the ſubject. He rather infers the exiſtence of muſcular fibres, from his notion that arteries certainly exhibit phenomena, which can only be accounted for by aſſigning to them muſcular ſtructure. "Although, when we conſider the conſtruction and uſe of the arteries, we muſt at once ſee the neceſſity of their having theſe two powers (the muſcular and elaſtic); yet, in the greateſt number, it is impoſſible to give clear ocular demonſtration of the exiſtence of diſtinct muſcular fibres. But ſtill, as arteries are evidently compoſed of two diſtinct ſubſtances, one of which is demonſtrably elaſtic, and we *know them likewiſe to be endowed with the power of contraction, peculiar to a muſcle*, it is reaſonable to ſuppoſe the other ſubſtance to be muſcular; I ſhall endeavour alſo to prove its exiſtence in ſuch veſſels, from their having the power of contraction in the action of death." On the Blood, p. 117.

In the ſubſequent paſſages, he attempts to ſhew how the muſcular part may be diſtinguiſhed by the eye. By looking on the cut edge of an artery, he ſays, we ſhall obſerve, that it is redder towards the inner ſurface; that this darker coloured portion begins almoſt inſenſibly in the larger arteries, and increaſes in amount as the veſſels become ſmaller. He ſtates further, that the difference in ſtructure between theſe parts is not very conſiderable, and that the elaſtic and muſcular fibres are intermixed. The account on the whole is by no means clear; and the aſſertion of a difference between the outer and inner portions of the fibrous coat is not founded in fact; while the notion of two different tiſſues being intermixed, as he conſiders the muſcular and elaſtic to be, is repugnant to our obſervations on all other parts of the animal machine.

When a branch ariſes from any trunk, the circular fibres of the latter are ſeparated, and form on each ſide a half circle, from the union of which an entire circle is formed, ſurrounding and embracing the ſmall rings formed by the circular fibres of the branch. The latter are continued to the internal prominence of the lining membrane, which is ſeen on the inſide of the arterial cavity, as we have already deſcribed. Theſe projections are in fact made by the fibrous coat covered on its inner ſurface by the internal membrane. There is, however, very little continuity between the fibres of the trunk and thoſe of the branch; they are chiefly connected together by the continuity of the cellular and the internal coats. When two equal branches ariſe from a trunk, as the iliac arteries from the aorta, the laſt circular fibres of the primitive trunk are intimately united with the commencement of each of the two circular planes, which ariſe at the level of the ſemi-circular projection, ſeparating the two arteries internally.

There are no longitudinal fibres, nor indeed any but the circular already deſcribed, in the arterial ſyſtem.

"What," ſays Bichat, "is the nature of the arterial fibre? Moſt anatomiſts have conſidered it as identical with the muſcular; yet a very curſory examination will ſuffice to convince us of their differences. It is not the abſence of the red colour that eſtabliſhes this difference, ſince, in the human body, many parts, undoubtedly muſcular, as the inteſtines, do not poſſeſs it. But the muſcular tiſſue is ſoft, looſe, and eaſily ſtretched; while the arterial fibres are firm and ſolid, and break rather than give way to the ſtretching. The

conſequences

conſequences of this difference are eaſily ſeen in the effects of a ligature. When an artery is tied firmly, the two internal coats are divided, and the cellular covering alone ſuſtains the effect of the ligature, which however is immediately applied to it. On expoſing the tube, a ſection, preciſely like what would be produced by a cutting inſtrument, is ſeen correſponding to the ſituation of the thread. The reſult of this experiment, which I have often repeated, is conſtantly the ſame; and I conſider the arterial tiſſue to be the moſt brittle of any in the body; a ſimilar experiment performed on an inteſtine, where the fibres, as in an artery, are circular, produces different effects; they are compreſſed and bruiſed, but not cut through. Arteries differ from muſcles in almoſt every point; in their organic and vital properties, in their developement and diſeaſes." The power of reſiſtance of the arteries in their natural ſtate is very conſiderable, although the fibres ſeem to give way eaſily in aneuriſms, and under the application of ligatures; and this ſtrength is exerted both in the tranſverſe and longitudinal directions. A conſiderable force is neceſſary to burſt an arterial trunk, by the injection of air or any other fluid; ſo great a force, that the effect can hardly be produced ſuddenly by the heart's action, and aneuriſms muſt be formed by a progreſſive and continued action on the arterial parietes, of which the tiſſue is probably previouſly diſeaſed. Wintringham, who inveſtigated this ſubject by means of injections of air, found that the aorta was burſt in a young ſubject, near the heart, by a force equal to 119 lb. 5 oz; and further down by 131 lb. 10 oz. The carotid of a ſmall dog was burſt by 25 $\frac{7}{10}$ lb.; the ſplenic artery of a man by 41 lb. 8 oz.; and its ſtrength, compared to that of the aorta, was as 1319 to 1000; that of the renal artery to the aorta, as 51 to 40. If an artery and a muſcle be extended longitudinally in the dead ſubject, the former is the moſt difficultly torn; but the reſult of a ſimilar trial in the living ſubject is juſt the reverſe; the artery will yield to a pretty ſtrong extenſion, which muſt be vaſtly augmented in order to tear the muſcle. The ſource of this difference muſt manifeſtly be ſought in the vital properties of the latter; it contracts violently under the circumſtances juſt ſtated, while the artery reſiſts only by means of its organic properties.

This power of reſiſtance in the arterial parietes is neceſſary to enable them to withſtand the action of the heart, more particularly when the contractility of that organ is unuſually exerted: in this point of view, a relation muſt always ſubſiſt between the power of the heart, and the ſtrength of the large arteries.

The fibrous covering of the arteries is a diſtinct and peculiar tiſſue of the animal economy: its fibres alone could have led to the notion of its being muſcular; but this property is common to it with ligaments and tendons, and external forms cannot regulate the intimate nature of organs. The action of the various re-agents on the arteries ſhews another claſs of ſtriking differences between their fibres and thoſe of muſcles. "When dried in the air they aſſume a reddiſh yellow colour, dark and approaching to black in the large trunks, more clear in the ſmaller ones. In this ſtate the arterial tiſſue is hard and extremely brittle, and breaks with a cracking, which is not obſerved in any other animal ſtructure. In this mode of preparation, the difference between the cellular covering and the fibrous ſubſtance is clearly obſerved, the former remaining flexible. The latter loſes very little of its thickneſs in drying; and this circumſtance diſtinguiſhes it from moſt other tiſſues. It ariſes from the ſmall quantity of fluid contained between its laminæ, a circumſtance, which ſeems to depend on the abſence of cellular ſubſtance in this ſituation. We cannot fail to be ſtruck with the dryneſs of the arterial laminæ, as contraſted with the humidity of muſcular fibres. When expoſed in this ſituation, among the ſurrounding parts, to the action of air, the arteries putrefy ſlowly; indeed for a certain time they ſeem almoſt to reſiſt this change. They give a much leſs fœtid odour than other tiſſues, when allowed to putrefy ſeparately, and produce a ſmaller proportion of ammoniacal matters. The want of fetidity characteriſes the water, in which arteries, completely ſeparated from all ſurrounding ſubſtances, have been macerated; and the difference is very ſtriking, when this water is compared to that in which muſcles have been macerated; we find alſo, that the arteries are almoſt unaffected when the viſcera, in which they run, as the liver, ſpleen, &c. are reduced into a ſoft maſs of putrefaction. In the living ſtate alſo, theſe veſſels reſiſt diſeaſe much longer than the other ſoft parts: hence the arteries are often ſeen as it were diſſected and inſulated, when ſloughing has carried away the ſurrounding ſubſtance. In the end, however, maceration or expoſure to air deſtroys the texture of the arteries; and the effect is produced much the moſt rapidly by the latter method. In the former caſe the part is gradually ſoftened, and after loſing the coheſion of its fibres, is reſolved into an homogeneous and greyiſh pulp. Expoſure to air renders the veſſel at firſt of a greyiſh colour, and afterwards reduces it to a pulp.

Expoſure to heat produces criſpation, or contraction and curling of the veſſel to the greateſt degree. Boiling has the following effect: 1ſt. Very little ſcum ariſes before ebullition, which is juſt the contrary of what we ſee in the muſcular ſyſtem, under ſimilar circumſtances. 2dly. There is a very marked criſpation at the moment of ebullition; but exerted more ſenſibly in the direction of the diameter, than in the axis of the veſſel; the artery at the ſame time becomes harder, and the water gains a yelloviſh tint. 3dly. The part is again ſoftened; but a greyiſh tint ſucceeds to the yellow colour; the fibres loſe their coheſion, ſo as to break with great facility. 4thly. However the ebullition may be protracted, the arterial tiſſue is never reduced into a gelatinous and yellowiſh pulp, like the fibrous, cartilaginous, and others. The fibres remain in their original ſtate, with the ſame bulk and relations; having merely loſt their coherence, and changed their colour. 5thly. The broth produced is inſipid. Concentrated acids firſt corrugate, then ſoften, and afterwards reduce the arteries into a fluid ſtate, or rather into a pulp, which is yellow when the nitric, and black when the ſulphuric is employed. Other acids have a leſs ſenſible effect. In the diluted ſtate, there is no immediate corrugation, as the conſequence of immerſion: but the tiſſue is gradually ſoftened and becomes brittle, as after boiling. Alkalis, even in the cauſtic ſtate, have very little effect on the arteries.

Common Membrane of the circulating Syſtem of red Blood.—This lines the pulmonary veins, the left cavities of the heart, and the arteries: in the latter veſſels it is called ſimply the *internal* membrane, and has alſo been deſcribed by the names of villous, nervous, or cuticular. In order to inſulate this membranous lining in the arteries, the fibrous ſtrata ſhould be ſucceſſively removed: the laſt of theſe adheres but ſlightly to the membrane, which may eaſily be detached in the form of a canal for a conſiderable extent. It is diſtinguiſhed from the fibrous coat, by its extreme thinneſs and conſequent tranſparency: by its white colour, for the yellowneſs of the internal ſurface of the artery, previous to diſſection, ariſes from the fibrous coat; and by the entire abſence of fibres. Its inner ſurface is perfectly ſmooth, and its texture uniform, like that of ſerous membranes. But it is diſtin-

guiſhed from theſe membranes by the kind of brittleneſs which it poſſeſſes: it is torn by very ſlight force.

Although this membrane is continuous over the whole internal ſurface of the circulating ſyſtem of red blood, it preſents ſome differences of ſtructure in the different regions. It is thinner in the left ventricle, than in the correſponding auricle, and in the arteries. It is ſuſceptible in that ventricle, and in the pulmonary veins, of much more conſiderable dilatation than in the arteries, where it and the proper fibrous coat would inevitably be burſt by any conſiderable dilatation. On the inner ſurface of the auricle and on the mitral valves it aſſumes a peculiar whiteneſs, in conſequence of maceration. Air, water, heat, &c. act on this as on the fibrous coat of the artery. The ſmooth poliſhed ſurface of this membrane offers no obſtacle to the tranſmiſſion of the blood through the tubes which it lines; and the moiſture of the part after death ariſes probably from ſome adhering portion of ſcum, and not from any mucous fluid, different from the blood, ſecreted by the veſſels of the part. Folds of this membrane form the aortic and the mitral valves, and the angular projections at the various diviſions of the arteries. On the outſide, where it is but weakly connected to the fibrous coat, there is no cellular ſubſtance intervening between them: yet neither boiling, maceration, nor putrefaction produces its detachment without the aſſiſtance of diſſection.

Although the appearances of the two be very different, this membrane is very analogous in its properties to the former. Neither can be well arranged under any of the organic ſyſtems of the body: they ſeem to form ſeparate tiſſues marked by excluſive and diſtinct characters. The internal membrane when dried is more pliant than the fibrous coat, and remains tranſparent inſtead of aſſuming the deep tint of the other. The phenomena produced by the other reagents, except the corrugation, are nearly the ſame.

"Among all the organic ſyſtems," ſays Bichat, "this membrane is remarkable for its ſingular tendency to become oſſified in the old ſubject. This change will be found in ſeven out of every ten individuals after the 60th year of their age. The incruſtations conſtantly begin on the external ſurface of the inner coat, ſo that a thin pellicle ſeparates them from the blood. They do not obſerve the laws of common oſſification, as they do not exiſt previouſly in the ſtate of cartilage. The earthy matter is always depoſited in ſeparate plates of greater or leſs breadth: very ſeldom does the whole artery form a continuous ſolid tube. Membranous portions connect together the ſeparate plates, and allow the veſſel to accommodate itſelf to the motions neceſſary in the circulation. So long as the plates continue thin, the ſurface of the veſſel remains ſmooth, as in the natural ſtate; but if the depoſition be increaſed in quantity, they become thicker and project internally. The thin pellicle which covers them, and is continued over the neighbouring ſurface, gives way at their circumference, and they then adhere to the fibrous coat, only by their external ſurface. When they are numerous, and have paſſed into this ſtate, the whole lining of the arterial tube preſents numerous aſperities. Theſe circumſtances may be obſerved particularly in the origin and courſe of the aorta. All parts of the arterial ſyſtem are ſubject to this kind of oſſification, the branches ſeem to be affected as frequently as the trunks: the radial artery, for example, is often oſſified in old ſubjects. Such incruſtations, however, occur leſs frequently in the ſmaller twigs, and never in the capillaries.

"Similar bony depoſitions are ſeen in this membrane, where it forms the aortic and mitral valves; but they are hardly ever ſeen in the other parts of its expanſion over the interior of the left cavities of the heart. Oſſification of the trunk of the aorta is found by morbid reſearches to derange the circulation; but that of the ſmaller arterial trunks and branches does not impair this function in the ſlighteſt degree.

"The bony depoſitions, which we have juſt deſcribed, differ from thoſe, which come on in other parts of the body, inaſmuch as they are natural phenomena, while the others are accidental, and often preceded by inflammation, or other diſorders of the part. Conſequently the latter are not influenced by age, but happen in young ſubjects and adults, as well as in old perſons. Oſſifications of the internal arterial membrane may alſo occur before old age, but they are the moſt frequent, beyond all compariſon, at that time."

Of the common Parts belonging to the Organiſation of the circulating Syſtem of red Blood.—The membranes, which compoſe the arterial tubes, are ſupplied with blood by ſmall arterial ramifications, called the vaſa arteriarum, and which ſerve the ſame purpoſes here, as in other ſtructures of the body. They come from the ramifications of the ſurrounding parts, and not from the trunk itſelf: for, if a portion of the common carotid be filled with fine injection, the arteries of its coats are not injected. The arteriolæ arteriarum firſt ramify in the cellular ſheath of the veſſel, where they divide and communicate in various ways, and ſend branches into the proper membrane of the artery, which are diſtributed among its laminæ, and terminate ſhort of the internal lining. "I have never ſeen," ſays Bichat, "any arteries penetrating to this coat, either after injection, nor in the living animal, after opening an artery, in which the courſe of the blood had been intercepted for a certain ſpace by the application of two ligatures. In order to diſtinguiſh the arterial veſſels clearly without injection, we ſhould ſelect a large trunk, as the aorta, in a young animal which has died of aſphyxia: all the ſmall arteries are then completely filled with black blood. In the fœtus, particularly if it died from aſphyxia in the birth, an abundance of blood-veſſels will be ſeen in the large arteries, which are rendered almoſt livid from this circumſtance." There is nothing particular to be obſerved concerning the veins, which muſt neceſſarily accompany the arteries now deſcribed.

The arteries are ſurrounded by two kinds of cellular tiſſue: one, which is quite external, and foreign to the arterial tube, is looſe, contains fat and ſerous fluid, and is compoſed of diſtinct laminæ, unites them to the ſurrounding organs, favours their motions, and forms a part of the general cellular ſyſtem: the other, which is compact, contains no fat, and is not laminated, forms the firſt of the arterial coats. This ſubſtance, and particularly the latter kind, maintains the folds of the arteries, which accordingly diſappear after diſſection, except in caſes where the veſſel is permanently held in the bent ſtate.

The cellular tiſſure does not ſeem to be continued into the interſtices of the fibrous coat of the artery, and this circumſtance particularly diſtinguiſhes the latter from the muſcular and other ſtructures. Long maceration exhibits nothing cellular in this part, and, when the artery yields at laſt to its continuance, it forms a mere pulp without any appearance of celluloſity. By detaching the fibres from each other, in careful diſſection, they ſeem to be held together merely by prolongations of the ſame nature with themſelves. Neither do we ſee any cellular ſubſtance between the fibrous and internal coats. "I conceive," ſays Bichat, "that this peculiarity contributes much to the peculiar brittleneſs, which characterizes the arterial tiſſue, and which occaſions it to give way under the application of a ligature. And on the ſame principle I ſhould explain the difficulty or rather the impoſſibility of arterial

arterial dilatations, or of the formation of cyſts by the arterial coats. There are no true aneuriſms; at leaſt, when the tumours are large; for the internal coats give way, and the cellular tunic alone is dilated." From the preceding views of the ſtructure of the arterial ſyſtem, the ſame author explains why there is never any fat in the coats of theſe veſſels; why they are never the ſeat of anaſarcous infiltration; why hydatids or cyſts are never developed between their laminæ; and why the various tumours, to which the cellular tiſſue gives birth; are never ſeen in thoſe organs. Granulations are never formed by its ſides after a wound; yet they are produced by the cellular covering of an artery laid bare, but not if that has been carefully diſſected away.

The proceſs of nutrition ſuppoſes the exiſtence of exhalants in the arteries; but there is no reaſon to believe that they open on the interior ſurface of theſe veſſels.

Bichat conceived that the empty ſtate of the arteries after death aroſe from the abſorbents continuing to act longer than the other parts, and made experiments to elucidate the ſubject. He incloſed blood and other fluids between two ligatures placed on the common carotid; but did not diſcover any diminution of them. Abſorbents generally abound where there is cellular tiſſue, and are not obſerved where this ſyſtem does not exiſt. Hence we ſhould not expect them in the arteries.

The firſt portion of the red-blooded circulating ſyſtem, (the pulmonary veins,) receives almoſt excluſively cerebral nerves, derived from the par vagum. The centre of the ſyſtem, or the heart, has branches from the ganglia as well as from cerebral nerves; and indeed more from the former than from the latter. The arterial ſyſtem is ſupplied almoſt excluſively from the ganglia, and the particular mode will be more minutely conſidered under the article NERVE. The cerebral nerves which often accompany the arteries in their courſe, very ſeldom give them any filaments.

Properties of the circulating Syſtem of red Blood.—We ſhall conſider in this place, thoſe properties only which belong to the arteries; thoſe of the veins and heart will be examined ſubſequently. Elaſticity, which is obſcure in moſt other animal tiſſues, characterized generally by conſiderable ſoftneſs, is very remarkable in the arteries; and this property particularly diſtinguiſhes them from the veins. This keeps their ſides ſeparate, although they may contain no blood; and theſe veſſels are the only tubes, excepting thoſe of a cartilaginous nature, which remain permanently open when undiſtended. In conſequence of this property, an artery, when cut acroſs, in the dead ſubject, preſents a circular area, and this diſtinguiſhes it from a vein, the ſides of which collapſe. The aorta indeed, and ſome of its larger branches, may occaſionally preſent an oval appearance, when thus divided, from the preſſure of the ſurrounding parts. Their elaſticity enables theſe veſſels to reſtore themſelves after their ſides have been preſſed together; or when the whole tube has been bent. By enabling the veſſel to give way when the blood is thrown into it, this property produces the locomotion conſequent on the contraction of the heart; and provides for the reſtoration of the tubes to its former ſtate.

Properties reſulting from the Organization of the Part.—1ſt. *Extenſibility.* This muſt be conſidered in two points of view: 1ſt, as it acts in the tranſverſe; and, 2dly, in the longitudinal direction. Arteries yield but ſlightly in the former of theſe ways. Attempts at dilating them by injections of water, air, or other matters will ſcarcely extend them beyond their natural calibre. If the force be continued, the two inner coats burſt, and the cellular covering forms a cyſt; in ſhort, the effect is repreſented by ſome as exactly analogous to what occurs in aneuriſms. When a large artery is tied in a living animal, the blood, ſtrongly propelled againſt the ligature, muſt exert a dilating force on the arterial parietes, yet there is hardly any ſenſible dilatation. The arterial tiſſue will yield, if the diſtending power be applied more gradually: thus we frequently ſee the arch of the aorta enlarged, and dilatations occurring which form true aneuriſms. But the extent of this enlargement is confined within narrow limits by the brittleneſs of the arterial coats. The arteries enjoy a greater power of diſtenſion in the longitudinal direction; hence we ſee the tied end of an artery protruded at each pulſation, and hence we are enabled to draw out the divided extremity from the face of a ſtump.

Athough there ſeems hardly any perceptible extenſion of the arterial tubes in the tranſverſe direction in the living body, they admit of conſiderable elongation in the dead ſubject. "Having," ſays Mr. Hunter, "cut off a portion of about an inch in length, from the aſcending aorta, at half an inch above the valves, and having ſlit it up, it meaſured tranſverſely two inches and three quarters, but, when ſtretched to its full length, three inches and three quarters, having gained rather more than one third, and having required a force equal to the weight of one pound ten ounces to produce this effect." On the Blood, p. 113.

Extenſion in the tranſverſe direction is reſiſted by the fibrous coat, and in the longitudinal by the internal and cellular covering.

2dly. *Contractility* muſt be conſidered, like the preceding property, in two points of view. It is much more ſtrongly marked in the tranſverſe direction, than the extenſibility. When an artery is no longer diſtended by blood, it contracts upon itſelf, and that to a degree proportionate to the diminiſhed quantity of its contents. We may explain the following phenomena by this general law. 1ſt. The ductus arterioſus and the umbilical arteries gradually contract after birth, until they are converted into impervious cylinders by the union of their ſides. That portion of an artery, which is included between a ligature and the firſt collateral branch, undergoes exactly the ſame change. 2dly. A portion of artery (the carotid) included between two ligatures and emptied by a puncture, immediately loſes one half of its calibre. 3dly. In a dog, in whom an artificial plethora has been produced by tranſfuſion of the blood, the diameter of the arteries is nearly double that which they poſſeſs in an animal of the ſame ſize deſtroyed by hæmorrhage. And two animals of equal ſtature deſtroyed, the one by hæmorrhage, and the other by aſphyxia, preſent the ſame differences. Will not this view ſufficiently account for the ſmallneſs or largeneſs of the pulſe? 4thly. The very different diameters of the arteries in ſubjects of ſimilar ſtature after death depend on the quantity of blood contained in theſe veſſels at the time of death. Hence injection, by diſtending them artificially, deſtroys theſe differences. If the animal be bled to death, its arteries exhibit the greateſt degree of contractility, and the amount of this, in various parts of the ſyſtem, has been aſcertained by Mr. Hunter from actual admeaſurement of the veſſels in a horſe killed in this manner. He removed from the body very carefully ſections of various arteries, and meaſured them, when ſlit open, ſo as to aſcertain the greateſt degree of contraction; he then ſtretched them tranſverſely, and meaſured them when elongated as much as poſſible; laſtly, he meaſured them a third time, in the ſtate to which they recovered by their own powers, and which may perhaps be repreſented as the natural condition of the artery. He found that the power of recovery was greateſt near the heart, and gradually diminiſhed towards the ex-

tremities of the body. In the following tabular view of theſe experiments, the figures of the firſt column ſhew the meaſurement of the artery in its contracted ſtate; thoſe of the ſecond, the meaſure at the point of greateſt contraction; of the third, in the ſtate of recovery; and in the fourth, the degree of contraction in parts of the whole artery.

	Inches.	Inches.	Inches.	
Aorta aſcendens	$5\frac{6}{12}$	$10\frac{6}{12}$	6	$\frac{1}{11}$
Aorta deſcendens at the firſt intercoſtal	$4\frac{1}{2}$	$7\frac{6}{12}$	$4\frac{6}{12}$	$\frac{1}{17}$
Aorta deſcendens at its loweſt part	—	—	—	$\frac{1}{18}$
Iliac artery	2	—	$2\frac{2}{12}$	$\frac{1}{6}$
Axillary	1	—	$1\frac{1}{8}$	$\frac{1}{8}$
Carotid	$\frac{6}{12}$	$1\frac{4}{12}$	$\frac{10}{12}$	$\frac{3}{5}$
Crural	$\frac{10}{12}$	—	$1\frac{2}{12}$	$\frac{1}{3}$
Humeral	$\frac{7}{12}$	—	$\frac{9}{12}$	$\frac{1}{7}$
Radial	$\frac{3}{4}$	—	$\frac{6}{12}$	The whole.

5thly. In longitudinal wounds of the arteries, the cut ends of the circular fibres ſeparate from each other, and leave a vacant ſpace between them.

Bichat complains that moſt authors have confounded the property which we are now conſidering, with irritability. He obſerves, "that in all the preceding caſes there is no neceſſity for applying any ſtimulus to the arterial tiſſue; the only condition requiſite is the ceſſation of the diſtending force, and this circumſtance particularly characterizes the contractility which reſults from organization. It is moreover evident that this property is exhibited after death, although leſs ſenſibly than during life; whereas, on the contrary, every kind of irritability ceaſes in a few hours after the ceſſation of life." Mr. Hunter is one of thoſe, to whom the preceding obſervations of Bichat are applicable. He ſpeaks familiarly of the *muſcular* coat and *muſcular* action of arteries; as if theſe points were moſt clearly aſcertained; and he adduces the experiments performed on the arteries of a horſe bled to death, which we have quoted above, to ſhew the different degrees of muſcularity poſſeſſed by different arteries.

The contractility in the longitudinal direction is leſs ſtrongly marked than in the tranſverſe; but it exiſts to a certain degree. Thus, when an artery is divided between two ligatures, the two ends are retracted into the cellular ſheath, and become ſeparated by a certain interval. This retraction occurs in amputation, but, as that of the ſkin and muſcles is more conſiderable, the artery remains ſomewhat projecting. A tranſverſe wound of the arterial coats produces a wide opening of the tube, in conſequence of this retraction. When an artery is extended violently, and then ſuddenly left to itſelf, it is withdrawn conſiderably into the ſurrounding ſoft parts; hence, when a part is torn away from the body, and when its arteries have conſequently undergone this treatment to a very great degree, no hæmorrhage follows.

The effect of ſtretching an artery longitudinally in the dead ſtate is different from that which reſults from applying force to it in the tranſverſe direction. Mr. Hunter made this experiment on the occaſion alluded to above; and he found that the arteries, when ſtretched longitudinally, recovered their former ſtate completely. On the Blood, p. 127.

Vital properties. Animal ſenſibility.—The following is the reſult of Bichat's experience on this ſubject. The application of a ligature ſometimes cauſes pain, but more frequently has no ſuch effect. In numerous trials on the carotid, irritation by the knife, by acids or alkalies, occaſioned no ſigns of pain; and ſimilar reſults have been obtained by numerous authors. This is a proof of the inſenſibility of the nerves of the organic life, which are diſtributed upon the arteries in almoſt every part. With reſpect to the internal membrane, the injection of a mild fluid, as of water at the temperature of the animal, is abſolutely indifferent; but irritating ſubſtances, ſuch as ink, dilute acids, wine, &c. produce a very acute pain, if we may be allowed to judge from the cries and agitation of the animals when they enter the carotid.

Animal or voluntary contractility does not belong to the arteries. Irritation of the brain, which convulſes the voluntary organs, and opium, which paralyſes them, have no effect on theſe tubes. Irritation of the cerebral nerves, or of thoſe from the ganglia, is equally incapable of affecting the arteries; neither can we influence theſe veſſels by means of galvaniſm. Hence all the obſervations of Cullen, and others, on the nervous power, and the influence of the brain on the arteries, are vague, illuſory, and contrary to experience.

Properties of the Organic Life.—Organic ſenſible contractility is manifeſtly abſent from the ſyſtem which we are now conſidering. No irritation, either of the external or internal ſurface, produces any contraction of an artery in the living animal. It betrays no ſigns of contractility when removed from the body, as the inteſtine or heart does. When the laminæ are diſſected by ſucceſſive ſtrata, they exhibit none of the quivering which is obſerved in the organic muſcles under ſimilar circumſtances. Some authors have produced contraction by means of concentrated acids; but this is the action of the ſubſtance on the tiſſue of the part which remains permanently corrugated. A ſtatement of all that can be ſaid on the oppoſite ſide of the queſtion, with references to various authors, may be ſeen in Soemmerring, de Corp. Hum. Fabrica, tom. 5. § 58.

Organic ſenſible contractility, or tonic power, is manifeſt in the arteries. In thoſe which have pulſation it is confined exclusively to the purpoſe of nutrition; but as ſoon as the influence of the heart on the blood's motion ceaſes, which is probably at the beginning of the capillary ſyſtem, this power is not merely concerned in the nutrition of the vaſcular parietes, but alſo carries on the circulation. Organic ſenſibility always exiſts with the preceding contractility, and amounts only to an obſcure proportion in the large trunks.

On the Cauſes of the Motion of the red Blood.—Are the arteries active or paſſive in this buſineſs? When the phyſician examines the pulſe, does he diſcover the condition of the heart or of the arteries? From the foregoing obſervations concerning the abſence of ſenſible organic contractility, it will follow that theſe veſſels are paſſive; that their motion is imparted to them from the heart; that the latter organ is the ſource of the impulſion which theſe veſſels merely obey; conſequently, that the ſtate of the pulſe, in almoſt all caſes, indicates the condition of the vital powers of the heart, and not of the arterial ſyſtem, the vitality of which is not more excited when the pulſations are the moſt frequent and forcible, than when they are feweſt and moſt feeble.

If the pulſe were produced by vital contraction of the arteries, it ſhould be irregular below an aneuriſmal tumour, ſince the diſeaſed condition of the arterial tiſſue would naturally be expected to deſtroy or conſiderably modify this power. But no ſuch effect is obſerved; while, on the contrary, organic diſeaſes of the heart conſtantly affect the pulſe. Oſſification of an artery does not obſtruct the blood's paſſage, but the change has the mechanical effect of preventing us from feeling the pulſe. A ligature placed on an artery,

artery, by intercepting the influence of the heart, ſtops the pulſe in the veſſels beyond the ſituation of its application. That the phenomenon of the arterial pulſations is not owing to any contraction of the veſſels is proved by the following curious experiments of Bichat. "Take the arm of a dead ſubject and place it in warm water; then infert a ſmall tube in the brachial artery, and fix its other extremity in the carotid of a large living dog. Immediately the heart of the animal will propel the blood into the dead limb. The artery pulſates leſs ſtrongly indeed than in the living ſtate, but quite ſufficiently to admit of the effect being felt even through the integuments. When the red blood is made to circulate in the veins by a contrivance of this kind, there is an effect produced ſenſible to the finger, and the fluid moves with conſiderable rapidity. The latter experiment alone is almoſt ſufficient to prove that the heart is the only agent by which the blood is made to move through the arterial tubes. In fact this fluid flows uniformly through the veins, becauſe the capillary ſyſtem ſupplies them uninterruptedly, while it is thrown out of an artery by ſucceſſive jets, which ariſe from the contractions of the heart. Now, if you open a vein in which you have introduced red blood by means of a bent tube connected with the artery of another animal, the ſtream of blood will exhibit the jets correſponding to the contractions of the heart. If this experiment be inverted, that is, if a bent tube be adapted to a vein and an artery in ſuch a manner that the blood of the former may be introduced into the latter, the artery will loſe its pulſation, unleſs it ſhould be kept up by the collaterals, which will not be the caſe if large trunks, ſuch as the crural, and its correſponding vein, be ſelected. The reſult of all theſe experiments, which I have frequently repeated, ought to have been exactly the converſe of their actual reſult if the arteries participated in the circulation by their vital powers. The action of the heart will drive the blood through dead tubes of conſiderable length adapted to the arteries. Remove a portion of the carotid, and infert a pipe in its open ends: the blood will traverſe this, and occaſion the arteries to pulſate beyond the ſituation of the experiment. Infert the end of a tube in the carotid of a dog towards the heart, and its oppoſite extremity in the crural or carotid of another dog in the direction leading from the heart: the heart of the firſt will conſtantly produce pulſation in the arteries of the ſecond. If a tube, having a bag of ſome kind at its end, be inſerted in an artery, the blood immediately fills the bag, in which there will be a kind of pulſation at each action of the heart, analogous to what is felt in an aneuriſmal cyſt."

A further proof that the pulſe is produced by the heart's action, is afforded by ſome experiments of Bichat mentioned on another occaſion. He expoſed the carotid artery and the heart by a ſection of one ſide of the cheſt, in the ſame animal; the other ſide ſtill remained for reſpiration. The pulſe was at firſt hurried, as the contact of the air accelerated the contractions of the heart; but, in a little time, the motions grew weaker, and were ſoon performed by a general quivering of the fibres. The pulſe underwent a correſponding change; when the convulſive motion took place, the beating of the artery was converted into a kind of undulation, or weak oſcillation, which is the precurſor of the total ceſſation of all motion.

"Nature," ſays the ſame author, "has ſelected, for the compoſition of the arteries, a tiſſue in which the vital properties are indiſtinctly marked. In proportion as thoſe of the heart are remarkable for their intenſity, are the arteries conſpicuous for the oppoſite reaſon. In this reſpect they muſt be claſſed with the cartilaginous, fibrous, fibro-cartilaginous, and ſimilar ſyſtems. Nature ſeems to have organized the arteries in this manner, that their motions might not diſturb the unity of the impulſe produced by the heart. Suppoſe their vital powers had reſembled thoſe of the inteſtines; a convulſive action of the aorta or the large trunks might have ſtopped the circulation, and produced the moſt alarming effects by counteracting the exertions of the heart. The more attentively things are examined, the more perfectly ſhall we be convinced of the neceſſity that there ſhould be only a ſingle impelling agent for the arterial ſyſtem, and that the latter, conſtantly inert, ſhould not have the power of arreſting the motions of the contained fluid."

The action of the heart on the red blood ceaſes, according to Bichat, in the general capillary ſyſtem, where the place of its influence is ſupplied by the tonic powers of the ſmall veſſels. "In the trunks, the branches, and the ſucceeding diviſions, according to the opinion of this phyſiolgiſt, the blood is moved only by the heart; in the ſmall ramifications the vital action of the arteries concurs with this force in keeping up the blood's motion; and, laſtly, in the general capillary ſyſtem the vital action of the veſſels is the only power employed.

"The pulſe, therefore, is only obſerved in its greateſt extent in the firſt order of tubes; it is ſenſibly weakened in the ſecond; and entirely ceaſes in the capillary ſyſtem. In the large trunks, the impulſe produced by the contraction of the heart is ſo ſtrong, and the column of blood ſo large, that the inſenſible contractility has no effect. Irritability alone might act in this ſituation, but that property does not exiſt in the veſſels. In the ſmall tubes the effect of the heart's action is ſenſibly diminiſhed, and the blood, divided into very ſlender ſtreams, requires, for the maintenance of its motion, merely a kind of oſcillation, or inſenſible vibration of the vaſcular parietes. This compariſon ſhews us the eſſential diſtinction of the two kinds of organic contractility. The one is exerted on the fluids, when accumulated in a maſs, as on the blood, aliment, urine, &c.: the other moves them when divided into ſmaller portions, and preſides over the capillary circulation, exhalation, and ſecretion. Wherever there is a large cavity, as in the heart, ſtomach, inteſtines, &c. the former is eſpecially obſerved, while the ſecond is confined to the caſe of ſmall veſſels. Hence, while the blood continues in maſſes, as in the heart, and large arteries, the firſt of theſe powers, which reſides in the heart, produces its motion; when it is in ſmall ſtreams, the inſenſible contractility of the veſſels keeps up the movement."

Phenomena produced by the Action of the Heart.—As the arteries are always full of blood, the impulſe produced by the contraction of the left ventricle is felt at once through the whole ſyſtem to its very extremities. If a tube, dividing into a ſeries of branches, which were again divided for any number of ſucceſſive times, and completely filled with fluid, were connected to a ſyringe, the depreſſion of the piſton would cauſe an efflux from all the open branches at that very inſtant. In the ſame way, if you ſtrike the end of a long beam, the motion is quickly communicated to the oppoſite extremity. Hence, if the arteries of a dead body are filled with water, and an additional quantity is forced in by means of a ſyringe, ſome will be projected at the ſame inſtant from the tibial, or any other veſſel which may be opened. The repreſentation of a wave of blood, conſiſting of two ounces, expelled by the contraction of the ventricle, and ſucceſſively paſſing through the various parts of the arterial ſyſtem, which proceeds on the ſuppoſition of the arteries being empty when the heart contracts, while in fact they are full, is calculated to convey a notion of the ſubject altogether erroneous.

If an artery be opened far from the heart, each jet of blood will correſpond to the contraction of the ventricle,

becauſe

becauſe that contraction throws the blood from the orifice of the veſſel. But, if this fluid were ſent to the extremities of the body by contractions of the arteries, the contracted and relaxed ſtates of theſe tubes ſhould alternate with the correſponding conditions of the ventricle, and conſequently, each jet of arterial blood ſhould take place when the ventricle is dilated, which is contrary to the fact.

In the common deſcriptions of the circulation we are informed that the heart, by its contraction, propels the blood into the aorta, which is then dilated; and that in the ſucceeding period of time the aorta contracts to ſend it on to all parts of the body. But this latter time does not exiſt at all. If a large artery be laid bare and obſerved, it will be ſeen to riſe at each pulſation, but to undergo hardly any dilatation; nor does it contract to any greater degree. Contraction of the left ventricle, general movement of the whole maſs of arterial blood, and paſſage of this blood into the capillary ſyſtem, are three circumſtances which occur at the ſame moment. "We may derive," ſays Bichat, "a very exact idea of the circulation by examining the meſenteric arteries of a living animal, through the peritoneum. At each pulſation they appear to be raiſed at once from their origin to their extremities. No correct notion of this ſubject can be acquired by conſidering the wave of blood as extending at each contraction through the arteries, and arriving ſucceſſively at various parts of the ſyſtem. All authors ſpeak at length of the progreſs of the arterial fluid, yet in no point is there more doubt and obſcurity, becauſe they all proceed on a falſe principle. It is not the freſh portion of blood expelled from the ventricle that enters the capillary ſyſtem at each contraction of the heart, but that which was neareſt the capillaries in the arteries. Hence an interval of time ſeparates the departure of the blood from the heart from its arrival at the capillary ſyſtem, during which it remains, for a certain number of contractions, in the arteries. According to this mode of conſidering the arterial part of the circulation, which is the only true and admiſſible one, the windings of theſe veſſels cannot produce any retardation. I regard alſo, as entirely deſtitute of foundation, all the remarks contained in phyſiological writers concerning the cauſes of retardation in the courſe of the blood, occaſioned, 1ſt, by its paſſage from a narrower into a wider ſpace, and by the conical form of the arterial ſyſtem in general; 2dly, by friction againſt the ſides of the containing tubes; 3dly, by the angles; 4thly, by the anaſtomoſes, &c. &c. All theſe remarks would hold good if the arteries were empty at the moment of contraction, becauſe the blood would then really have a progreſſive motion; but, in the general and inſtantaneous ſhock, which the maſs expanded through the whole ſyſtem experiences, theſe cauſes are manifeſtly ineffacious. I ſtill return to the trivial, but illuſtrating compariſon of the ſyringe. Suppoſe a tube ſhould be adapted to it with a thouſand turns, angles, and inequalities; if this tube and the ſyringe are full, the depreſſion of the piſton will cauſe the water to flow out at the open end juſt as ſoon as if the canal had been ſhort and ſtraight. So true is it, that all the cauſes of retardation which might affect the blood's motion if the arteries were empty, do produce no ſuch effect in the ordinary ſtate of the veſſels, that numerous judicious obſervers, who admitted the retardation in their reaſonings, have ſeen in their experiments that the motion was uniform throughout, and the ſame in the branches as in the trunks. The pulſe occurs at the ſame time in all parts of the arterial ſyſtem. How could this happen if the deſcribed retardation actually took place? The progreſs of phyſiology concerning the circulation has been much obſtructed by the current notions concerning the velocity of the blood's motion in the arteries. Of this indeed we can form no true eſtimate, becauſe the motion is not progreſſive, and the blood does not *flow*, properly ſpeaking, but is puſhed ſuddenly by a gentle ſhock, which cannot be ſubjected to calculation."

We take this opportunity of ſtating, that the application of the laws of the various branches of natural philoſophy, and of the mathematical ſciences to phyſiology, in which the opinions juſt animadverted on took their riſe, does not ſeem to us at all calculated to advance our knowledge of the animal economy. Not that the living body is exempted from an obedience to theſe natural laws, which regulate matter and motion in other caſes; but becauſe their operation is conſtantly modified by the living powers, and the data, on which calculation ought to be founded, are themſelves by no means ſettled. On this point, the ſentiments of Senac, expreſſed in the preface to his "Traité de la Structure du Cœur, de ſon Action, & de ſes Maladies," exactly coincide with our opinions. "Phyſicians who, in ſpeaking of their art, are conſtantly recurring to mechanics, and ſprinkle their works with calculations, are only charlatans, or men of heavy and ignorant minds. They endeavour to deceive by aſſuming the ornaments of a ſcience foreign to medicine, and they incur, without ſuſpecting it, the contempt of true geometricians. What a contraſt do we ſee between the bold calculations of ſome phyſicians, and the modeſty with which the moſt enlightened calculators ſpeak of the operations of living bodies!" According to D'Alembert, in his admirable Treatiſe of Hydrodynamics, "the mechaniſm of the human body, the velocity of the blood, and the action of this fluid on the containing veſſels cannot be brought under any theory: we are ignorant of the influence of the nerves, the elaſticity of the veſſels, their various capacities, the tenacity of the blood, and the different degrees of heat which it poſſeſſes. If each of theſe circumſtances ſhould be known, the great number of elements, which would enter into ſuch a theory, would probably conduct us to impracticable calculations. It would be the moſt complex caſe of a problem, which is extremely difficult of ſolution in its moſt ſimple ſtate. When the operations of nature are too complicated to be ſubmitted to our calculations, experience is our only remaining guide, we can only ſupport our reaſonings by inductions from numerous facts. The notion that the ſprings of the human frame can be developed by means of algebra and hypotheſes, can be entertained only by idle phyſicians. Theſe ſprings are unknown, multiplied, combined; the moſt juſt calculations on this ſubject can merely appreciate our ignorance." P. 34.

When the contraction of the left ventricle propels the blood into the arteries, theſe tubes are ſlightly dilated; a general locomotion takes place, cauſing the pulſe; and ſome red blood paſſes into the general capillary ſyſtem. Theſe circumſtances occur, when the finger feels the arterial pulſation, at the diaſtole of the tube. In the following inſtant the ventricle is relaxed, that it may be filled again; the arteries, leſs full of blood, recover from the ſlight dilatation experienced juſt before; and are reſtored to their original ſituation. This is the ſyſtole, deſcribed as an active, but in reality a merely paſſive ſtate of the arterial tube. Since very little blood is thrown out of the ventricle at each pulſation, and, when the new quantity enters the arteries, ſome paſſes out at the oppoſite end, the arterial dilatation and the ſubſequent contraction are ſo ſlight in degree as to be hardly obſervable. In this view, the arterial contraction does not take place, in order to propel the blood, but it is a recovery of the veſſel from its forced ſtate, conſequent on the paſſage of the blood which diſtended it,

into

into the capillary ſyſtem. In ſhort, it is contraction from the ceſſation of extenſion.

Although this repreſentation may ſeem to deſtroy the ſources of the varieties in the pulſe, obſerved by authors, Bichat points out how the phenomena may ſtill be ſufficiently explained. "The cauſes which may affect the pulſe, may reſide, 1ſt, in the heart, the ſole agent of impulſion in their circulation. Its contractile power, augmented, diminiſhed, or ſympathetically modified, may cauſe it, with the ſame ſtimulant, to act more quickly, or ſlowly, or irregularly. Thus, organic affections inevitably alter its action. 2dly. The blood may contain various natural or morbific matters capable of exciting the heart's motion in various ways. 3dly. The general capillary ſyſtem produces many variations in the pulſe, according as it receives a greater or leſs quantity of blood. There are, then, two circumſtances to be particularly noted in the pulſe: 1ſt, impulſion of the blood, a ſudden and general motion of its maſs by the contraction of the heart; 2dly, locomotion of the arteries, an effect produced by this fluid on the arterial parietes. The firſt is the moſt eſſential point: the ſecond would be changed, if the arterial tiſſue, from the nature of which it ariſes, were no longer the ſame; it is not eſſential to the circulation.

The obſcure vital properties of the arteries occaſions them to be the ſeat of very few affections, either acute or chronic. Conſequently, they can exert only a very ſlight ſympathetic influence on other organs. For the ſame reaſons, other parts have very little ſympathetic influence on this ſyſtem. The innumerable ſympathetic variations of the pulſe have their ſource in the heart.

Progreſſive Developement of the vaſcular Syſtem containing red Blood.—1ſt. State of this ſyſtem in the fœtus. The fœtus differs eſſentially from the child, which has breathed, in this reſpect, that its two grand vaſcular ſyſtems form, in truth, but one; ſince the foramen ovale and canalis arterioſus form immediate communications between them. The blood is all of one kind in the fœtus. Bichat aſcertained this fact by examining guinea pigs while ſtill in the uterus: all their veſſels contained venous blood, at leaſt as far as could be judged by the colour. He repeated the obſervation, with the ſame reſult, on the pregnant bitch. Accoucheurs have always found the blood of the umbilical veſſels to preſent the venous colour.

The preſence of black blood in the ſyſtem of red blood in the adult cauſes the moſt dangerous ſymptoms, and ſoon produces aſphyxia and death: yet it circulates with impunity in the arteries of the fœtus. Probably there is ſome difference in the properties of the black blood in theſe two caſes. It gives an unctuous feel to the touch in the fœtus, which is not produced in the adult. It is never found coagulated in the dead ſubject, but fluid, like that of animals which have been deſtroyed by aſphyxia. Fourcroy conceives that it does not poſſeſs fibrine, nor phoſphoric ſalts: and aſſerts that it does not aſſume the crimſon colour on expoſure to air. Beſides theſe differences in the nature of the blood, we muſt advert alſo to the great difference in the functions of the fœtus and adult; and we ſhall find, on the whole, that no exact parallel can be eſtabliſhed between them with regard to effects produced by the black blood.

Yet, though the blood in all parts of the fœtus is uniform in its nature, there is a kind of ſeparation in the general maſs, firſt clearly pointed out by Sabatier, and which we have deſcribed in the article CIRCULATION. From this view, we may eſtabliſh the exiſtence of two ſyſtems, very different from thoſe which belong to the adult. The firſt has its origin in the capillaries of the abdomen, of the lower limbs, and of the placenta: its common trunks are the inferior vena cava, and the four aſcending branches of the aorta: its central organ is the left ſide of the heart, and its termination is in the capillaries of the head and upper limbs. The ſecond ariſes in the laſt-mentioned capillaries; its common trunks are the ſuperior cava and the deſcending aorta; its impelling agent the right ſide of the heart; and its termination the capillaries of the lower parts of the body, and the placenta. We have explained, in the article CIRCULATION, how the parts are changed from their fœtal arrangement, to that which is ſeen after reſpiration has begun: the deſcription of the umbilical veſſels, and the canalis arterioſus, will be found under EMBRYO.

Bichat conceives, that thoſe peculiarities which diſtinguiſh the fœtal circulation, do not undergo a ſudden revolution at the time of birth, but that there is a gradual change towards the ſtructure of the circulating organs, as they are found in an individual which has breathed before birth. "The two portions of blood are almoſt completely ſeparated in the firſt months of fœtal exiſtence: all that which comes through the inferior vena cava is ſent into the aſcending aorta, while that of the ſuperior cava goes into the deſcending. As the time of birth approaches, theſe two quantities begin to be mixed, and the circulation aſſumes a middle kind of mechaniſm between thoſe of the early months, and of the adult. The foramen ovale, and the ductus arterioſus, are already contracted before birth, and the circulation approaches towards the ſtate in which it is found after reſpiration has commenced. The introduction of red blood into the economy is the moſt ſtriking phenomenon that occurs after birth. We ſhould form an erroneous conception of the ſubject, if we ſuppoſed a ſudden change at birth. Examinations of the foramen ovale, and canalis arterioſus, at different periods of pregnancy, will ſhew us that they contract ſucceſſively; ſo that if the child remained beyond its natural term in the uterus, and the ſame proceſſes were continued, the blood would at laſt circulate as it does in the adult, merely from the pulmonary to the general capillary ſyſtem, and *vice verſâ*. But it would be of one uniform colour. I do not mean to ſay that reſpiration does not invite towards the lungs the remainder of the blood which uſed to paſs through the canalis arterioſus; but this derivation can affect a part only of the blood of the pulmonary artery: one portion of this already paſſes through the veſſels of the lungs before birth, although the cells were empty. There is a conſtant relation between the quantity of blood ſent by the right ventricle to the lungs, and that which the left propels into the lower parts of the body. As the former increaſes, the latter becomes more abundant, and this manifeſtly exceeds the quantity which goes to the upper parts. The proportion of the blood brought by the inferior cava, which mixes with that of the ſuperior, and paſſes into the right ventricle; that which from the right ventricle traverſes the lungs and returns to the left ventricle; and that which goes from the left ventricle into the deſcending aorta, are always increaſing in proportion as the time of parturition draws near."

The vaſcular ſyſtem, in general, is remarkable for its great developement in the fœtus. The arteries are larger in proportion to the other parts, and correſpond in this reſpect to the volume of the heart. The ſize of theſe veſſels, however, is in proportion to the relative bulk of the parts which they ſupply: thus thoſe of the pelvis and lower limbs are very ſmall.

The arterial tiſſue is more pliant in the fœtus than in the adult; and ligatures conſequently cut it leſs eaſily. The number of the vaſa vaſorum ſeems greater; they are, however, more conſpicuous. In the early months, when the ſubſtances

ſubſtances compoſing the arteries cannot be diſtinguiſhed, theſe veſſels are remarkable for their firmneſs, in which reſpect they exceed the ſurrounding organs.

2dly. *State of this Syſtem during the Time of Growth.*—At the moment of birth two great revolutions take place in the ſyſtem of red blood; *viz.* a mechanical one, if we may be allowed to uſe that expreſſion, in the courſe of the blood; and another of a chemical nature in the compoſition of this fluid. The commencement of reſpiration may be referred partly to the general convulſive kind of motion, produced by the acute ſenſations conſequent on the remarkable change in the poſition of the child, and partly to inſtinct. The commencement of reſpiration attracts towards the lungs the blood which paſſed formerly through the canalis arteriaſus. Such is the mechaniſm of the foramen ovale, that when the two auricles contain an equal quantity of blood, their contraction preſſes together the ſides of this aperture, and thus prevents the paſſage of the blood through it. "Although," ſays Bichat, "this aperture be ſtill open at the time of birth, the black blood ceaſes to paſs through it; I go ſtill farther, and affirm, that the opening often continues throughout life. Many authors relate examples of this; and I have met with a great number. The diſpoſition of the ſides of the opening is ſuch that the blood cannot paſs. When the two auricles contract together, the blood, which is preſſed from without inwards, applies the overlapping edges cloſely together, and cuts off the communication between the two cavities. The adheſion of the parts, in moſt caſes, is very weak; they are rather agglutinated than continuous, ſo that they may be eaſily ſeparated by the preſſure of the handle of a ſcalpel, and hardly any trace of rupture remains. Authors may, therefore, ſave themſelves the trouble of explaining how perſons may live when the foramen ovale is open; the courſe of the blood is juſt the ſame as if the aperture did not exiſt." The ſame fact is diſtinctly ſtated by Soemmerring, as a circumſtance of not unfrequent occurrence. (De corporis humani fabrica, tom. 6. § 14.) When the blood no longer traverſes the canalis arteriaſus, that tube is quickly cloſed in conſequence of its organic contractility: it is converted into an impervious and firm cylinder, which fixes the aorta and pulmonary artery, to a certain degree, in their reſpective poſitions. The obliteration of the other opening is effected in a different manner; not by a contraction of the two ſemicircular folds between which it is obliquely ſituated at the time of birth. It ſeems to be an effect of the preſſure exerciſed in oppoſite directions upon the middle ſeptum of the auricles by the blood which each contains. The events, as we have ſeen above, may not take place; but the contractility of the arterial canal being invariably exerted when the tube is no longer diſtended, that veſſel is invariably obliterated. The obliteration of the umbilical vein and arteries is coeval with theſe changes.

When the function of reſpiration is completely eſtabliſhed, the lung is in oppoſition to the whole body: it ſends blood to all the parts, which return it again. The limits between the two vaſcular ſyſtems are then rigorouſly fixed.

"For a long time after birth, the vaſcular ſyſtem of red blood ſtill predominates, is ſtill remarkable for its great development, and for the great number of its branches. Red blood penetrates into a much greater number of theſe, than will receive it in the ſequel. Diſſection of living animals at different ages will ſufficiently ſhew that this ſyſtem contains a much greater quantity of blood in young than in old ones: ſo that the proportion of the ſolids and fluids at one end of extreme is the reverſe of that which exiſts at the other. The latter are the moſt abundant as we draw nearer to the moment of conception: the former predominate towards the end of life.

"The predominance of the ſyſtem of red blood continues marked until the end of growth. That this ariſes from the functions of nutrition and growth is very clear; the arteries in the adult contain only what is required for the former of theſe; and the latter is ſuperadded in the child. Hence, increaſed calibre is neceſſary in the child, and injections exhibit this fact.

"As the child advances, the various parts of this ſyſtem arrive at thoſe proportions with reſpect to each other, which we find in the adult."

3dly. *State of the Syſtem after the Growth is finiſhed.*—About the epocha of puberty, the height of the body is completed, but it ſtill continues to grow in bulk. The generative organs now come into play, and that portion of the arterial ſyſtem, which belongs to them, receives conſiderable additional developement. At the ſame time the vital energy of the lungs is augmented, and theſe organs are the moſt frequent ſeat of diſeaſe. At the ſame time the diſeaſes produced by arterial plethora ſhew themſelves; and theſe marks of abundant blood ſeem to admit of a ſatisfactory ſolution from the ceſſation of growth. Gradually an equilibrium is eſtabliſhed between all the organs, and the arteries acquire that proportionate volume, which they will retain afterwards. Subſequently to the end of growth, the arteries are increaſed in denſity and thickneſs. Their fibres become more clearly marked, their elaſticity is increaſed, and their plumpneſs diminiſhed. The denſity of theſe tubes holds a relation to the fleſhy fibres of the heart; in proportion as the latter becomes capable of propelling the blood more forcibly, are the former rendered able to reſiſt this force.

4thly. *State of the Syſtem in old Age.*—The number of arterial twigs is much diminiſhed. The heart, loſing its energy, propels leſs blood with leſs energy; and the general vibration produced in the whole ſyſtem is leſs felt at the extremities of the ſyſtem. The ſmall branches ſeem to be gradually obliterated. Hence, on ſeparating the pericranium or dura mater, very few drops of blood are perceptible; the ſkin, rendered dry and hard, no longer exhibits the ruddy tint of the preceding ages, particularly of youth; the texture of a bone affords hardly any blood; the mucous ſurfaces grow pale; and the muſcles loſe their colour. Every practical anatomiſt knows that injections ſucceed leſs perfectly in proportion as the ſubjects are more advanced in age; that the arterial trunks only are filled in very old bodies, and the fluids never penetrate into the ſmaller branches; and that young ſubjects exhibit circumſtances exactly contrary.

This diminiſhed quantity of red blood in the old [illegible] ariſes from the relative condition of his nutrition, which [illegible] function has almoſt ceaſed; and thus circumſcribed, together with the weakneſs of its motion, accounts for the ſlow rate of excitation of all parts in old perſons. If the functions of our organs diſplay a vigour and activity proportioned to the quantity of fluid and the force of its motion, we ſhould expect them to be characterized in childhood by a vivacity which would form a contraſt to the languor and diminiſhed energy of old age.

The arterial tiſſue becomes more and more condenſed as the individual advances in years, and the lamina of the fibrous coat appear more dry. The arch of the aorta is almoſt the only part which experiences nearly always a degree of enlargement in old age;—an extenſion without the rupture of fibres. The pulſe is remarkable for its ſlowneſs, a character exactly oppoſite to that of infancy. It will be underſtood, from what has been already ſtated, that the ſeat of this variation is in the heart.

Arterial

Accidental Development of the System.—The formation of new arteries seems to take place in some circumstances; as in the case of adhesions in the cheft or abdomen, &c.; but there has been no minute inveftigation of this fact. Thefe veffels are dilated, when any obftruction is formed to the paffage of the blood by the ordinary channels; as when the artery of a limb has been tied in the operation for an aneurifm, or when a fwelling of this kind has undergone a fpontaneous cure. A fimilar dilatation generally takes place when tumours are formed, particularly fuch as are attended with acute pain. In amputating a thigh, for diftafed knee-joint, the arteries requiring ligatures are very numerous, if the diftafed part be at the time in a ftate of aktive inflammation.

Pulmonic Syftem containing Black Blood.—The red blood circulates in a fingle fyftem, of which the branches communicate together in all parts: the black, on the contrary, is contained in two infulated fyftems, viz. the general, and the pulmonic. The veins will be the principal objeft of our attention in this diviſion of the fubjeft, as the pulmonary artery is analogous in its ſtructure and ramifications to the arteries of the preceding fyftem, and the central cavities will be conſidered in the general account of the heart.

The veins originate in the general capillary fyftem, and are produced in no organ, into which arteries do not penetrate; as in tendons, cartilages, &c. This clearly proves that blood is not formed in the general capillary fyftem; it depoſits there the principles, from which its red colour was derived, and perhaps derives new ones; in a word, it is modified, but never created there. It is not ſo eaſy to diſtinguiſh the veins, at their origin from this fyftem, as to trace the arteries into it; ſince the valves prevent injections from penetrating. Hence ſubjects, who have died of aſphyxia, apoplexy, &c. are the moſt favourable for obſerving the minute venous ramifications. On ſuch occaſions, we can ſhown that they are here divided into two orders, of which one accompanies and the other is diſtinct from the arteries. In moſt organs veins go out in the ſame ſtructure as which arteries enter; however, there are ſome exceptions to this rule. The arteries of the brain enter below, and the veins go out above; the former veſſels enter at the lower part of the liver, and the latter eſcape behind. Theſe diſtinctions have no effect on the circulation. Beſides the veins, which correſpond to the arteries, there is an order of theſe veſſels which have a diſtinct courſe. The organs near the ſurface of the body ſmall, as, veins which go towards the heart, together with the arteries; ſally, others which become ſubcutaneous, and form trunks, which we ſhall mention preſently. It appears from this deſcription that the veins, quitting the general capillary ſyſtem, are much more numerous than the veins which enter it. Here the diſproportion in capacity between the two ſyſtems begins.

The progreſs of the veins, after their commencement, is not uniform. In the limbs and exterior parts of the trunk they form two cheſts; an interior, following the courſe of the arteries, and an exterior, which is ſubcutaneous. A ſimilar diſtribution is ſometimes obſerved in the internal organs; thus there are ſuperficial and deep-ſeated veins in the kidneys; but generally all the veins end in thoſe trunks which accompany the arteries.

The moſt remarkable diſtinction of veins is very remarkable in the extremities and neck, where they conſtitute large trunks, ſuch as the baſilar, cephalic, baſilic, and external jugular veins. No ſuch large branches are found in the trunk; but there is a more conſiderable number of ſmaller ramifications. Thus, the external ſurface of the body exhibits a remarkable predominance of trunks containing black blood over thoſe which are filled with red blood. In the internal, as their ſides, compared to thoſe of the arteries, are thin, they may often be diſtinguiſhed through the integuments by their colour. The prominences, which they form, have a pale blue tint, made up of the dark purple of the venous blood, and the whiteneſs of the ſkin, and more diſtinct in proportion as the ſkin is thin and clear. No part of this colour reſides in the veſſels themſelves.

In the interior of the body the veins almoſt univerſally accompany the arteries. Generally a common cellular ſpace contains both the trunks of the two kinds of veſſels and the nerves. The azygos is, however, an inſulated vein. The deep-ſeated veins are more capacious than the arteries, and uſually more numerous, as in the limbs, where each artery has two correſponding venous veſſels.

It muſt be obvious, from the foregoing aſſertions, that the venous ſyſtem, taken altogether, much exceeds the arterial in capacity. This aſſertion may be eaſily verified in detail, wherever an arterial and venous trunk are found together; and it is not leſs true wherever theſe veſſels are ſeparate in their diſtribution. The area of the inferior cava is to that of the aorta, according to Haller, as ſixteen to nine; and Wintringham makes theſe proportions as 1713 to 1000. The latter author gives 191 and 100 as the proportions of the vena cava and the aorta juſt above the iliac veſſels. Haller found the ſplenic artery to be to the vein as 136 to 276; and theſe proportions are expreſſed in the renal veſſels by 614 and 1490. The ſubclavian artery was to the vein as 81 to 196, and the carotid to the jugular as 196 to 441. A deduction from various data will give us room to aſſert as a general ſtatement of the relation which the capacity of the arteries bears to that of the veins. The exceſs of the latter veſſels is rendered very obvious by injections, where both orders of veſſels are filled, as in the cadaver, the arteries are almoſt hidden by the ſuperior numbers and ſize of the veins.

The veins do not exceed the arteries in their diameter merely, but alſo in number; and the proportion of the former to the latter is threefold according to ſome. The united areas of all the veins will, therefore, far ſurpaſs thoſe of the arteries, if the former veſſels are not only more capacious individually, but alſo more numerous. Large veins plexuſes exiſt in many parts without any correſponding arteries, as under the ſkin of the extremities and neck, in the ſpermatic chord, about the bladder and generative organs, &c.

To theſe obſervations Haller objects the unnatural ſtate to which they muſt always be expoſed. If the veſſels ſhould be meaſured in the dead ſubject, the kind of death occaſions great variety in their volume. In apoplexy, aſphyxia, &c. their diameter is double what they preſent in caſes of death from hæmorrhage: hence we may give to them nearly what capacity we pleaſe, according to the mode in which we deſtroy the animal. The veins vary equally in ſize in the living ſubject, according as they are more or leſs full: they exhibit under this circumſtance prominence, and at others barely diſtinguiſhable. Whatever the ſtate of blood in diminiſhed, from whatever cauſe ariſe, the veins contract proportionably; while the arteries, or rather their more firm texture, changes in a much leſſer degree. When there is ſuch variety in the facts, the calculations founded on theſe muſt be ſomewhat vague. Their exact proportions are not however of any conſequence in explaining the phenomena of health and diſeaſe. We may be contented with the general aſſertion, that the capacity of the venous ſyſtem conſiderably exceeds that of the arterial ſyſtem: in a given time there is more blood contained in the former, than in the latter. A ſimilar obſervation may be made concerning the two lobes of the heart; the right is more capacious than the left, becauſe it contains more blood. If this

fluid be confined in a dying animal to the left cavities, while the right are emptied by punctures, the latter will appear to be the largeſt. In ordinary deaths the blood is accumulated in the right cavities, and makes them appear the largeſt.

Thus we have arrived at two ſtatements, which are generally true: 1ſt, that the great tree, which terminates the ſyſtem of red blood, is generally inferior in capacity to that by which the ſyſtem of black blood begins; 2dly, that the ſame obſervations applies to the two ſides of the heart, which correſpond to theſe.

"The caſe," ſays Bichat, "is not the ſame with the tree in which the ſyſtem of black blood ends, when compared with that in which the red-blooded ſyſtem commences. The pulmonary artery, and the veins of the ſame name, preſent a leſs conſiderable diſproportion in their capacity than is obſerved between the two kinds of veſſels in other parts; yet there is a real difference, and that is in favour of the veins. Since the artery is continuous with the veins of the body in general, and tranſmits the fluid brought by thoſe veſſels, and ſince the pulmonary veins are connected in a ſimilar manner with the arterial ſyſtem, it would probably have been expected that theſe canals ſhould correſpond relatively to each other. The phenomenon may be explained by the difference in the velocity of the blood: that fluid circulates more rapidly in the pulmonary artery, than in the veins of the ſame name, becauſe it receives the impulſe of the heart in the former caſe, but not in the latter. Hence as much blood paſſes through the artery as through the veins in a given time, although the diameter of the former is the ſmalleſt. The ſame explanation applies to the aorta and its correſponding venous trunks.

The four pulmonary veins taken together are rather larger than the aorta, which yet tranſmits all the blood that arrives through them. Becauſe the contraction of the left ventricle ſends more blood in a given time through the aorta, than paſſes through theſe veins. Hence the two circumſtances, *viz.* velocity of the blood's motion, and the capacity of the cavities in which it circulates, are in an inverſe ratio to each other in the two oppoſite trees, which form each vaſcular ſyſtem. In that of red blood there are diminiſhed velocity and greater capacity from the pulmonary capillaries to the agent of impulſion: from the latter to the general capillary ſyſtems, we obſerve, on the contrary, increaſed velocity and diminiſhed capacity. In the other ſyſtem the characters firſt mentioned prevail from the general capillaries to the impelling power: and the other circumſtances are ſeen in the ſecond part of the ſyſtem.

The capacity of the pulmonary veins, however, ſurpaſſes that of the aorta by a much ſmaller proportion, than that by which the venæ cavæ and the coronary veins exceed the pulmonary veins. The following reaſons ſeem ſufficient to explain this arrangement. As the courſe of the pulmonary veins is very ſhort, the impulſe received by the red blood from the pulmonary capillaries is more effectually exerted, and many cauſes of retardation, which affect the cavæ, are avoided. Hence greater velocity and leſs diameter in the pulmonary veins.

There can be no trouble now in underſtanding the cauſe of the numerous arrangements in the circulating organs, which have attracted conſiderable attention from phyſiologiſts: *viz.* why the ſum of the arteries coming from the aorta poſſeſſes leſs capacity than that of the veins entering the right auricle; why the four pulmonary veins exceed the artery of the ſame name; why theſe veins are not exactly proportioned to the aorta, which is continued from them; and why the coronary and venæ cavæ are ſo diſproportionate to the pulmonary artery.

If there were no impelling power in the two ſyſtems, their capacity would be uniform throughout, becauſe the velocity would be the ſame in all parts. Hence in the abdominal ſyſtem of black blood, the hepatic and inteſtinal portions of the vena portarum are of equal capacity.

The velocity of the fluid is leſs in the general and in the pulmonary veins, becauſe there is no agent of impulſion at their beginning, but merely a capillary ſyſtem. An arrangement of circumſtances, exactly contrary, explains the greater velocity in the pulmonary and the general arteries. We have obſerved, in ſpeaking of the ſyſtem of red blood, that the preſence of the impelling power at the commencement of the arteries renders it neceſſary that the organization of theſe tubes ſhould poſſeſs conſiderable powers of reſiſtance, while the abſence of ſuch an agent from the beginning of the veins allows theſe to be weaker in their ſtructure. Thus we may ſee very clearly how it happens, that weakneſs of their ſides, ſlow motion of the contained fluid, and conſiderable capacity, are attributes of the veins in both ſyſtems; and why the arteries are marked by three oppoſite characters. Hence too we underſtand, although the red and the black blood form in their whole courſe one continuous column, and although the common membrane, over which they move, be nearly the ſame in the whole extent of each ſyſtem, why the organs placed on the exterior of this membrane ſhould be ſo different.

Theſe conſiderations will lead us alſo to the explanation of the different proportions which the arteries and veins bear to each other in different parts of the body. The renal, bronchial, and thymic veins are generally ſmaller in proportion to their arteries, than the ſpermatic or hypogaſtric veins are to the correſponding arterial tubes. The blood moves more eaſily in the former than in the latter, through which it aſcends, contrary to the force of gravitation. For the ſame reaſon, the diameter of the veins exceeds that of the arteries, by a greater proportion in the lower than in the upper parts of the body, particularly at a certain age.

The veins are diſtributed in a manner analogous to the arteries, with reſpect to their diviſions and ſubdiviſions, excepting that theſe take place in an inverſe order to thoſe of the arteries. They begin by minute twigs, which are united together to form larger canals; theſe, uniting together, make larger branches, which, by their ſubſequent junctions, compoſe more conſiderable trunks. The ſmaller venous tubes are found in the interior of our organs, and are a component part of them: as theſe unite into larger branches, they are lodged in the intervals of parts, as between the lobes of the glands, the faſciculi of muſcles, &c. When they quit their reſpective organs, they join into more conſiderable branches, which form two claſſes, a ſubcutaneous and a more deeply ſeated one. The former run immediately under the ſkin, and are interpoſed in the limbs between the integuments and the faſcia: the latter are lodged in the intervals between the organs, and generally accompany the arteries. The veins of the brain have a diſpoſition peculiar to themſelves, being lodged in cavities of the dura mater, called ſinuſes.

In all ſituations theſe veſſels are much leſs tortuous than the arteries: "this circumſtance," ſays Bichat, "would prevent locomotion of the veins, even if there were an impelling agent at their commencement, and if their ſides were of a firmer ſtructure. Hence too it follows, that a ſeries of arterial tubes is actually longer than a correſponding ſeries of veins. This facilitates the motion of the black blood, by making its courſe leſs extenſive, as well as by avoiding the retardation, which a tortuous arrangement would create in

this ſyſtem, where there is no impelling power, as in the arteries, to overcome ſuch an obſtacle."

The veins are united ultimately into a certain number of trunks, opening into thoſe which terminate in the right auricle of the heart: theſe are the internal jugular, ſubclavian, and azygos veins above, and the iliac below. Like the arterial trunks, they are placed deeply, and protected by the ſurrounding organs from external injury, ſince a wound might produce fatal hæmorrhage.

No conſtant rule is obſerved as to ſize, in the union of the veins; ſmall twigs often ending in large trunks. The angles of junction vary, being ſometimes right and ſometimes obtuſe, but moſt frequently acute. "In the diſtribution and number of theſe veſſels," ſays Haller, "there is much more variety than in the arteries; and ſo inconſtant are the arrangements of nature in this ſyſtem, that, although I have proſecuted the courſe of the arteries minutely, in all parts of the body, I could never undertake the labour of a ſimilar inquiry into the diſtribution of the veins. It would be neceſſary to give almoſt as many deſcriptions as there are ſubjects; ſuch at leaſt would be the caſe in the extremities, face, head, and neck, while their courſe in the viſcera is tolerably regular and like that of the arteries." Elem. Phyſiol. lib. 2, ſect. 2, § 13.

A vein is cylindrical, when examined in a part where it receives no branch. It appears flattened on the dead body, ſince its ſides are collapſed in conſequence of the abſence of blood: but if it be diſtended, it regains its original form. In the living ſubject the form of the veins is round. A vein, traced from the extremity of the body to the heart, is conical, with the baſis of the cone at the heart, and its apex turned towards the general capillary ſyſtem. Yet there is an exception to this obſervation, ariſing from dilatations of theſe veſſels in particular inſtances: the vena cava is enlarged juſt under the diaphragm, the internal jugular vein exhibits a ſimilar enlargement, &c. The venous ſyſtem forms three trunks, the cava ſuperior and inferior, and the coronary vein: theſe have their apex in the right auricle, and their baſis in the general capillary ſyſtem. Anatomiſts give this repreſentation of the venous ſyſtem, becauſe, as in the arteries, the ſum of the branches exceeds in capacity the trunk, formed by their union. As the area of the aorta is very much leſs than the ſum of the united areas of all its branches, we ſhall find that the ſame compariſon holds good of the vena cava and its branches. Haller ſays that he finds the ratios of the trunks to the branches to be nearly the ſame as in the arterial ſyſtem. Bichat ſtates that the proportions are not ſo conſtant as in the arteries: that the ſum of the branches, in certain inſtances, far exceeds the area of the trunk, while it is leſs in others. He refers this, in great meaſure, to the varieties in the ſtate of the veſſels produced by the quantity of contained blood. If the circulation through the lungs have been obſtructed, accumulation takes place in the right cavities of the heart, and then in the large venous trunks: on the contrary, when a limb has been long in a perpendicular poſition, in the living body, as the leg in ſtanding, the branches are much enlarged. Since the relation of the trunks to the branches is thus ſo conſiderably expoſed to cauſes of variation, and ſuch differences may be found in this reſpect according to the mode of death, and the diſeaſes which have preceded it, we may neglect all attempts at exact calculation, which could not lead to any uſeful reſult.

The veins communicate together more freely than the arteries. In the ſmaller ramifications the anaſtomoſes are ſo numerous as to form a real network: they are comparatively fewer in the ſucceeding branches, and become leſs frequent as we proceed towards the heart. Yet we ſtill find many even in the large branches, and in this reſpect the veins are particularly diſtinguiſhed from the arteries, the larger trunks of which are almoſt always iſolated. Theſe anaſtomoſes unite, in a very obvious manner, the cutaneous and the deep-ſeated veins: thus the ſinuſes of the cranium are connected, by means of the emiſſaria, with the temporal, occipital, and other external veins; the external and internal jugulars are joined together, under the angle of the jaw, by a large branch; the baſilic, cephalic, and their numerous diviſions ſpread over the forearm, to the brachial, radial, and ulnar, by ſeveral branches penetrating between the muſcles; and the ſaphenæ to the crural, tibial, and peroneal in a ſimilar manner. Thus the communications between the two great diviſions of the veins provide againſt interruption to the circulation from local preſſure. Thus we account for the encreaſed flow of blood in phlebotomy, produced by exerting the muſcles of the forearm; for the continuation of the circulation, when the ſuperficial veins are compreſſed by a ligature; and for the paſſage of anatomical injections from theſe into the deep-ſeated trunks. To theſe anaſtomoſes we are indebted, according to Bichat, for the power of following various faſhions in dreſs; the preſſure produced in the neck, at the hams and other parts, by different articles of clothing, would, he ſays, be very dangerous, if the ſuperficial veins could not empty themſelves into the more deeply ſeated trunks. If a ſingle vein be compreſſed, the blood paſſes readily into the neighbouring tubes; but when the preſſure is more general, it cauſes a retardation to the blood's paſſage in the capillary ſyſtem, and a general redneſs of the whole ſurface.

The anaſtomoſes take place nearly in the ſame manner as in the arteries: branches of equal ſize may communicate together; or ſmaller may be joined to larger ones. There may be ſimply a ſtraight communicating canal; or two branches may be joined by their extremities ſo as to form an arch; or there may be numerous communications between ſeveral branches, ſo as to form a plexus of veins. In general the anaſtamoſes are moſt numerous where the courſe of the blood is expoſed to the greateſt difficulty. Hence the frequent conjunctions of the ſpermatic veins, and the very intricate plexus formed in the bottom of the pelvis by the hypogaſtric veſſels. Yet theſe two parts of the venous ſyſtem are frequently the ſeats of varices; and few are found more frequently dilated in the dead body, on account of the great difficulty which the blood experiences in aſcending contrary to its own weight.

A comparative view of the courſe of the blood in the two ſyſtems will ſhew us, perhaps, that there are means of explaining why the communications are more frequent in the venous than in the arterial ſyſtem. The black blood is manifeſtly influenced by the force of gravitation on many occaſions. The erect attitude occaſions the veins of the lower parts to ſwell, particularly after diſeaſes which have produced debility: this ſwelling quickly diſappears if the legs are placed in an horizontal poſition, and increaſes if the perpendicular attitude be maintained. How conſiderably poſition affects various tumours and ulcers of the lower limbs is well known. A conſiderable ſwelling from difficulty in the return of the black blood is produced by what we call in common ſtanding on the head. Any kind of violent motion communicated to the black blood, independently of gravitation, will affect its courſe; and to this cauſe we may perhaps aſcribe the peculiar effect experienced on moving the body quickly in the circular direction. External and internal preſſure, and various mechanical

cauſes, are conſtantly influencing the courſe of the venous blood. The arterial blood is exempted from theſe cauſes of retardation, particularly from the action of gravity. The influence produced by the contraction of the heart deſtroys all effect of ſuch a cauſe.

The two venæ cavæ form two large venous cones; of which one, placed above the diaphragm, correſponds not only to the aſcending branches of the aorta, which ſupply the head, neck, and upper limbs, but alſo to the cheſt by the vena azygos: the other, ſituated below this muſcle, returns the blood carried out by the deſcending aorta, excepting that which goes in its intercoſtal branches. Although each of theſe veſſels forms a diſtinct cone, they communicate together, in the ſituation of their boundary, the diaphragm, by means of the azygos. This communicates below with the renal and lumbar veſſels, and opens above into the ſuperior cava; ſo that, if the inferior vena cava be obliterated, its blood can be conveyed, through the communications juſt mentioned, to the right auricle. Dr. Baillie has related a caſe of this kind in the "Tranſactions of a Society for the Promotion of Medical and Chirurgical Knowledge;" and the example is by no means a ſolitary one. When the blood takes this route, it paſſes, in ſome part of its courſe, contrary to its uſual direction. It goes from the trunk of the vena cava into the renal vein, and thence into the azygos; and this courſe is favoured by the abſence of valves from the parts juſt mentioned.

Organization of the vaſcular Syſtem of black Blood.—The muſcular fibres of the heart, and the fibrous coat of the pulmonary artery, which is exactly analogous to that of the aorta, will not be conſidered here: it is the ſtructure of the veins which we ſhall now examine.

After removing all the cellular covering of the vein, its proper coat (membrane propre of Bichat, membrana media of Haller) is brought into view. We now diſcern in the large trunks longitudinal fibres parallel to each other, forming a very thin layer, often difficultly perceptible at the firſt view, but always preſent. When the veſſels are conſiderably diſtended, theſe fibres are leſs manifeſt than in the contracted ſtate. Bichat finds them more numerous in the inferior than in the ſuperior cava; and in the ſuperficial, than in the deepſeated veins, as in the ſaphena compared to the crural. This anatomiſt alſo repreſents that they are more clearly marked in the branches than in the trunks, and that they are continued, at all diviſions, from one to the other: alſo that they are ſometimes condenſed, ſo as to give to the vein a conſiderable thickneſs. In general the venous fibre is remarkable for its tenacity, which greatly favours the extenſibility of the veins, and forms a ſtriking contraſt to the thickneſs of the arterial membrane. The ſtructure and properties of each order of veſſels are ſuited to the mode in which the blood circulates in them. The agent of impulſion at the commencement of the arteries requires in theſe tubes a firm and reſiſting ſtructure, while the ſlow movement of the venous blood is accommodated to the power of yielding in the ſides of the veins.

The fibres of the venous membrane ſeem not to have attracted the notice of phyſiologiſts in any great degree; Haller merely mentions them as "fibræ flexiles et rubræ, quæ venæ longitudinem ſequuntur;" and Soemmerring, who includes this with the cellular covering under the name of tunica extima, ſays of it, "fibroſi aliquid nonniſi in venis majoribus poteſt diſtingui." Bichat, from whom the deſcription is derived, ſays, that he conceives it to be of a peculiar nature, eſſentially different from all other tiſſues, and having its own organization and vital properties. He obſerves further, that they preſent very different appearances in different individuals, being ſometimes much more manifeſt than at others. They do not exiſt in the ſinuſes of the dura mater, which preſent merely ſeparations of that membrane, lined by a continuation of the common membrane of the veins:—conſequently the cellular covering, as well as the fibres, are abſent in the caſe of theſe veſſels. There is no appearance of circular fibres in any part of the veins.

The force with which the veins reſiſt any power tending to tear them is much greater than would be expected from their apparent tenacity. Their area is much larger in proportion to their ſides, than in the arteries; and the proportion, according to the experiments and calculations of Wintringham, which the thickneſs of the arterial coats bears to that of the veins, is as 15 to 1. This ſtatement, however, applies to the largeſt trunks, ſuch as the aorta and deſcending cava, and the ratio of the coats to the area of the veſſel increaſes as the veins become ſmaller. The ſpecific gravity of the veins exceeds that of the arteries in a ſmall degree.

As the denſity of the venous exceeds that of the arterial coats, their ſtrength is alſo ſuperior; that is, they bear greater diſtenſion without burſting. They yield more readily, and admit greater dilatation: the internal jugular vein may be diſtended with injection ſo as to form a very large cavity, and the minute veins admit injection ſo as to form extenſive networks, while the arteries would burſt under ſimilar force. Many examples ſhew us very conſiderable enlargements of the veins, when the ordinary courſe of circulation is obſtructed. Hales found the jugular vein bear a column of water of 175 feet, when the carotid was burſt by one of 190. Wintringham's experiments ſhew that the veins will bear even greater weights in this way than the arteries: the cava inferior ſuſtained 176 lb., and the aorta, in the ſame ſituation, 158 lb. 11 oz. The iliac vein was to the artery in this reſpect as 1034 to 1000. But in the veſſels of the viſcera, the arteries exceeded the veins, as the renal and ſplenic; and in an old dog the aorta was ſtronger than the cava. Still experience proves that in the living ſubject the veins are much more ſubject to dilatation and rupture than the arteries: varices and hemorrhoidal tumours are much more frequent than aneuriſms, and actual rupture is not a very unfrequent occurrence.

The common membrane of the black blood, extended from the general to the pulmonary capillary ſyſtem, is every where nearly of the ſame nature. It differs from that of the red blood by ſeveral characters. It admits of much greater diſtenſion, and is conſequently leſs brittle. Apply a ligature on a vein, and it will not cut through this coat, unleſs indeed the conſtriction ſhould be exceſſively tight; it is indeed nearly as pliant as the cellular covering, and can be diſſected much more eaſily than the correſponding membrane in the arterial ſyſtem. It is thinner, as we may ſee by obſerving the valves, which often eſcape obſervation on the firſt view from their great delicacy. Oſſification never takes place in it, and hence the tricuſpidal valve with the ſigmoid valves of the pulmonary artery and the lining of that veſſel, which are all formed by this membrane, never exhibit the bony depoſits which are ſo common in the correſponding parts of the other circulating ſyſtem.

This membrane is remarkable for forming a number of folds, called valves; the ſigmoid of the pulmonary artery, and the tricuſpidal are formed by it: but we ſhall here confine ourſelves to thoſe which are found in the veins carrying black blood. They are formed by the ſmooth inner membrane of the vein, produced from that part of the veſſel which is fartheſt from the heart, towards the heart, and into the

the cavity of the vein: in the latter ſituation they end by an extremely thin lunated margin, at which the membrane is reflected upon itſelf, and returns in a contrary direction to its commencement, to the lining of the vein. Thus two plates or laminæ are produced, exactly ſimilar to each other; an aſcending one from the lining of the vein to the lunated edge, and another deſcending from the latter to the former part. This deſcription, however, is in ſome degree imaginary; for the valves are ſo thin that they can hardly be ſplit into two plates. As the direction of branches, with reſpect to their trunks, varies, ſo the valves may differ in their poſition as compared to the heart; but in the above deſcription we ſuppoſe the veſſel to be going ſtraight to the heart. The extremities of the looſe edge, where they are connected to the ſides of the vein, are prolonged in a narrow form, ſo as to repreſent the two horns of a creſcent, theſe are called the cornua, and vary in length. Theſe folds are extremely thin, but ſtrong, and poſſeſs a ſomewhat ſhining appearance: according to Haller they often preſent foramina, and a reticulated appearance, as if they had given way to the force of the blood.

In every valve we diſtinguith the *fixed edge* by which the fold adheres to the lining of the vein, which is parabolical in its figure, and always turned from the heart; the *looſe edge*, floating in the cavity of the veſſel, lunated in its figure, prolonged into the cornua, and turned towards the heart; the *internal flat ſurface* which faces to the tube of the vein, and againſt which the blood tranſmitted through the veſſels paſſes; and the *external flat ſurface* turned towards the coats of the vein, and in contact with thoſe coats when the venous blood is flowing towards the heart in its natural direction. The two latter are continuous at the looſe edge. The margin adhering to the vein is ſtronger, and often hard or callous in its ſtructure; this is the *agger* of Morgagni; *le bourlet* of Senac. The figure of the valve, taken altogether, is that of a parabola, of which the convex apex is turned from the heart, and the ſides are continued along the tube of the vein towards that organ: hence, between the valve and the ſide of the veſſel a blind cavity is intercepted, called by ſome the *ſinus* of the valve, and repreſenting, when diſtended with wax, a parabolic cone, longer or ſhorter in different inſtances.

In the larger trunks theſe folds are generally arranged in pairs, as at the entrance of the internal jugular into the ſubclavian, in the large veins of the leg and arm, and the vena azygos. The two valves, compoſing the pair, are of equal ſize, and touch each other, at their looſe edges, when diſtended, ſo as to fill up the canal of the veſſel. It is uncommon to ſee three valves together; yet they are obſerved ſometimes in ſuch an arrangement, and completely meet in the canal of the vein, when raiſed, ſo as to cloſe it. Solitary valves are frequently found in the ſmaller veſſels, as in thoſe of the hand and foot: theſe are at the ſame time generally longer. Haller has ſeen ſuch in the ſpermatic and vena azygos, and ſays that they are ſometimes found in the extremities, and ſhut the whole canal of the vein when elevated. Branches ſometimes join venous trunks without any valves at their openings, and then there is a ſimple round opening with a ſharp edge, as at the origin of an arterial branch: in other inſtances there are valves juſt at the orifice, formed by the membrane of a branch.

The ſize of the valves is proportioned to that of the veſſel in which they are found; but they are not always ſufficiently large to cloſe it completely. This circumſtance, which has attracted the attention of moſt anatomiſts, who refer it to the original formation of the parts, is explained by Bichat by the varying ſtate of the calibre of the tube. When the vein is conſiderably dilated, the valves, which do not yield in the ſame proportion, are rendered ſmaller with reſpect to the enlarged canal, and do not, therefore, cloſe it completely: in the contracted condition of the part they are adequate to their original purpoſe. This circumſtance accounts for anatomical injections ſometimes finding their way, contrary to the courſe of the circulation, in theſe veſſels.

There are no valves from the auricle down to the iliac veins; none in the hepatic, renal, uterine, umbilical, cerebral, or coronary veins, excepting the ſingle one at the mouth of the coronary in the auricle. Some have deſcribed a valve at the opening of the ſpermatic into the renal vein. Haller has ſeen one or two valves, or pairs of valves, in the trunk of the vein, but not at its termination: this repreſentation is alſo ſupported by Monro, (De Semine et Teſtibus,) who has occaſionally found them more numerous in this veſſel. There are none in the ſmall veſſels over the whole body, in ſuch at leaſt, according to Haller, whoſe diameter is leſs than one line. Theſe folds begin in the iliac veins, where, however, they are not numerous. They are found in ſuch branches of the hypogaſtric veins as do not go to the uterus or bladder, and particularly in the veins of the penis and clitoris. Conſiderable numbers exiſt in the crural and popliteal: they are found at the opening of the ſaphena and of the ſaphena minor, and in their ramifications.

In deſcribing the ſituations, where valves are found in the branches of the ſuperior cava, we come firſt to the vena azygos, about which much controverſy has ariſen on this point. Fallopius and Euſtachius deny their exiſtence in this vein, and Haller aſſerts, as an excuſe for their error, that fluids, injected into the ſuperior cava, will always fill the trunk and branches of this veſſel. Various anatomiſts, as Riolan, Bartholin, Senac, and Morgagni, have deſcribed valves in different ſituations in this vein. Haller never ſaw any at its termination, nor in the intercoſtal veins; but always diſcovered ſome in the trunk, where it lies on the vertebræ. A large pair of valves is placed at the inferior end of the internal jugular vein; which, however, allow the paſſage of injection. In the ſinus of the poſterior valve, on the left ſide of the body, is the opening of the thoracic duct, furniſhed with a pair of valves, which prevent the blood from gaining admiſſion into that veſſel. Haller admits no other valves in the internal jugular vein; nor in the vertebral, nor the ſinuſes of the medulla ſpinalis. They are deſcribed in the external jugular, as alſo in conſiderable numbers in the branches which are ſent from the internal jugular to the face, tongue, and other parts on the outſide of the head. They are found in the ſubclavian trunk, and in the whole ſyſtem of the arm and forearm, where they are very numerous: hence the knotted appearance of theſe veins in injected preparations. Haller aſſigns four pairs to the trunk of the baſilic between the elbow and its termination, and the ſame number to the brachial vein in the ſame diſtance.

It appears, then, in general, that theſe folds are chiefly found in veins which have a perpendicular ſituation, as in the limbs, penis, teſticles, neck, and the vena azygos: alſo, that they are more numerous in the limbs, and in the cutaneous veſſels, and are hardly ever ſeen in the viſcera. Their exiſtence on the whole is conſtant, but their number and ſituation vary conſiderably. The moſt convenient mode of exhibiting them is by placing a vein, ſlit up, in water.

The effect of the valves, in preventing the blood from returning through the veins, in a courſe contrary to that of its natural current, is ſo obvious, that it need hardly be inſiſted on. Theſe thin folds lie cloſe to the ſide of the veſſel, and offer no obſtacle to the blood's courſe; but when that fluid is repelled in the vein, it lifts the looſe edge, enters the ſinus, and

and cauſes the margins of the two valves to approach ſo as to form a partition in the cavity of the veſſel. Hence the blood cannot retreat further than the ſituation of the firſt pair of valves; conſequently, any portion of a venous trunk has to ſuſtain only that quantity of blood, which is contained between the two pairs of valves which bound it. But for this arrangement the whole column of venous blood, when its return to the auricle was impeded, would have preſſed on the minute veins with a degree of force, which the coats of theſe veſſels could not have reſiſted. The neceſſity of ſuch a ſtructure ariſes out of the comparatively ſlow motion of the venous blood, the abſence of an impelling agent at its commencement, and the degree in which it is influenced by the force of gravitation.

In conſequence of theſe valves all preſſure muſt have the effect of ſending the blood on towards the heart: the valves prevent it from retreating, and there is conſequently but one direction in which the fluid, when urged by any external preſſure, can eſcape. Hence muſcular motion promotes the venous circulation.

The action of the valves can be well eſtimated by injections contrary to the blood's courſe: the elevation of the folds prevents the injected matter from paſſing the valve, and it diſtends the two ſinuſes ſo as terminate in two parabolical cones.

They enable us to diſpenſe with ligatures on the veins in moſt ſurgical operations, for no more blood can eſcape, than is contained between the opening and the firſt pair of valves.

The abſence of valves from the arteries proves, in the opinion of Bichat, that theſe veſſels have no active power of contraction. If they had, he ſays that valves would have been required to prevent the blood from being forced back. As the arteries recover themſelves by their organic contractility, which is exerted in a gentle manner, the valves at the mouth of the aorta are ſufficient to prevent the return of the blood towards the heart. There is the leſs need of valves in any other parts, becauſe the contraction of the arteries is conſequent on their containing leſs blood.

The effect of re-agents on the venous tiſſue preſents no very intereſting reſults. Theſe veſſels are pliant when dried: they reſiſt putrefaction and maceration leſs effectually than arteries, but more than moſt other tiſſues. Warm water or acids corrugate their coats, and render the fibres more ſenſible: this is the beſt method of obſerving them.

Veins poſſeſs in their coats arteries and veins, which do not differ eſſentially from thoſe of the arteries. Like the arteries alſo they are ſurrounded by two kinds of cellular ſubſtance: one of theſe is like that found in the intervals of all the organs, and ſerves to connect the veins to the ſurrounding parts; the other is denſe and cloſe in its ſtructure, and forms an external or cellular coat to the vein (celluloſa of Haller). This covering is very ſtrong, of a filamentous texture, and, although compoſed of cellular tiſſue, never contains any fat or ſerous fluid. It covers and includes the longitudinal fibres of the veins, according to the deſcription of Bichat, and is continued over to the ſurface of the common membrane. The [illegible] remarks alſo, that the preſence of cellular tubes, in the parietes of the veins is a diſtinctive character of theſe veſſels, decidedly ſeparating them from the arteries, to which indeed their tiſſue is not at all analogous.

There is no reaſon to ſuppoſe that abſorption or exhalation are carried on at the internal ſurfaces of veins. Bichat performed ſimilar experiments on theſe veſſels to thoſe which are mentioned concerning the arteries, and with the ſame reſult. If there were any ſecretion from the common membrane, a vein would not become obliterated as it does, when blood no longers paſſes through it. The exhalants and abſorbents of veins are therefore confined to the office of nutrition, and conſequently are few in number.

There are very few nerves from the ganglia obſerved on the veins, while they are ſo numerous, in many parts of the arterial ſyſtem, as to form almoſt an acceſſory covering. Yet the right ſide of the heart ſeems to poſſeſs as large a ſupply of theſe organs as the left. The pulmonary artery has very few nerves. Hence, in a general view of the matter, the ſyſtem of red blood has obviouſly a much larger ſhare of nerves than that of black.

Properties of the vaſcular Syſtem of red Blood.—The veins have very little elaſticity, are ſoft and lax in their texture.

Extenſibility.—They poſſeſs but little of this property in the longitudinal direction: but enjoy it in a very high degree in the direction of their diameter. They may be diſtended enormouſly in the dead ſubject by injections; and undergo very great enlargement, when they form varices, in the living ſtate. Arteries can hardly be ſtretched to twice their natural diameter without burſting their internal lining, while veins may be extended to three, four, or even five times their original ſize. Yet, as we have already obſerved, there are frequent examples of their rupture during life; as of thoſe in the lower extremity, during pregnancy, in the hemorrhoidal and cerebral veſſels, &c. The venæ cavæ, ſubclavian, and jugular veins have burſt ſuddenly, without any apparent diſeaſe. Poſſibly the different courſe of the fibres may account for the veins being moſt extenſible in a direction oppoſite to that of the arteries.

The *contractility* correſponds in degree and direction to the former property. It cauſes the parietes of the umbilical vein, or of any trunk, when tied, to contract and obliterate the veſſel; and occaſions the ſudden evacuation of the blood contained between two ligatures, when the veſſel is punctured. The innumerable varieties of calibre, dependant on the quantity of contained blood, which the veins preſent both in the dead and living body, ariſe from their extenſibility and contractility. In what different ſtates are the ſuperficial veins ſeen; dilated in ſummer, in the warm bath, and in the perpendicular poſition of the limbs; contracted in winter, in the cold bath, and in the horizontal ſtate of the extremities. "I doubt," ſays Bichat, "whether thoſe who have favoured the world with ſo many calculations of the capacity of the veſſels, the velocity of the blood, &c. would have undertaken theſe labours if they had opened many bodies, or diſſected many living animals."

Vital Properties. Animal Senſibiltty?—Mechanical irritation of the external or internal ſurface, the application of ligatures, and the injection of irritating ſubſtances, as urine, bile, wine, narcotics, &c. produce no marks of pain. The introduction of air is ſpeedily, but not inſtantaneouſly followed by piercing cries and violent convulſive motions. It may be doubted whether this ariſes from any effects produced upon the veins. The ſame proofs which are mentioned concerning the arteries, demonſtrate that the veins poſſeſs no animal contractility.

Properties of the organic Life. Senſible Contractility?—No kind of irritation produces any diſcernible contraction in the veins; ſuch was the reſult of Haller's experiments, which have been confirmed by the ſubſequent trials of Bichat. The venæ cavæ, near the auricle, poſſeſs obviouſly muſcular fibres, continuous with thoſe of the heart; and here therefore the power of contraction is not doubted. Neither the arteries nor veins ever preſent, in diſeaſes, thoſe phenomena produced by the augmented energy of contractile power, which are exhibited by organs, in which this power exiſts evidently in a natural ſtate. The kind of beating, ſometimes obſerved in the large veins near the heart, muſt not be miſtaken

miſtaken for the effect of irritability. This phenomenon is produced merely by the reflux of the blood, which not being able to paſs through the lungs, is accumulated in the pulmonary artery and right ſide of the heart; hence, when the latter contracts, as it finds an obſtacle to the propulſion of its contents in the ordinary courſe, the blood is urged back again. This reflux takes place to a certain diſtance, in ſpite of the valves; and is very perceptible, on many occaſions, in the jugular veins, when animals ſubmitted to experiments reſpire laborioufly. It is alſo ſeen in the laſt moments of life, when the pulmonary circulation begins to be troubled. The cauſe of dilatation ceaſing, the contractility of the veins reduces the veſſel to its former ſtate.

This reflux of the black blood takes place, in a ſlight degree, in the natural actions of the parts. As the openings of the veins are free, the contraction of the auricle muſt repel the contained fluid to a certain extent.

Inſenſible contractility, and its inſeparable concomitant, organic ſenſibility, exiſts in the veins as in other parts of the body, and is concerned merely with the buſineſs of nutrition. It is more ſtrongly marked than in the arteries; at leaſt the diſeaſes, which particularly increaſe its energy, are more frequent in the veins. The latter veſſels are more readily inflamed, in conſequence of injuries, and their wounds, as in phlebotomy, heal more rapidly.

Bichat gives us the following account of the motion of the black blood in the veins. "It appears from what has been already ſaid, and what is ſtated of the capillary ſyſtem, that the blood, when it has arrived in the veins, is no longer influenced by the heart's action; conſequently theſe veſſels can have no pulſation. As there is no agent of impulſion in this ſyſtem, the cauſe determining the pulſe does not exiſt. The conditions neceſſary to its production, in the organization of the veſſel, as elaſticity and reſiſtance, do not exiſt in the veins. They admit therefore only the reflux produced under certain diſordered ſtates of the circulation; or the undulation cauſed by making arterial blood circulate in them in experiments; and in both theſe caſes the effect is produced by the heart.

"The blood moves through the veins in the following manner. The capillary ſyſtem, by its inſenſible contraction, is conſtantly pouring into the veins a certain quantity of blood. A general movement is communicated by this newly arrived portion to the former contents of the veſſels; and the addition at one end, as the ſyſtem is always full, renders it neceſſary that ſome ſhould eſcape at the other, or elſe the venous parietes would be dilated. Now, as theſe poſſeſs ſome power of reſiſtance, the blood flows on to the heart.

"However, the impulſe produced by the inſenſible contraction of the capillary ſyſtem, is too weak to extend inſtantaneouſly from one end of the veins to the other, particularly where the fluid is obliged to move in a direction contrary to the force of gravity. The weight of the column would produce a retardation, and conſequent dilatation of all the veins, if this effect were not obviated by the valves. The exiſtence of theſe folds is a neceſſary conſequence of the weakneſs of the veins. If the veins had been as unyielding as the arteries, they would neceſſarily tranſmit a portion of blood to the heart, whenever a new quantity enters the ſyſtem, although they ſhould poſſeſs no valves.

"As the impulſe communicated to the blood does not much exceed the reſiſtance which it meets with, a very ſlight cauſe will diſturb its motion. Hence the neceſſity of anaſtomoſes; and hence too the acceſſory circumſtances which aſſiſt this motion. Under this head the following are enumerated. 1ſt. The action of muſcles; of which the influence is clearly proved by the acceleration of the jet in phlebotomy, when the muſcles are exerted. In confirmation of this ſtatement we may adduce the abſence of varices from the deepſeated, and their frequency in the cutaneous veins. 2dly. The pulſation of arteries has been ſuppoſed to accelerate the blood's motion in the contiguous veins; but this appears to us more than doubtful. 3dly. The motions of various organs, as of the brain, abdominal and thoracic viſcera, have been conſidered to produce an accelerating effect; but we do not deem this to be very clearly proved. 4thly. Friction of the ſurface. 5thly. Slight compreſſion unqueſtionably favours the return of the venous blood; as is ſhewn in the ſurgical employment of bandages in ulcers and varices of the legs.

"As the ſource of the blood's motion in the veins is placed in the general capillary ſyſtem, inſtead of being concentrated in a ſingle organ, it may vary according to the ſtate of the capillaries in various parts, as obſervation will eaſily prove to us, whereas, in the arteries, the motion is uniform in all parts.

"In general, the motion of the blood in the veins requires many reſearches for its elucidation; the ſubject is involved in an obſcurity through which we can ſcarcely diſcern a few rays of light. The cauſe of this is, that we do not know the kind and degree of motion communicated to the blood in the capillary ſyſtem, the influence of the vaſcular parietes, &c. Our knowledge conſiſts merely of a few ſeparate views, tending more particularly to ſhew the contraſt between the circulation in the veins and in the arteries. A parallel of the two circulations may aſſiſt in elucidating that of the veins, and we therefore give a ſhort general ſtatement of it. 1ſt. General pulſation in the arteries; abſence of this in the veins. 2dly. Rapid courſe of the blood in the former, and ſlow progreſs in the latter. 3dly. Greater capacity and thinner ſides in the veins; leſs capacity and thicker coats in the arteries. 4thly. Neceſſity of acceſſory aſſiſtance in the veins; inutility of this in the arterial circulation. 5thly. Projection of blood by ſucceſſive jerks in the latter; uniform ſtream in the former. 6thly. The circulation influenced by gravity and other extraneous circumſtances in the veins; and exempt from ſuch influence in the arteries. Such is the ſeries of phenomena, which appear to depend on the exiſtence of an impelling agent at the origin of the arteries, and its abſence in the veins. From the unity of the impulſe in the former, and its varieties in the latter ſyſtem, ariſe, 1ſt, conſtant uniformity of motion in all the arteries; varieties in the movement in each part of the venous ſyſtem; 2dly, general ſameneſs in the degree of dilatation or contraction in all the arteries of the dead ſubject; great variety in the veins of different parts.

"To illuſtrate the different motions of the arterial and venous blood, ſome authors have inſiſted much on this point: that in the arteries the blood is urged through tubes conſtantly decreaſing to the capillary ſyſtem, which reſiſts; while in the veins it flows in canals, always increaſing to the right auricle, which offers no reſiſtance. But the black blood of the abdomen moves through decreaſing tubes to the capillaries of the liver, and its motion ſeems exactly ſimilar to that in the general veins."

The ſympathies of the veins, like thoſe of the arteries, are very obſcure. As the tiſſues of theſe veſſels are ſeldom morbidly affected, as inflammation and pain but ſeldom occur in them, we know hardly any thing of the effects which they produce on other organs. When the experiment of tranſfuſion was frequently practiſed, acrid and irritating matters introduced into the veins often produced ſudden convulſions in different muſcles. The influence of other organs on the veins is as little known; ſince theſe veſſels are generally diſſeminated, as well as the arteries and nerves, it is difficult to decide whether

whether any ſympathetic phenomenon takes place in the vein or in the organ to which the veſſel belongs.

Progreſſive Developement of the circulating Syſtem containing black Blood.—Contrary to what we have pointed out in the arteries, the veins in the fœtus are proportionally leſs developed than in the adult. To obſerve this fact, we muſt not ſelect the large trunks of the cavæ, ſubclavian, &c. becauſe they are commonly diſtended at the moment of death, ſo as to appear much larger than is natural to them: it is in the branches and ſmaller ſubdiviſions that we find the diſproportion alluded to. Yet the right ſide of the heart does not partake this character with the reſt of the ſyſtem; on the contrary, as it receives the blood of the umbilical vein it is larger than the left. The ſmaller proportional ſize of the veins, at the period alluded to, ariſes from the rapidity of nutrition, which diſpoſes of much matter in the growth of the body, ſo that there is leſs to be ſent back again through the veins. As the growth is leſs rapid towards the time of birth, the veins approach to the relative magnitude, which they exhibit in the adult. The venous fibres cannot be diſtinguiſhed at this time; yet their organization is as ſtrong, and affords as much reſiſtance to any dilating power as after birth.

The remarkable revolution at the time of birth, which has been already noticed, occaſions the whole of the blood, which before had partly paſſed to the left cavities of the heart, through the foramen ovale, to remain on the right ſide. During the firſt years of life, the veins ſtill preſerve their relative inferiority to the arteries; and this character ſubſiſts during the whole period of growth. An examination of the cutaneous veins will ſuffice to prove the fact; they are never ſo ſtrongly marked in the infant as in the adult, as a view of the arm of a child compared to that of a man will clearly ſhew at the epocha of puberty. When the growth of the body in length is completed, the veins partake of the general plethora, which characterizes that age. When the increaſe of the body, both in length and ſize, is finiſhed, theſe veſſels become larger, and are conſequently more prominent. The application of a ligature or ſtrong contractions of the muſcles of a limb in a youth and a full-grown man will ſhew this difference.

In old age the veins become very large as compared with their condition in the early periods of exiſtence: ſo that the two extremes of life, preſent in this point an inverſe diſpoſition. Theſe veſſels are more ſenſible on the ſurface of the body; but their ſides are not increaſed in thickneſs. The movement of decompoſition predominates over that of compoſition at this age; and more ſubſtance is carried away from the organs than is added to them. However, the ſlowneſs of the circulation in the veins, by producing dilatation of theſe canals, may have a ſhare in producing this apparent ſuperabundance of black blood, and thus exemplifies a poſition, which has been already ſtated, *viz.* that the capacity of theſe veſſels is in an inverſe ratio to the velocity of the blood's motion in them. Thus the velocity is ſmall and the capacity great in old age, while the oppoſite condition prevails in infancy.

The veins of the lower parts are more dilated in old age than thoſe of the upper; on account of the habitual unfavourable influence of the poſition of the parts. Since the influence producing motion is comparatively weak in this ſyſtem, mechanical cauſes have conſiderable power over the venous circulation: hence the frequency of varices in the lower, and their almoſt entire abſence from the upper parts of the body. Hardly any women, who have had many children, are entirely free from theſe ſwellings. Varices are the common complaint of old age, while aneuriſms are rare: the rupture of the veins, too, has commonly taken place at this or the adult age, but not in infants.

The pulmonary artery of the old ſubject does not undergo a dilatation analogous to that of the veins, with which it forms one ſyſtem. Removed from the operation of external agents, furniſhed at its commencement with a muſcular impelling organ, and formed of a firm and reſiſting tiſſue, it is not expoſed to the cauſes of dilatation.

Two kinds of accidental developement of the venous ſyſtem may be obſerved: 1ſt, in various tumours, which receive a large quantity of venous blood, and from which there muſt be a correſponding quantity of black blood returned. The enlarged ſuperficial veins form a ſtriking character of ſuch ſwellings. 2dly. The veins may be dilated, where the return of blood is obſtructed; as in the diſtended abdominal parietes of a dropſical perſon.

Remarks on the Pulmonary Veſſels.—The pulmonary artery, which is repreſented in the foregoing account as forming part of the ſyſtem of black blood; and the veins which are deſcribed to belong to that of the red blood, belong to thoſe two ſyſtems reſpectively, only inaſmuch as they are lined by the common membranes, of which the nature is the ſame throughout all parts of each ſyſtem. But the tiſſue of the pulmonary artery, although added to the membrane of black blood, is juſt the ſame with that of the aorta and its diviſions, excepting a ſlight difference in thickneſs: and that of the pulmonary veins, although covering the membrane of red blood, correſponds in like manner to that of the general veins. Theſe reſemblances of ſtructure lead to ſimilarity in functions; accordingly, the mechanical laws of the circulation of black blood are the ſame in the pulmonary artery as thoſe of the red are in the aorta; and thoſe which regulate the circulation of the black blood in the general veins, preſide over the motion of the red in the pulmonary veins.

There are ſome modifications dependent on local cauſes; thus, on account of the ſhort courſe deſcribed by the pulmonary veins, gravity has no influence on their blood, and they never become varicous.

The ſame general diſpoſitions are obſerved in the arteries and veins, whether they are ſubſervient to the circulation of red or of black blood. Each artery has a ſingle orifice, neceſſary to the unity of impulſion, and of the blood's courſe in the great veſſels: the veins open by ſeveral iſolated mouths, as the motion of their fluid is not uniform in all parts of their ſyſtem, but may experience local acceleration or retardment.

Abdominal Syſtem of black Blood.—The abdomen contains a ſyſtem of veſſels, in which black blood circulates, abſolutely independent of the preceding, called the vena portarum, and found in moſt animals. It ariſes in that diviſion of the general capillary ſyſtem, which belongs to the ſtomach, inteſtines, omentum, ſpleen, pancreas, in a word to all the abdominal viſcera, which are concerned in digeſtion. Thoſe viſcera contained in this cavity, which have no ſhare in the digeſtive proceſs, as the kidnies and generative organs, &c. ſend their black blood into the general ſyſtem. Ariſing thus from the digeſtive apparatus, this ſyſtem forms two or three trunks, which are ſpeedily united into one, which comes to the under ſurface of the liver. There it branches out again into an infinity of ramifications, which are loſt in the tiſſue of the organ. Thus we have the ſame general diſpoſition as in the preceding ſyſtems;—two trees, of which the trunks are united. Place a muſcular organ at the union of the trunks, and the arrangement will be exactly the ſame. The union of the veſſels in the abdominal portion of this ſyſtem is performed in the ſame manner as in the general

neral veins; and their ſubdiviſions in the liver offer no peculiarities, except that they do not anaſtomoſe. The circumſtances of their diſtribution in the liver remove all thoſe cauſes of retardation and obſtruction, which affect the courſe of the venous blood in the general ſyſtem. Hence there is no neceſſity for anaſtomoſes, as in the lungs, ſpleen, kidney, &c. In the hepatic portion of the ſyſtem the communications are large and numerous, as the courſe of the blood is expoſed here to frequent cauſes of obſtruction. The circulation is carried on in theſe veſſels, as in the veins, and is conſequently equally expoſed to diſturbing influences. The effect of gravity is as ſtrongly marked here as in the former ſyſtem; and the hemorrhoidal veins, which, by their poſition are moſt expoſed to this influence, are the moſt frequently varicous.

Whether this ſyſtem communicates with the former, in its minute branches, is not yet aſcertained.

Many authors, and particularly Haller, conſidering that this ſyſtem has no agent of impulſion, have aſcribed to the veſſels a ſuperior degree of ſtrength; but the ſtructure in reality appears the ſame. The exiſtence of fibres is dubious. In the hepatic part of the veſſels there is a greater abundance of cellular tiſſue externally.

The analogy of ſtructure in the abdominal and general ſyſtems of black blood, leads us naturally to expect a correſponding reſemblance in their vital properties, ſympathies, &c. Irritation of the meſenteric veins has preciſely the ſame effects as that of any others in the general ſyſtem. The common membrane of the vena portarum is every where deſtitute of valves. As the courſe of the blood is ſo much ſhorter in this inſtance, there is the leſs need of providing the ſupports furniſhed by thoſe folds: and the abſence of an organ of impulſion is attended with a want of the reflux obſerved in the other veins, ſo that the fluid runs always uniformly in this ſyſtem from one ſet of capillaries to the other, without any retrograde paſſage.

"This uniformity," ſays Bichat, "depends alſo in part on another circumſtance; *viz.* that the liver preſents to the blood's motion none of thoſe obſtacles which occur ſo frequently in the lungs. The former organ, compoſed of a firm tiſſue, admits only of a general locomotion; and is therefore inſuſceptible of that dilatation and contraction of its individual component parts, which affect ſo conſiderably the paſſage of the blood through the lungs. From the foregoing peculiarities we underſtand; 1ſt, why, when the abdomen is opened in a living animal, no reflux is obſerved in the veins of the abdominal ſyſtem; 2dly, why the quantity of blood is nearly uniform in this ſyſtem, and conſequently, why the dimenſions of the trunk and branches do not exhibit thoſe numerous varieties in ſize obſerved in the other ſyſtem; and, 3dly, why the volume of the liver varies very little after death. The bulk of the lung is very different in different bodies, and its ſpecific gravity is greater or leſs according as its veſſels are more or leſs diſtended with venous blood: it preſents the two oppoſite extremes in the deaths by aſphyxia and hæmorrhage. Whatever the kind of death may have been, the hepatic part of the vena portarum contains the ſame proportion of blood. However, the ſyſtem of the hepatic veins varies conſiderably in this reſpect, and that part of the liver conſequently may be more or leſs gorged with blood, according as the paſſage through the lungs has been leſs or more free.

The mechaniſm of the circulation in the abdominal portion of this ſyſtem is exactly the ſame as in the general veins: but that of the hepatic part is unique in the animal economy. It bears no analogy to the courſe of the blood in the arteries, where the action of the heart produces the whole effect. There is much obſcurity in this ſubject, as well as in the courſe of the blood in the general veins, and every judicious mind cannot fail to obſerve that there is a great vacuum to be filled up in both caſes.

In the abdominal, as in the general venous ſyſtem, external forces produce conſiderable effect. The motions of the reſpiratory muſcles, the dilatation and contraction of the hollow viſcera, the locomotion of the moveable abdominal contents, muſt influence the circulation in the vena portarum: and probably the abſence of theſe contributes, with their perpendicular poſition, to retard the blood's courſe in the hemorrhoidal veins, and thereby to occaſion varices. Yet the extent of this influence is exaggerated by Boerhaave, when he repreſents that the circulation cannot be carried on without it. In fact, the blood is ſtill tranſmitted to the liver, when the abdomen is laid open in a living animal; but this circulation is ſenſibly weakened in a ſhort time, before the general is even languid."

The abdominal ſyſtem of black blood is not iſolated in the fœtus; it forms one with the two others, through the communication of the canalis venoſus: hence the fœtus has a ſingle vaſcular ſyſtem, while the infant which has breathed poſſeſſes three ſeparate ſyſtems, two of black and one of red blood. The mode, in which the two ſyſtems communicate in the liver of the fœtus, had been already deſcribed in the article EMBRYO. The abdominal vaſcular ſyſtem is leſs developed at this time, than in the ſequel; yet the liver is much larger on account of the blood, which arrives at it from the placenta through the umbilical vein. The exceſs of ſize in the liver is the more ſtrongly marked, in proportion as the fœtus is younger; and this predominance, according to Portal, continues till the ſeventh month. As the blood brought by the umbilical vein and that of the vena portarum are evidently mixed, at leaſt in great part, a queſtion ariſes whether they are of the ſame nature; and on this ſubject we have no data to form a judgment. At the time of birth, the ſupply of blood from the umbilical vein is cut off, and the liver is the end of the abdominal black blood only. The canalis venoſus becomes cloſed in conſequence of its organic contractility. The differences produced in the hepatic circulation at the time of birth are; 1ſt, that leſs blood, and that of one kind only, arrives at the liver: 2dly, that all communication between the abdominal and general ſyſtems of black blood is cut off: 3dly, that the proportional bulk of the liver is diminiſhed. Thus the latter organ experiences changes at this time, which are exactly the inverſe of thoſe that occur in the lung. During the age of youth, the abdominal ſyſtem, like the general, is not in a ſtate of great activity; it is called into greater exertion towards the interval between the thirtieth and fortieth years. That is the age of gaſtric diſeaſes, of hemorrhoids, and of hypochondriac affections, which are cloſely connected with the ſtate of the liver. It is not dilated in old age, like the preceding ſyſtem; nor does it ever exhibit bony depoſitions.

Of the Capillary Syſtems.—It muſt appear evident, from the preceding deſcription, that there are two of theſe, perfectly diſtinct from each other. One, generally diſperſed over the whole body, contained in all the viſcera and organs of every deſcription, is the ſeat of the change of the blood from red to black; while, in the other, which is concentrated in the lungs, the blood is again converted from black to red. The circumſtances, which particularly deſerve our notice in the capillary ſyſtem, are, 1ſt, that the circulation in them is regulated by peculiar laws; 2dly, that moſt of the important functions of the organic life, ſuch as ſecretion, nutrition, exhalation, &c. take place in them; 3dly, that ther

they are the ſeat of diſeaſes; and 4thly, that animal heat is produced in them.

The general capillary ſyſtem exiſts in all the organs of the body, which in fact are compoſed of a vaſt number of ſuch tubes, divided, united, &c. in a thouſand ways. The larger arteries and veins, lodged in the intervals of the component parts of organs, are foreign to their interior ſtructure, while the capillaries are an eſſential component part of the organ and belong to its tiſſue. In this point of view the body may be regarded as an aſſemblage of veſſels. Hence, the extent of the general capillary ſyſtem muſt be immenſe; it embraces all the ſmalleſt diviſions of our organs, ſo that we can ſcarcely conceive any organic molecules united without capillaries. It is not, therefore, merely ſomething intermediate between the arteries and veins; it gives origin to the exhalants, the excretory tubes, and the veſſels which convey the materials of nutrition. Other fluids beſides the blood circulate in it: many parts of the animal economy poſſeſs only colourleſs fluids. In the muſcular ſyſtem, in the ſpleen, in certain parts of the mucous ſyſtem, as the pituitary membrane, &c. the blood predominates ſo conſiderably in the capillaries, that they ſeem hardly to admit any thing elſe. Hence, arteries and veins are ſeen in great abundance, and the moſt minute injections diſcover no other veſſels. Moſt parts of the animal economy, ſuch as the bones, cellular ſubſtance, ſerous membranes, part of the fibrous ſyſtem, the ſkin, blood-veſſels, glands, &c. have in their capillaries both blood and other fluids.

Expoſe a ſerous membrane in a living animal; its tranſparence will enable you to obſerve, that the capillaries contain very little blood, and the white or greyiſh colour of the part ſeems obviouſly to depend on this circumſtance. After obſerving the quantity of blood contained in the part in its natural ſtate, irritate it by any kind of ſtimulant; it will then become covered by an infinite number of reddiſh ſtreaks, which convert its whiteneſs into the red colour of the mucous ſurfaces. Fine injections in the dead body will penetrate into the capillary ſyſtem of a ſerous membrane, as the peritoneum for example, ſo as to make it ſeem compoſed of an intertexture of veſſels, although very few contain blood in the living ſtate. All the organs juſt enumerated diſplay analogous phenomena: the ſkin, when well injected, is rendered intenſely red; and numerous veſſels are diſtended with blood in bluſhing, which were not before apparent. The progreſs of inflammation in the conjunctiva is another good example. Cellular ſubſtance, when irritated, and conſequently inflamed, in a living animal, or minutely injected, exhibits ſimilar appearances.

The proportions between the blood and the other fluids vary greatly; very little of the former is contained in ſerous membranes; more is ſeen in the ſkin, and a ſtill greater proportion in mucous membranes.

No blood is contained in the capillaries of the tendons, cartilages, hair, certain ligaments, &c. Theſe organs, diſſected in a living animal, do not pour forth a ſingle drop of blood: yet very fine injections will ſometimes ſhew that they contain capillary veſſels, which are alſo demonſtrated by inflammation.

The number of capillaries, as ſhewn by injections, ſeems to be very different in different organs. Bichat explains the difference by obſerving, that organs, in which injections exhibit but few of theſe veſſels, have the buſineſs of nutrition only carried on in them, as the bones, muſcles, cartilages, fibrous ſyſtem, &c.; while in parts, penetrated by greater abundance of fluids, other functions, ſuch as exhalation and ſecretion, are performed in addition to nutrition. The capillary ſyſtem, therefore, of organs is not in proportion to their maſſes; a ſlip of pleura contains more veſſels than a tendon of ten times the bulk.

It muſt be evident from theſe remarks, that fine injections, which are uſeful in ſhewing the capillary ſyſtem of an organ, cannot be depended on for teaching us where blood is contained, and where other fluids circulate. We can acquire this knowledge only by the obſervation of living animals, and by comparing what we ſee in them with the reſult of injections. The latter are alſo uſeful in learning the anatomy of the larger veſſels. In organs, which partly contain blood, and partly other fluids, the proportion of the former to the latter varies infinitely. Numerous cauſes, both in the healthy ſtate, and in that of diſeaſe, by attracting more or leſs fluids towards the organ, may fill its capillaries in various degrees. The whole exterior of the ſkin may exhibit phenomena analogous to that of bluſhing already mentioned. The ſerous and mucous membranes are found in very different ſtates, &c.; yet Bichat makes a diſtinction in this ſubject. An increaſed afflux of blood in the glands occurs only where abundant ſecretion depends on increaſed energy of the vital powers: when, on the contrary, it ariſes from deficient vital force, the gland does not contain a greater quantity of blood. The ſame remark applies alſo to the exhalations. Thus, in a feveriſh attack, more blood is ſent to the ſkin; but when ſweats ariſe from weakneſs, as in phthiſis, this accumulation of blood does not occur. He divides ſecretions and exhalations into active and paſſive; the former are preceded and accompanied by a manifeſt developement of the vital powers, and the latter by an oppoſite condition. Active ſecretions and exhalations are preceded by a more abundant afflux of blood to the part; while thoſe of the paſſive kind are performed in an oppoſite ſtate of the veſſels.

A perfectly free communication exiſts in all parts of the capillary ſyſtem. Obſerve a well injected ſerous membrane; its capillaries form a very minute net-work, in which no vaſcular thread is continued for more than two lines without communicating with the neighbouring ones. Hence the paſſage is conſtantly open, from the part which receives blood, to that which admits other fluids. Organs containing only colourleſs fluids, evidently communicate with thoſe neighbouring parts which admit blood. Hence we muſt regard the capillary ſyſtem as a general net-work, extended over the whole body, communicating throughout each organ, and alſo from one organ to another, ſo that there is a general anaſtomoſis or free communication of the fluids from the head to the feet; and it is in this ſenſe only, that we can form any rational notion of the general permeability of the frame. As the arteries, veins, exhalants, and excretories are all connected to the capillary ſyſtem, all theſe veſſels muſt communicate, ſo that a thin fluid, injected by the firſt, will paſs out at the two latter, and return by the veins after going through the capillaries. Thus an infinite number of paſſages are conſtantly open to the blood: of paſſages opening every where externally, and preſenting no mechanical obſtacles to the blood, which is retained within the limits of the circulation by the vital powers only. Fine injections will exude, in the dead ſubject, on the ſerous and mucous membranes, and even on the ſkin, on the urinary, pancreatic, biliary, ſalivary paſſages, &c.; and even coarſer fluids thrown into the arteries will often return by the veins.

Thus the capillary ſyſtem may be conceived to repreſent a kind of general reſervoir, at which the arteries arrive on one ſide, and from which depart, on the other, the nutritive exhalants in all organs, ſome other peculiar ones in certain parts, as thoſe which ſeparate the ſweat, lymph, fat, &c., and in others the ſecretory veſſels. The red blood enters on

on one ſide; the black blood, exhalations, ſecretions, &c., are ſent out on the oppoſite.

The general communications of the capillaries explain the colour of parts of the body produced by its poſition after death, and the diſappearance of redneſs from inflamed parts, in conſequence of the blood retained in them by the vital powers, being afterwards actuated merely by phyſical impulſes.

Under the circumſtances of ſuch free communication, as we have already pointed out, how does it happen that blood does not enter into the veſſels conveying other fluids, and *vice verſa?* that it does not paſs out through the exhalants and excretories? This ſeems to depend ſimply on the relation that ſubſiſts between the organic ſenſibility of each part of the capillary ſyſtem, and the fluid which it contains. Why do the lacteals ſelect a particular matter from what comes in contact with them? and why ſhould the ſkin abſorb certain ſubſtances, and reject others? All theſe phenomena depend on the general fact, that each part, each portion of an organ, each organized molecule, has its own mode of ſenſibility, which is in uniſon with one ſubſtance, and rejects all others. But as this may vary, the relation between any organ, and ſubſtances foreign to it, is liable to correſponding changes: thus a part of the capillary ſyſtem, which rejected the blood, admits that fluid when its ſenſibility has been exalted.

A ſeries of organized tubes is regulated by very different laws, from thoſe which govern an aſſemblage of inert pipes. In the latter, mechanical obſtacles only can prevent the communication of fluids. In the living economy, on the contrary, the peculiar vital powers of each canal form the obſtacle, by which the various fluids are limited. "Thus," ſays Bichat, "every organized veſſel is really active: it admits or rejects the fluids which enter according as it is able or not to ſupport their preſſure. Diſproportion of capacity is altogether foreign to this phenomenon; and the veſſel refuſes to admit the fluid merely becauſe it is heterogeneous to its ſenſibility." In this point the theory of Boerhaave was ſtrikingly defective. When this phyſician wrote, the vital powers had not been analized: phyſical forces were reſorted to for the explanation of vital phenomena, and we cannot be ſurpriſed at the weakneſs of his theories. In fact, explanations of living functions, borrowed from the phyſical forces, are as inadequate to their ſolution, as theories drawn from the laws of vital actions would be to the inveſtigation of phyſical phenomena. Would you not laugh at a perſon, who ſhould attempt to explain the motions of the planets, or of rivers, by irritability and ſenſibility? laugh then at thoſe who employ gravity, impulſe, &c., in developing the actions of the animal powers. The phyſical ſciences have made a remarkable progreſs only ſince the ſimple laws, which preſide over their innumerable phenomena, have been analized. In the ſame way, the explanations employed in phyſiology have reſted on a ſolid foundation only ſince the vital laws have been developed, and acknowledged as the ſource of the phenomena in all inſtances. How eaſily are the ſecretions, exhalations, abſorptions, inflammation, capillary circulation, &c., connected to the ſame principles, and derived from the ſame data, when they are all referred to their real cauſe, *viz.* the various modifications of ſenſibility in the organs which execute them. On the contrary, each preſented a new difficulty, when mechanical cauſes alone were adopted for their explanation.

"From what has been ſtated above it follows, that the innumerable variations, in the fluids of the capillary ſyſtem, are preceded and determined by changes of ſenſibility in the vaſcular parietes. Such alterations are not effected in the larger arterial and venous ramifications, where the fluids are in too large maſſes, and too powerfully impelled to be thus immediately influenced by the ſides of the veſſels.

"Although the organic arrangement be the ſame in the living and in the dead ſubject, the paſſage of fluids through the capillary ſyſtem is very different in the two caſes. Place a tube in the aorta of an animal, which we may kill by opening that veſſel, and immediately throw in any animal fluid; you will never find it fill the capillary ſyſtem, and exude through the exhalants, excretories, &c., as it will do when the ſubject has been ſome time dead. The inherent organic ſenſibility of the parts repels the injection, which can penetrate into the larger veſſels only. This experiment I have performed repeatedly without ever ſucceeding in filling the capillaries.

"Buniva has made comparative experiments on injections in living and dead animals with the ſame refults."

The capillary veſſels are ſo ſmall, that we cannot pretend to poſſeſs any data concerning their ſtructure, founded on actual examination of the individual tubes. Very probably this ſtructure is differently modified in each organ, ſo as to partake of the diſtinctive characters of the part: probably too, the lining of theſe veſſels is of a ſimilar nature to that of the continuous arteries, veins, and exhalants. Moſt likely the various organizations of the capillaries eſſentially influence the differences obſerved in the vital properties, that is, in the organic ſenſibility and the organic inſenſible contractility of each ſyſtem: hence the particular modifications of the diſeaſes dependent on theſe properties, and particularly reſiding in the capillaries, ſuch as inflammations, tumours, hæmorrhage, &c. The diverſities of ſtructure in the capillary ſyſtem are ſometimes manifeſt to the eye: the differences which can be diſcerned in the arrangement of theſe veſſels are ſpecified partly in the article GLAND; to what we have there ſaid, we may add, that every organic ſyſtem in the body has its peculiar character in this reſpect.

The circulation in the capillaries exhibits, according to the arrangement of Bichat, two kinds of phenomena: *viz.* the motion of the fluids, and the changes which they undergo.

"The blood," ſays Bichat, "when it has arrived in the capillary ſyſtem, is manifeſtly out of the ſphere of the heart's influence, and its motion is continued only by the tonic powers or inſenſible contractility of the part. The veſſels which leave this ſyſtem exhibit motions which do not correſpond to thoſe of the arteries, and which cannot therefore be derived from the heart's action. This aſſertion has been already proved with reſpect to the veins; it is equally true of the excretories. The augmentation and diminution of the ſecretions do not coincide with thoſe of the pulſations of the heart; in violent febrile attacks the whole arterial ſyſtem ſeems violently agitated, yet the functions of the glans are obſtructed, and no fluids are formed. The ſweat is moſt copious after the violent ſymptoms of fever have ſubſided. When an unuſual abundance of ſerous fluids is poured out in various dropſies, the heart's action is weak. That the circulation of the veſſels ſubſervient to nutrition is not derived from the contraction of the heart is equally obvious. The latter force, uniform in the whole body, ſends the blood equally to all parts. Nutrition, on the contrary, is extremely irregular: at one age one organ receives a greater ſupply of nutritive matter, and therefore grows faſter: at another time this diſproportion is obſerved in a different part. Moreover, how can we accommodate to the ſingle and uniform impulſion of the heart in all parts, the different kinds of inflammation, of eruptions, &c. in various

organs? Would inflammation exhibit ſuch varying external characters if the heart alone preſided over its developement? In this caſe all the diſtinctions of catarrhs, eryſipelas, phlegmon, &c. ſhould diſappear, and the only modifications ſhould be derived from the greater or leſs nearneſs of the heart. When, therefore, the blood has arrived at the capillary ſyſtem, it is moved merely by the tonic influence of the ſolids; and as various cauſes modify their properties, it muſt be ſubject to correſponding irregular motions. Hence ariſe the oſcillations noticed by Haller, Spallanzani and others, in their microſcopical obſervations of the circulation; but as theſe occur only in ſome parts at once, they do not affect the general regularity of the return of the venous blood. And this obſervation may be applied to all the diſordered actions of theſe veſſels. When they are more actively exerted in one ſyſtem, they are more quieſcent in the others, &c. Thus, as one part of the capillaries has its action increaſed at the expence of others, the quantity of blood tranſmitted from the arteries to the veins is always nearly the ſame. When we ſee the glands, and the ſerous, cutaneous and mucous exhalants all pouring out an increaſed quantity of fluid, we may be ſurpriſed that the circulation ſhould ſtill go on with preciſion; we ſhall not be leſs ſurpriſed to ſee all theſe evacuations ſuppreſſed. In all theſe caſes, the capillary ſyſtem, of which the vital forces are variouſly modified in the different organs, keeps up the general equilibrium, which would be inevitably loſt if the heart were the agent for expelling the exhaled and ſecreted fluids, and tranſmitting the black blood into the veins. Probably ſudden changes in the ſtate of the atmoſphere may produce general alterations in the capillaries, at leaſt of the ſurface. The ſwelling, which follows the application of a cupping-glaſs, ſhews that the capillary ſyſtem is influenced by atmoſpheric preſſure; and a leſs conſpicuous general effect may be produced by the variations in the general preſſure on the ſurface. Bleeding influences the quantity of blood contained in the capillary veſſels, but it muſt be that kind which is effected by the employment of leeches, cupping, &c. When an artery or vein is opened, we only diminiſh the quantity of blood in the large trunks; there is ſtill the ſame quantity contained in the capillaries of an inflamed part. On the contrary, the maſs of blood may be increaſed by transfuſion, without any local inflammation ariſing, becauſe a previous irritation is neceſſary to attract the blood towards the part.

The fluids, different from the blood, which are contained in the capillary ſyſtem, are alſo removed from the influence of the heart's action, moved by the tonic powers of the part, and conſequently ſubject to irregularities. The nature of moſt of theſe is unknown, becauſe they cannot be ſubmitted to obſervation.

A remarkable phenomenon is exhibited in the general capillary ſyſtem, in the change of the blood from the red to the black ſtate. For the account of the manner in which this change is ſuppoſed to be effected, ſee RESPIRATION. To the ſame article we refer alſo the ſubject of animal heat, the developement of which belongs to the capillaries, although its explanation has been generally ſought in the chemical changes connected with reſpiration.

Of the pulmonary capillary Syſtem.—This includes all the minute ramifications which are the termination of the black, and commencement of the red blood, which conſequently form the end of the pulmonary artery, and the origin of the pulmonary veins. The capillaries, which intervene between the bronchial arteries and veins belong manifeſtly to the general ſyſtem. On the firſt view of the ſubject it will ſeem difficult to comprehend how the general and pulmonary capillary ſyſtems can exactly correſpond to each other; how the pulmonary can tranſmit, not only what paſſes through the general, but alſo all the lymph abſorbed from the ſerous and cellular ſyſtems, the chyle, &c. In fact, a great part of the general capillaries is filled with fluids different from blood, and a greater quantity ſeems to remain habitually in theſe than in the pulmonary veſſels. The whole contents do not paſs into the veins at each pulſation, but only ſuch a proportion as can circulate through the lungs. Moreover ſeveral cauſes are conſtantly drawing aſide the blood, in the general capillaries, from the direction which leads it into the veins; ſuch are the exhalations, ſecretions, and nutrition. In the lungs, on the contrary, it has one courſe only, from the pulmonary artery to the veins, and cannot be diſturbed by a tendency in any other direction, ſince it is employed in no functions in its paſſage from the black to the red ſtate.

The greater and leſs diſtance from the heart aſſiſt alſo in explaining this ſubject. The longer the courſe, through which the blood muſt paſs, the greater length of time will be occupied in its arriving at, and paſſing through, the capillaries; therefore, that which is expelled from the right ventricle will come ſooner to the left auricle than that from the left to the right auricle. Hence, although the velocity ſhould not be greater in the ſmaller circulation, the ſpace which it paſſes through is leſs, and the time is alſo leſs; therefore, the exceſs of the fluid contained in the diviſions of the aorta, in the general capillaries and veins, over that contained in the artery, veins, and capillaries of the lungs, is compenſated by the greater time employed in the paſſage of the former. Hence we may underſtand why, in theſe animals, where the lungs, as far as regards the circulation, are in oppoſition to the whole of the body, nature has placed thoſe organs near the heart.

The circulation in the pulmonary capillaries goes on in the ſame way as in thoſe of the general ſyſtem. Here the blood undergoes the remarkable change by which it is converted from the black to the red ſtate. On this ſubject, as well as for ſome other remarks concerning the lungs, we refer to LUNG and RESPIRATION.

Of the exhalant Syſtem.—Exhalation and ſecretion are two analogous functions, inaſmuch as both ſeparate from the blood fluids different from it; but there are differences between them. In the article GLAND the ſubject of ſecretion is conſidered in a general point of view, and many of the remarks are applicable to exhalation as well as ſecretion. We ſhall particularly ſhew the diſtinctions of the two proceſſes on this occaſion.

In exhalation there is no intermediate organ between the arteries and the exhalants, which are ſeparated merely by a capillary net-work; while, on the contrary, an organ always intervenes between the arteries and the excretory canals: in this are found the capillaries where the former end and the latter begin. Thus it appears that the glands are much more complicated in their ſtructure than the exhalant organs; conſequently, the fluids furniſhed by the former, ſuch as bile, urine, ſaliva, &c. differ eſſentially from the blood, and are moreover very compound in their nature, while the products of exhalation, as the ſeroſity of circumſcribed cavities, &c. reſemble conſiderably ſome parts of the blood, and are compoſed of few elements. The exhaled fluids are poured out from an infinite number of ſmall iſolated tubes, while the ſecretions are collected into one or more principal ducts, which diſcharge them on the ſurface for which they are deſigned. The former return into the circulation in great meaſure, while the latter ſeem eſſentially deſtined to be expelled from the body. Exhalations are performed on an abundance of ſurfaces, as the ſerous, mucous, ſynovial, cutaneous,

taneous, cellular, and indeed in all organs for the purpoſe of nutrition; the ſecretions are poured out only on mucous and cutaneous ſurfaces. Hence, both in ſecretion and exhalation, the capillary ſyſtem is interpoſed between the veſſel that brings, and that which carries away; but in the latter caſe there are capillaries only, while in the former there is an additional organ. In ſhort, glands are neceſſary to ſecretion, and exhalation is performed without them.

Phyſiologiſts have entertained very different notions on the ſubject of exhalation. Boerhaave imagined ſucceſſively decreaſing veſſels capable of admitting colourleſs fluids, but excluding the red globules. Theſe have been commonly rejected by more recent anatomiſts, who have referred exhalation to the tranſudation of fluids through inorganic pores, building their opinions chiefly on the tranſudations which are commonly obſerved in the dead ſubject; but the latter is not a phenomenon of life, while exhalation is manifeſtly influenced by the vital powers.

It muſt be difficult to form any clear notion of veſſels, which, from their extreme tenuity, conſtantly elude our obſervation in their natural ſtate; and our opinions therefore cannot be founded on any direct examination. Injections and inflammation prove the exiſtence of a capillary ſyſtem in thoſe parts from which fluids are exhaled, as the ſerous and cutaneous ſurfaces, &c. If the injected fluid be not puſhed far it is confined to the capillaries; but when it paſſes beyond this point it is depoſited, in minute drops, on the exhaling ſurface, in a ſimilar manner to what happens from the living powers of the part during life. That this is not tranſudation, is proved by the circumſtance of its not occurring in the neighbouring tiſſues. Nothing receives the injected fluid except the arteries, capillaries, and exhalants. In active hæmorrhages from theſe ſurfaces, the capillaries, which give origin to the exhalants pouring out the blood, are evidently more full of blood than is uſual. We may therefore aſſume, as proved, the following points, *viz.* that exhaling veſſels exiſt, that they ariſe in the capillaries and terminate by open orifices on their reſpective ſurfaces. If we go further, and attempt to explain their length, form, courſe, and the nature of their orifices, our deſcriptions will become purely imaginary.

Bichat divides the exhalants into three claſſes. The firſt includes thoſe which ſeparate fluids to be thrown out of the economy, ſuch as thoſe of the ſkin, forming the ſweat; thoſe of the various mucous ſurfaces. To the ſecond diviſion belong thoſe, which form fluids remaining for ſome time on certain ſurfaces, or in various cells, afterwards taken up by the abſorbents and conveyed back again into the circulation. Such are the exhalants of ſerous ſurfaces, which pour out fluids in order to lubricate the membranes and facilitate the motions of the organs covered by them; the cellular exhalants, which form the lymph and fat of the cellular interſtices; the medullary exhalants of the bones; and the ſynovial exhalants of the articular membranes, and of the burſæ mucoſæ. Under the third claſs are arranged thoſe veſſels which convey in all organs the nutritive matter; this is depoſited to repair the loſſes or produce the growth of the part, and is again removed by the abſorbents, to be replaced by new depoſitions. This claſſification is exhibited in the following table.

- Exhalants.
  - 1. Exterior, opening on
    - 1ſt, The ſkin.
    - 2dly, Mucous ſurfaces.
  - 2. Interior, opening on
    - 1. Serous ſurfaces.
    - 2. The cellular ſyſtem, where they depoſit.
      - 1. Serous fluid.
      - 2. Fat.
    - 3. Medullary ſyſtem.
      - 1. Of the ſhort and flat bones, and ends of the long bones.
      - 2. Of the middle of the long bones.
    - 4. Synovial ſyſtem.
      - 1. Of the articulations.
      - 2. Of the tendons.
  - 3. Nutritive. Each organized tiſſue has its peculiar exhalants.

As the exhaling veſſels enter ſo eſſentially into the intimate component ſubſtance of each organ, they muſt differ in each organized tiſſue, but theſe differences do not come under our obſervation.

Properties of the Syſtem, &c.—The veſſels are too fine to admit of our analyſing thoſe properties which depend on their organization. We do not even know whether theſe tubes are enlarged when they admit the red globules, although the fact has been aſſumed by the Boerhaavian ſchool. The expreſſions "groſs" and "ſubtle" fluids are ſtill employed by a multitude of phyſiologiſts, having been introduced by the theory of Boerhaave, and retaining their ground, although that theory has been laid aſide. The exhalants manifeſtly poſſeſs none of the properties of the animal life: they exhibit in a very high degree organic ſenſibility, and the correſponding organic inſenſible contractility, and all their functions are founded in theſe. Yet although the organic ſenſibility be the ſame in its nature in all parts, where exhalants are found, it is ſingularly modified in each ſyſtem: as theſe veſſels are a part of the organic elements, they partake of the properties of each ſyſtem. Hence they ſeparate in every part the peculiar fluids of that part: when much water is contained in the blood, it is diſpoſed of by the cutaneous exhalants; thoſe of ſerous ſurfaces never ſeparate fat, nor the medullary ſerous fluids, although the maſs of blood entering the capillaries is the ſame every where, &c. &c. Thus, too, certain exhalants have a greater tendency than others to admit the blood, and pour it out on their reſpective ſurfaces; as for example, thoſe of the mucous membranes; and ſome of theſe are more diſpoſed to ſuch kind of hæmorrhage than others.

Reſpecting the mode in which exhalation occurs, and the principle on which it depends, we refer the reader to the article GLAND; as there is hitherto no means of diſtinguiſhing between this proceſs and that of ſecretion; in truth we are equally ignorant of the exact nature of the proceſs in both caſes.

When the vital properties of the exhaling veſſels are modified by diſeaſe, they pour out various matters different in their nature and properties from the natural fluids. One of the moſt frequent is blood, and hence ariſes a claſs of hæmorrhages very different from thoſe which ariſe from the rupture of veſſels. The exhalants of the mucous ſurfaces are more particularly diſpoſed to this affection, ſo that it is characteriſtic of that organization. In all ſuch bleedings the membrane is entire, and offers not the ſlighteſt trace of ulceration

ceration or eroſion. Menſtruation is a caſe of the ſame kind, in which the blood is tranſmitted through the exhaling veſſels without any rupture or exhalation. Various other fluids paſs through the exhalants, and hence the differences in the produce of the exhaling organs. How greatly does the cutaneous exhalation differ at different times, and what various fluids are found in the peritoneum under circumſtances of diſeaſe. For a further account of this ſubject, which belongs to pathology rather than to phyſiology, we refer to Bichat's Anatomie Generale.

Exhalants are ſometimes accidentally developed, of which the formation of cyſts furniſhes a remarkable example. The internal ſurface of theſe, which is generally ſmooth, pours out different kinds of fluid, according to the particular ſenſibility of the part. This circumſtance forms another ſtriking diſtinction between the exhaled and ſecreted fluids. The latter are never accidentally depoſited in cyſts; we never meet with preternatural collections of urine, ſaliva, ſemen, &c.; while it is not uncommon to find depoſitions of ſerous fluid, as in encyſted dropſies, of fat, as in ſteatomatous and other tumours, of ſynovia, as in ganglia. It would be neceſſary to the production of ſecreted fluids, that glands ſhould be accidentally developed in the body; but their ſtructure is too complicated, and ſuppoſes the exiſtence of too many conditions for us to expect ſuch a phenomenon. On the contrary, the ſimple organization of exhaling ſurfaces, which preſent merely veſſels continuous with the arteries, and no intermediate organs, can be much more readily produced in parts, to which they are naturally extraneous.

Deſcription of the Heart.—This organ, in which the impelling power of the two vaſcular ſyſtems reſides, is placed in the cavity of the cheſt, between the two lungs. Its figure is conical; it is attached at the baſis to the large blood-veſſels, which confine it to a certain ſituation, and is perfectly looſe and unconnected in the reſt of its ſurface. It is contained in a cavity lined by a ſerous membrane called the *pericardium*; which is alſo reflected over its ſurface.

The pericardium lies in the cheſt behind the 5th, 4th, 3d, and 2d, ribs of the left ſide, and between the two pleuræ, which cover it laterally, and adhere to it by means of a looſe cellular ſubſtance. On the front, a very ſmall portion, or even none of its ſurface, is connected by a little cellular membrane to the middle bone of the ſternum. The baſis, which is round, broader towards the right, and narrower on the left, correſponds to the flat ſurface of the heart, and adheres to the middle tendon of the diaphragm, ſlightly in young ſubjects, but ſo firmly in adults that they can hardly be ſeparated. Moreover it is connected to the muſcular part of that muſcle about the cartilage of the 5th or 6th rib.

The bag which it forms is larger than the heart, ſo that this organ can move freely in it. On account of the greater ſize of the thymus in the fœtus, a ſmaller portion of the pericardium is covered by the pleura than in the adult. It ſurrounds the aorta, pulmonary artery, and veins, as we ſhall deſcribe, is reflected over the ſurface of the whole heart, ſo as to form a membranous bag every where cloſed. This bag is lodged in the lower and anterior part of the mediaſtinum. Its ſize is proportionate to that of the heart, and the large blood-veſſels which it contains; and if it appears larger in the dead body than is neceſſary for holding the heart, this is accounted for by the empty ſtate of the cavities of that organ. Its figure is that of a cone, of which the apex is very round, and of which the baſis, correſponding to that of the heart, has a particular elongation ſurrounding the large veſſels. The front region of this bag is covered by the pleura, except at its middle, where the two laminæ of the mediaſtinum are approaching towards each other. It correſponds to the back of the ſternum, and to the cartilages of the laſt true ribs of the left ſide, from which it is ſeparated laterally by the front of the lungs. The poſterior region, which is the ſmalleſt in extent, correſponds immediately to the front of the œſophagus. The lateral regions are covered by the pleuræ, and by the nerves of the diaphragm; and correſpond to the internal ſurface of the lungs. The inferior region correſponds, as we have ſtated already, to the upper ſurface of the diaphragm. In the adult the adheſion between the muſcle and the membrane is ſo ſtrong that the parts cannot be ſeparated without injury; yet Boyer particularly inſiſts that there is no continuation of aponeurotic fibres from the diaphragm to the pericardium, and that the connection is merely of a cellular nature. Traité complet d'Anatomie, tom. iv. p. 274.

Towards the upper and anterior part of the heart, the pericardium is gradually contracted, and forms an obtuſe proceſs, which adheres to the membranes of the large blood-veſſels at the upper part of the ſternum. It is connected to the inferior branch of the right ſuperior pulmonary vein, then to the ſuperior cava, and to the aorta; it then deſcends to the ductus arterioſus, to the left branch of the pulmonary artery, and each branch of the left pulmonary vein. Behind it is attached to both of the right pulmonary veins, to the left auricle, to both the left pulmonary veins, to the inferior cava, to the ſeptum of the auricles, to the right branch of the pulmonary artery, and to the aorta under the origin of its great branches; it embraces the latter veſſel and the contiguous pulmonary artery in the form of a cylindrical ſheath. But three-fourths only of the aorta are ſurrounded, becauſe the remainder, looking towards the pulmonary artery, adheres to that veſſel by means of cellular ſubſtance. It ſurrounds the ſuperior cava in the form of a ring, ſo that the anterior and poſterior portions of the pericardial cavity communicate together between this vein and the aorta. A ſimilar ring ſurrounds the inferior cava. Hence there are from ſix to eight perforations in the membrane; 1, for the ſuperior cava; 2, for the inferior cava; 3, for the left pulmonary artery; 4, for the right pulmonary artery; 5, 6, 7, 8, one or two for the pulmonary veins on each ſide. Yet we ſhould form an erroneous notion of the ſubject, if we ſuppoſed the membrane to be actually penetrated by theſe openings; it is merely folded backwards, or reflected to cover the large veſſels, the auricles and ventricles of the heart. The folds formed at its reflections cover theſe organs by a kind of ſheaths, and there is no opening in the membrane at any part. According to this repreſentation, if the thin production of the membrane could be removed from the large veſſels and the heart, we ſhould have a complete membranous bag, and the parts juſt named would be clearly ſeen to be on its outſide. The membrane, being reflected over theſe veſſels, and deſcending to the heart, gives them an exterior covering near that organ. When it is inflated, the angles of reflection become more evident, and form two anterior and two poſterior cornua. Deſcending from theſe parts, the pericardium becomes much thinner and more delicate, and is firmly fixed by cellular ſubſtance to the whole external ſurface of the heart, ſo as to give it a ſmooth covering. Fat is collected between this membrane and the heart, about the courſe of the coronary veſſels, more plentifully round the large trunks, and more ſparingly about the ſmaller branches, except in very lean ſubjects.

The pericardium is a white, denſe, and very firm membrane;

brane; rough on the outside from its connection by cellular substance to the surrounding parts; and perfectly polished internally, where it is moistened by a serous secretion. Its strength is so considerable, that although it is very much thinner than the aorta, it will bear a heavier weight after death, without being torn.

Bichat describes the pericardium as being composed of two membranes, a fibrous and a serous one. The former arises circularly from the middle of the aponeurotic centre of the diaphragm, with which it is perfectly identified, ascends round the heart, which it embraces as far as the basis, is continued for some length over the origin of the large vessels, which it conceals, but is soon divided into several distinct sheaths, in order to accompany these vessels to a certain distance. It is confounded with the external coverings of the vessels, and thus ends indistinctly. Its organization bears the most perfect analogy to that of the dura mater, but is rather thinner. It is formed of whitish and irregularly disposed fibres, crossing in various directions, sometimes isolated, and sometimes collected into large fasciculi. These are continued below with the aponeurotic fibres of the diaphragm; and they separate to be prolonged over the vessels above. The serous membrane lines the former, and is prolonged over the heart. It is so intimately connected to the fibrous, that the two may be said to be consolidated, and cannot even be separated, except at the very small spaces where the serous is reflected. The latter adheres by a loose cellular substance to the vessels, but more closely to the heart. The internal surface of this, every where in contact with itself, secretes the serous fluid of the pericardium. On the whole the pericardium belongs to Bichat's class of fibro-serous membranes. He compares the two portions of which it consists, in their relation to the heart, to the dura mater and arachnoid coat in the head. Anatomie descriptive, tome iv.

The arteries of the pericardium are small twigs derived from the internal mammary, phrenic, coronary, &c.; and the veins join the corresponding trunks. The absorbents enter the glands, which lie near the aorta and superior cava. It receives no nerves.

The pericardium possesses the extensibility and contractility, derived from organization. Hence it is accommodated to the varying size of the heart; and hence it yields even if the heart should be distended much more than usual. Its extension in hydrops pericardii proves also its extensibility. Besides the organic sensibility required for the purposes of its nutrition, it possesses a still higher degree which regulates the deposition of fluid from its exhalant arteries. These deposit a moisture, which lubricates the opposed surfaces of the heart, and its containing bag, and facilitates their motions, which is constantly removed by the absorbents during life, but is collected after death, when absorption has ceased into a few drops of a clear yellowish fluid. At a longer time after death this *liquor pericardii* is considerably increased in quantity, by the transudation of the serum separated from the blood contained in the cavities of the heart. In many subjects it exists in great abundance, having been deposited so copiously in consequence of disease during life; and in this case its properties are often altered.

In Nicholson's Journal, vol. 14, a chemical analysis of this fluid is given by Dr. Bostock. He obtained it from the pericardium of a boy who died suddenly. It resembled the serum of the blood in colour and appearance, and left a residue of $\frac{1}{15}$, when evaporated to dryness. The heat of boiling water made it opaque and thready. Oxymuriate of mercury produced copious precipitation; but when the fluid had been boiled, evaporated to dryness, and re-dissolved, the solution was not affected by the oxymuriate of mercury. These experiments shew that it contained albumen. When it was saturated with oxymuriate of mercury, infusion of galls produced no effect, indicating the absence of gelatine. Neutral acetate of lead produced a copious precipitate, even after the fluid had been boiled to dryness, and re-dissolved in water. Nitrate of silver indicated the presence of muriatic acid. According to these experiments 100 parts contain,

Of Water -	92.0
— Albumen -	5.5
— Mucus -	2.0
— Muriate of soda	0.5.

Physiologists generally represent the use of the pericardium, to be that of confining the heart in its situation, secluding it from the surrounding parts, and facilitating its motions by its lubricating exhalation. Dr. Baillie met with an instance in which this covering did not exist; the pleuræ covered the heart, and there was no reason to suppose that any imperfection in the functions of the organ had existed during life. Examples are not uncommon, of complete adhesion between the bag of the pericardium, and the reflected portion of the membrane, without any remarkable influence on the heart's action.

Haller particularly insists on the effects of the pericardium, in bestowing steadiness and precision on the heart's motions. "We can easily see in a living animal, what confusion takes place in the motions of the heart, as soon as it has lost the support of the pericardium. So long as the membrane is entire, the heart is moved equably, each contraction is similar to the preceding ones, and the motions are all executed within the same limits. If the pericardium be divided and removed, every thing is immediately disturbed; the heart in its motions wanders out of its accustomed track, and does not execute two pulsations alike." Elem. Physiol. tom. i. p. 291.

The heart, which is the central organ of the circulating systems, is a hollow muscle, the contractions of which propel the blood into all the arteries of the body. It is situated in the separation of the two laminæ of the mediastinum, and enclosed, together with a certain portion of the trunks of the large blood-vessels connected with it, in the pericardium.

The heart lies behind the sternum, and the cartilages of the last true ribs on the left side; in front of the œsophagus, of the descending aorta, and of the vertebral column, above the diaphragm; below the aorta and pulmonary artery; and between the two lungs which enclose it nearly on every side. It is fixed in its situation by the pericardium, and by the large blood-vessels, over which this membrane is reflected.

Yet its situation undergoes certain changes: resting on the aponeurotic portion of the diaphragm, which is its point of support, the heart follows the motions of this muscle. It descends and passes slightly backwards in inspiration, ascends and comes a little forwards again at the moment of expiration. Obeying the force of gravity, it passes backwards, and falls, if we may use the expression, against the aorta; when we lie horizontally on the back; in the opposite or prone position of the trunk, it comes towards the sternum. When we rest on the right side, the heart inclines towards the right ribs and lung, and liberates the left lung, and *vice versâ*. That these changes do actually take place, may be easily proved by placing the hand on the left side of the sternum, when the beating of the heart can be felt, inspiring deeply and then expiring, or changing the attitude of the trunk so as to place it in the various postures just mentioned. The beating is increased, diminished, or apparently ceases altogether, according to these alterations. Yet we must observe,

obſerve, that the changes produced in the ſituation of the heart by its weight only, are very limited, and that when its pulſations are ſenſible in a very conſiderable extent, or in a different ſituation from what we have deſcribed, the cauſe muſt be ſome diſeaſed affection. A diſtended ſtate of the ſtomach may urge the point of the heart upwards; and the whole organ may aſcend, when the gravid uterus or any other cauſe of diſtenſion affecting the whole abdomen, acts on the diaphragm in that direction. When the fluid of aſcites is ſuddenly withdrawn, it deſcends again, makes different angles with the large veſſels, and carries the aorta down with it.

Inſtances have occurred, but rarely, in which the ſituation of the heart has been inverted; ſo that its point extended to the ribs of the right ſide, and its baſis was towards the left; at the ſame time a ſimilar unnatural poſition has been obſerved in all the large veſſels, and the abdominal viſcera. This unuſual formation does not affect the functions of the organs, which are in every reſpect as perfect as in the more common arrangement.

The volume of the heart, in ſubjects of the ſame age, preſents ſuch numerous varieties, that it cannot be determined with any exactneſs. Soemmerring ſays, that it weighs, together with the pericardium, from 10 to 20 ounces. It is generally larger in proportion to the body, as the ſubject is younger.

The figure of the heart is ſomewhat conical, or it reſembles rather the ſection of a cone, divided by a perpendicular plane carried through it from the baſis to the apex. The point is rounded, and two muſcular and membranous bags of very irregular figures, and in contact with each other, are placed at its baſis. This cone lies obliquely on the diaphragm, with its baſe turned backwards, upwards, and towards the right; and its apex pointing downwards, forwards, and to the left. We diſtinguiſh in this organ a ſuperior and inferior ſurface, a right and left margin, a baſis and an apex.

The ſuperior ſurface (facies major or gibba) is gently convex. That portion of it which belongs to the right ventricle is much broader than that belonging to the left, and the two are ſeparated by a ſuperficial longitudinal groove, continued from the baſis to the apex, and lodging a branch of the left coronary artery. This groove correſponds to the ſuperior margin of the ſeptum ventriculorum. The inferior ſurface (facies minor or plana) is flat and horizontal, and reſts on that part of the pericardium which is attached to the diaphragm. Here the left ventricle occupies a larger ſpace than the right, and is not ſo flat; the two are ſeparated by a groove continued from the baſis to the apex, where it is continuous with that of the ſuperior ſurface. This groove contains the right coronary artery, and a large vein.

The right edge, rather longer than the left, is very ſharp, and inclined forwards and downwards; the left margin is very thick, and turned a little backwards.

The baſis of the heart, turned backwards, upwards, and to the right, adheres to the pericardium by means of the arteries which ariſe from, and of the veins which terminate in this viſcus. The apex, turned forwards, downwards, and to the left, is obtuſe, particularly in the fœtus, of which the two ventricles are nearly equal, while in the adult the left is longer than the right. This apex is almoſt always bifid from the meeting of the grooves of the upper and lower ſurfaces. Of the two parts, into which the point is divided, the anterior, belonging to the right ventricle, is thinner and ſhorter than the poſterior, which is formed by the left. In order to ſee theſe diſtinctly it is neceſſary to remove the fat.

The heart contains four cavities, which are named the ventricles and the auricles. The former conſtitute the largeſt portion of the organ, and ſeem properly to make up the heart; while the auricles are mere appendages placed at the baſis. There is an auricle and a ventricle on each ſide of the heart; and they are diſtinguiſhed by the epithets right and left. But as the heart is placed obliquely, the right ventricle and auricle are turned towards the front of the cheſt, while the left cavities are directed backwards: hence the epithets anterior and poſterior expreſs the ſituation of theſe organs more correctly than right and left. In the early ages of anatomy, when there were no opportunities of examining human bodies, the carcaſes of brutes were employed for the purpoſes of anatomical inveſtigation; in them the poſition of the heart is ſtraight inſtead of oblique, ſo that the two ſides are right and left in their poſition. Theſe names have been transferred to human anatomy, and are now ſo firmly eſtabliſhed in general uſe, that the more correct ones of anterior and poſterior will probably not ſuperſede them.

The auricles communicate with the ventricles by openings, of which the ſize, form, and ſtructure will be deſcribed hereafter. They receive the blood returned from the various parts of the body by the veins: the ventricles expel it again through the arteries. The right auricle (ſinus dexter or anterior, auris or auricula dextra, atrium cordis dextrum, ſinus venarum cavarum) correſponds to the two venæ cavæ and the coronary vein of the heart: the left (ſinus ſiniſter or poſterior, auris or auricula ſiniſtra, atrium ſiniſtrum, ſinus venarum pulmonalium) to the four pulmonary veins. The right ventricle (ventriculus dexter, or anterior or pulmonalis) gives origin to the pulmonary artery; and the left (ventriculus ſiniſter, poſterior, or aorticus) to the aorta. Both the auricles and the ventricles are ſo cloſely connected together, as to form, on external appearance, a ſingle organ: but they are divided on the inſide by a complete partition. The right auricle and ventricle form the right half, or ſide of the heart (cor dextrum); and the other cavities the left ſide (cor ſiniſtrum).

Each auricle and ventricle poſſeſſes two kinds of openings; by thoſe of one deſcription the auricles receive the blood from the veins, and theſe are more than one in each cavity; by the others they tranſmit this blood into the ventricles. In like manner, each ventricle has an opening, through which blood arrives in its cavity, and another, by which it propels this blood into its correſponding artery: the apertures in the auricles then are venous and ventricular; thoſe in the ventricles, auricular and arterial.

The ſtructure of the auricles and ventricles is very different; and this is eaſily explained by a comparative view of their functions. The former cavities propel their blood into the latter through the openings of communication;—conſequently through a very ſhort courſe, which can be accompliſhed by the ſlighteſt impelling power. Hence, theſe cavities are furniſhed with a very ſmall proportion of muſcular fibres, and look almoſt like membranous bags. By the ventricles the blood is to be urged through the arterial ſyſtem which includes, from its origin to its termination, a paſſage of conſiderable length. They are rendered capable of this more powerful exertion by conſiderable muſcular ſtrength, and poſſeſs ſo much larger a quantity of muſcular fibres as to be entirely unlike the auricles. The two ventricles themſelves are very diſſimilar in their thickneſs and ſtrength; the right, which ſends the blood only through the lungs, being much weaker than the left, which has to propel it to the moſt diſtant parts of the body.

The right auricle is placed at the baſis of the correſpond-

ing

ing ventricle, and in close apposition to the left auricle from which it is separated by a thin septum. It is broader and larger than the left; but this inequality, which is sufficiently obvious in the adult, is scarcely perceptible in the fœtus and newly-born child. It is oblong from above downwards, and when distended nearly resembles in figure the fourth part of an oval. We describe in it an external and an internal side, an anterior side, a superior and an inferior extremity. The external side, convex and smooth, is contiguous to the pericardium; the internal is confounded with the left auricle, and the anterior is united to the basis of the right ventricle. The upper extremity receives behind the superior vena cava, which has a course of some length within the pericardium, and descends rather obliquely from right to left, and from behind forwards. On the front this extremity presents a narrow prolongation, or appendix, of a flattened form, terminating in a point, and having very irregular jagged edges; it is placed nearly transversely between the aorta and the right ventricle. A comparison of this loose process to a dog's ear gave use to the appellation of auricula, which was first given to this part only, but has since been extended to the whole cavity. By Latin writers the auricula is still often distinguished from the sinus of the venæ cavæ. The inferior extremity receives the inferior vena cava at its lower and inner part: this vein is much larger than the superior, and does not continue for any length within the pericardium, as it opens into the auricle immediately after penetrating the diaphragm. Its direction is rather oblique from right to left, and from before backwards.

On the interior of the auricle, the external side presents a great number of projections, formed by muscular fasciculi, which are separated from each other by intervals of various length and breadth. They are for the most part parallel, so as to have been compared to the teeth of a comb, and hence named musculi pectinati: they are directed from behind forwards, and communicate together by other smaller fasciculi disposed obliquely in their intervals. The internal side is formed by the septum, which divides the two auricles. In the adult it presents, below its middle, a depression which is named fossa ovalis, although its outline is very nearly circular: here the auricular septum is very thin, being composed of the internal lining only. This depression is deepest above, but its depth gradually diminishes downwards, and it is completely lost below, where the surface is continuous with the inferior vena cava. Towards its upper part, an opening of various sizes, by which the two auricles communicate, is frequently seen; but this is not constant. We have spoken further on this subject in the account of the development of the circulating system of red blood. The surface of the fossa ovalis is sometimes smooth, sometimes irregular, and, as it were, reticulated. The fossa ovalis is circumscribed by a projecting muscular arch, annulus ovalis, isthmus Vieussenii, rubrubiy thick at its upper and middle part, but so much attenuated towards its extremities, or cornua, that it is entirely effaced. These extremities, which are turned downwards, and separated by a small interval, are distinguished by the names anterior and posterior: the former is turned towards the right, is the thickest, and separates the fossa ovalis from the orifice of the coronary veins; the latter is much less prominent.

The anterior side of the auricle presents a large opening, which communicates with the ventricle, and is circular when the heart is distended, elliptical when it is collapsed. Its edge is formed by a firm and whitish zone (tendo cordis venalis), which has been regarded as one of the tendons of the heart, but on accurate examination does not seem to contain any tendinous or muscular fibres. In their descrip-

tions of this part anatomists have varied greatly. Some place a tendon here, and derive the muscular fibres of the ventricle from it; others describe circular muscular fibres composing a sphincter. Senac admits a tendinous structure particularly in old subjects; while Morgagni could hardly discern any thing of that kind even in the bullock. Haller, describing it, says, "firma, pene callosa, tuberculata cellulosa fibria nudam auris membranam cum nuda ventriculi membrana conjungit:" and adds in another place "ego vero lineam reperi, nullam vestigium musculi tendinisve hic reperio."

On the front the superior extremity presents the entrance of the auricular appendix described above: behind is the opening of the superior vena cava. Muscular projecting columnæ of unequal sizes, curved, firmly attached to the sides of the auricle, and variously interwoven form the internal surface of the appendix. The opening of the superior cava is placed perpendicularly over the inferior; and the interval between the two is occupied externally by a thick muscular fasciculus, which has no connection to the fibres of the veins. The sides of the auricle project internally between the two veins in the situation of the fasciculus, but not to any considerable extent: this is the part described by the name of tuberculum Loweri, which, according to the account given by that anatomist, cannot be discovered in the heart.

The inferior extremity of the right auricle presents the orifice of the inferior vena cava, and that of the great coronary vein. On its anterior and left part the former vein is furnished with a small membranous fold, named valvula Eustachii, or nobilis, of which the size varies in different subjects, but is never sufficient to cover the whole of the opening. It is generally larger in the fœtus than in the adult; after birth it not only diminishes in size, relatively to the other parts, but often becomes reticulated at its loose edge, whence it has been described by the name of valvula reticularis. The fold is so inconsiderable in some subjects, that it may be said to be entirely deficient. Its position is nearly vertical, and its figure is that of a crescent. We distinguish in it two surfaces, two edges, and two extremities, or cornua. One of its surfaces is turned backwards, and to the right, and corresponds to the orifice of the vena cava; the other, facing forwards, and to the left, corresponds to the sides of the cavity. One edge is adherent, and the other loose: the first, placed downwards, and rather forwards, is attached to the anterior and left part of the opening of the inferior vena cava; the latter, directed upwards and backwards, is extremely thin, and more or less transparent. One extremity is turned towards the left, and a little backwards and upwards; the other to the right forwards, and a little downwards. The former is attached to the middle and upper part of the anterior column of the fossa ovalis, the latter to the front of the opening of the inferior cava. The Eustachian valve is formed by a fold of the membranes, which line the right auricle; but in many subjects its loose edge forms a kind of net-work. The office of this valve seems to be connected with the fœtal circulation, as the size of the fold is so much more considerable at that time.

The mouth of the great coronary vein is placed between that of the inferior cava, and the aperture of communication with the ventricle, and near to the septum of the auricles. It is furnished with a sufficiently large valve to cover it entirely. The form of this valve is like a crescent, with the convex edge attached, and the concave margin loose; the latter is frequently reticulated. It serves to prevent the reflux of the blood from the auricle into the coronary vein. Besides this there are several other openings from smaller veins, unprovided with valves, into the right auricle.

The left auricle, rather ſmaller than the right, has nearly the figure of a cube, and offers ſix ſides to our conſideration. The anterior is connected to the baſis of the left ventricle: the internal is confounded with the oppoſite auricle: the poſterior, ſuperior, and external are ſmooth and contiguous to the pericardium. From the upper part of the inner ſide an auricular appendix is continued, as in the right auricle; it is ſmaller than on the right ſide, turns forwards, and a little to the right, on the left ventricle, where it lies looſely at the left of the origin of the pulmonary artery. Its figure is nearly triangular, and the ſides are jagged.

The four pulmonary veins, of which two are on each ſide, open into the upper and back part of the auricle. The two of the left ſide are the moſt eaſily ſeen in the pericardium: the right are concealed by the ſuperior cava, and by the neighbouring part of the right auricle.

On the inſide the anterior ſide of the left auricle preſents a circular opening of communication, with the ventricle, ſmaller than that of the oppoſite ſide, and furniſhed like it with a denſe whitiſh circle of a ſuppoſed tendinous nature. The poſterior ſide exhibits the openings of the four pulmonary veins; and the internal contributes to the ſeptum of the auricles. When an opening in the foſſa ovalis leads from the right to the left ventricle, it is ſeen on this ſurface. In the upper edge is ſeen the opening of the appendicular cavity, the ſurface of which exhibits projecting muſcular columns varying conſiderably in number, ſize, and direction, but much leſs numerous and conſiderable than on the oppoſite ſide. The inferior and external ſides are ſmooth, and, as well as the reſt of the auricle, preſent no columns.

The ſides of the auricles have very litle thickneſs: thoſe of the right, thinner than thoſe of the left, are ſemi-tranſparent, and appear merely membranous in many places in the intervals between the muſcular faſciculi, where the ſerous and internal linings are in contact. They are formed of muſcular fibres, placed between two membranes; of which the external is a reflection of the pericardium, and the internal continuous with the lining of the veins, and of the ventricles, which has been already noticed. The muſcular fibres are generally torn when we attempt to ſeparate them from the membrane between which they lie; and are ſo intricately interwoven with each other, that it would be as difficult as uſeleſs to attempt at unravelling and minutely deſcribing their arrangement.

The right ventricle reſembles a triangular pyramid, and offers for our obſervation a ſuperior, an inferior, and a left ſurface; a baſis and an apex. The ſuperior ſurface, conſiderably broader than the inferior, is inclined forwards and to the right; the inferior forms part of the flat ſurface of the heart; both are ſmooth, and contiguous to the pericardium. The left ſurface is confounded with the oppoſite ventricle in a common ſeptum, of which we ſhall ſpeak below. The baſis is joined to the left auricle; the ſuperior and left part gives origin to the pulmonary artery.

On the interior the left ſurface is formed by the ſeptum, which is thicker towards the baſis than the apex of the heart, and perforated by no opening. The ſuperior, inferior, and left ſurfaces, are tolerably ſmooth towards the baſis of the heart, but in the reſt of their extent they exhibit a great number of fleſhy columns (columnæ carneæ), formed by the moſt interior fibres of the ventricle, and varying much in ſize, length, and direction. Three kinds of theſe columns may be diſtinguiſhed. Thoſe of the firſt ſpecies are fixed by one extremity to the ſide of the ventricle, and by the other to the looſe edge of the tricuſpidal valve, by means of ſmall tendinous threads (chordæ tendineæ.) The columns of the ſecond kind are attached by both ends to the ventricle; and thoſe of the third are fixed in their whole length.

The number of the firſt claſs varies very conſiderably in different individuals: often they amount to eight or nine. Their ſize and length are equally uncertain. Some are ſhort, ſo as to reſemble nipples: the longer ones are generally cylindrical, and rounded at the end; and ſome are joined together in various ways: all theſe are directed from the apex towards the baſis of the heart, and they are attached to the inner ſurface of the ventricle more or leſs near to its apex: their points, bifurcated or divided into three portions, give origin to ſeveral tendinous threads, which diverge like the branches of a fan, are, for the moſt part, attached to the tricuſpidal valve, but terminate partly in the ſides of the ventricle. Some of theſe communicate together; and they are ſometimes ſeen to paſs from one column to another. The tendinous threads either go ſtraight to the valve, or they are divided in their progreſs into ſmaller filaments: the ſhorter ones terminate on the looſe edge of the valve, while the longer are continued for a greater or leſs extent upon that ſurface of the valve, which is turned towards the ſide of the ventricle.

The ſecond claſs of columns occupies particularly the anterior or lower third of the ventricle, and is tolerably numerous: they decuſſate each other, and are variouſly connected, ſo as to form a kind of net-work. Thoſe of the third kind are the moſt numerous: they have every variety of ſize and direction, and connection to each other, ſo as to render nearly the whole ventricle very irregular on its ſurface. More or leſs deep depreſſions of various figures are left between them. From this diſpoſition of the muſcular columns, it appears that the ventricle is not ſo much a cavity as an aſſemblage of cavities, or of compartments formed by the interweaving of the muſcular faſciculi, of which the number is very great.

The baſis of the right ventricle has two openings; of which the largeſt, placed downwards and to the right, forms its communication with the auricle, and is called the auricular or auriculo-ventricular orifice (oſtium venoſum): the other, ſmaller and higher, communicating with the pulmonary artery, is named the arterial orifice (oſtium arterioſum.) Theſe are ſeparated by an interval of about an inch.

The auricular opening is furniſhed with a valve, called the tricuſpidal or triglochine, formed by a circular fold of membrane produced from the ſides of the opening towards the point of the ventricle (anulus valvuloſus), and divided at its inferior or looſe edge into ſeveral portions, three of which are generally more conſiderable than the others, and have been repreſented as three diſtinct valves. It preſents two edges, of which one is adherent, and the other looſe and moveable; and two ſurfaces. Of the latter, one is turned towards the ſides of the ventricle, and the other towards the auricular orifice. The adherent edge is attached to the ſides of the opening in its whole circumference; and here the valve is compoſed of a ſingle circular membranous production. The looſe margin is attached to the fleſhy columns of the firſt kind by means of the tendinous threads already deſcribed, and is divided into ſeveral pointed portions, varying conſiderably in number and appearance; three of which are however almoſt conſtantly more conſpicuous than the others, ſo as to have given a name to the valve: of theſe diviſions one, conſiderably broader and longer than the other, is placed upwards and forwards, towards the orifice of the pulmonary artery, which it covers in great meaſure, when it is applied againſt the ſide of the ventricle. This is named by Lieutaud the valvular ſeptum, and is repreſented by him to ſeparate the ventricle into two cavities, of which one, correſponding

reſponding to the auricle, is named the auricular; the other, correſponding to the pulmonary artery, is named the arterial; one of the other two portions is turned downwards and forwards, towards the inferior ſurface and ſharp edge of the ventricle: the other is placed backwards and to the left, towards the ſeptum.

This valve is made up of two membranons layers adhering moſt cloſely to each other: one is a continuation of the lining of the right auricle, the other of the ventricle. They are ſtrengthened by the expanſion of the tendinous threads on their ſurface.

The uſe of this valve is to prevent the blood from flowing back again into the auricle when the ventricle contracts: It lies againſt the ſide of the cavity, where the blood paſſes through the auricular opening; but when the ventricle contracts, the three portions are raiſed from this ſituation, and meet together ſo as to cloſe the opening: theſe facts may be obſerved by injecting any fluid in the dead ſubject contrary to the courſe of the blood.

The arterial opening of the right ventricle (oſtium arterioſum) is much ſmaller than the preceding, and is marked by a callous ring (tendo cordis arterioſus), which terminates the fleſhy part of the heart, and marks out the origin of the artery. We have already deſcribed, in the account of the arterial ſyſtem, how the artery and ventricle are united. The entrance of the pulmonary artery is furniſhed with three valves, called the ſigmoid or ſemilunar, which exactly reſemble, in their ſtructure and diſpoſition, the valves of the veins deſcribed in a former part of this article. As they are deſigned to prevent the reflux of the blood towards the heart, their attached edge is turned towards the ventricle, and their looſe margin towards the trunk of the artery. The looſe edge is rather thicker than the reſt of the valve, and has a ſmall tubercle about its middle (corpora ſeſamoidea, or Arantii.) This part is not always equally evident, and even ſeems to be entirely deficient in ſome caſes. The ſigmoid valves in the adult are ſometimes ſtrengthened by whitiſh ſhining fibres, which appear to ariſe from the cornua of the valve, and extend to various diſtances on the ſurface. The action of theſe valves is completely mechanical, and may be obſerved in the dead body by injecting contrary to the blood's courſe. They lie againſt the ſide of the artery, where the ventricle contracts; and are ſo thin as not to interfere with the tranſmiſſion of the blood through the opening. When any fluid comes in the oppoſite direction, it raiſes their looſe edges, fills the ſacs intercepted between the valves and the artery, and preſſes the margins together, ſo as completely to prevent all paſſage in this unnatural courſe.

The left ventricle is longer than the right, and extends rather further at the apex of the heart. Its figure is that of a cone a little flattened on the ſide by which it is united to the right ventricle. We conſider in it a right and left ſurface, an apex, and a baſis. The right ſurface is confounded with the right ventricle; the left, contiguous to the pericardium, makes part of the upper and lower ſurfaces of the heart. The apex is obtuſe, and forms the largeſt part of the point of the heart: the baſis is joined to the correſponding auricle. The upper and right part gives origin to the aorta.

The cavity of this ventricle preſents the ſame three kinds of muſcular columns as have been mentioned in the deſcription of the right. Thoſe of the firſt kind are larger but leſs numerous than in the right ventricle: their apices are more conſtantly bifurcated, or even divided into three portions. The tendinous threads are very numerous, and are of a ſize proportioned to that of the columns. They diverge in a fan-like manner, and are attached to the looſe edge of the mitral valve; but ſome are connected to the ſides of the ventricle. Of thoſe, which are attached to the valves, ſome paſs without any alteration from their origin to their inſertion: others divide into ſeveral branches, and ſome communicate together ſo as to form a kind of net-work. The length of theſe threads is not uniform: ſome exceed an inch, while others are more than two or three lines in length. The columns of the ſecond and third kinds are much leſs numerous and large than in the right ventricle. They are altogether deficient near the orifice of the aorta, where the ſurface of the ventricle is ſmooth. The baſis of this ventricle poſſeſſes two orifices correſponding to thoſe of the oppoſite ſide: *viz.* a larger auricular, and a ſmaller arterial opening.

The auricular orifice, (oſtium venoſum,) ſmaller than that of the right ventricle, is bounded like it by a kind of whitiſh zone, from which there is a membranous production, deſcending into the cavity of the ventricle, where it is divided into two portions, and conſequently named the mitral valve, which, in all the eſſential parts of its conſtruction, reſembles the tricuſpidal; like that it has two ſurfaces, one turned towards the ſides of the cavity, and the other towards the auricular orifice; it has alſo two edges, of which the adherent one is attached to the whole circumference of the auricular orifice, and the looſe one is connected by the tendinous threads to the fleſhy columns of the ventricle. The latter margin is conſtantly divided into two portions, an inferior and ſmaller, a ſuperior and larger one, correſponding to the mouth of the aorta, which it covers almoſt entirely, when the ventricle is dilated.

The latter is the valvular ſeptum of Lieutaud, who conceives that it divides the cavity of the ventricle into an auricular and an arterial portion. Between theſe two portions the mitral valve is not more than one or two lines broad. The mitral valve is conſiderably thicker than the tricuſpidal, and often beſet at its looſe edge with ſmall, callous, and hard tubercles. Its uſe is juſt the ſame on the left, as that of the tricuſpidal valve is on the right ſide of the heart.

The arterial orifice of the ventricle is ſeparated from the auricular only by the attachment of the large portion of the mitral valve; and from that of the pulmonary artery, merely by the thickneſs of the ventricular ſeptum. It is marked by a callous ring, as on the oppoſite ſide, to which its arrangement is ſimilar in every reſpect. Three ſigmoid or ſemilunar valves are placed at the mouth of the aorta, as in the pulmonary artery: they are larger and thicker than thoſe of the latter, and have more conſiderable tubercles on their looſe edges. Their office is juſt the ſame in the aorta, as that of the others in the pulmonary artery. The ſides of the aorta, oppoſite to the ſituation of the valves, ſwell into three ſmall tumours, and there are the ſame number of ſmall cavities on the inſide, called the ſmall ſinuſes of the aorta; as theſe do not exiſt in the fœtus, they may be conſidered to ariſe from the efforts of the blood againſt the veſſel.

The two ventricles are ſeparated by a muſcular partition, which is thickeſt at the baſis, and grows gradually thinner to its termination at the apex of the heart. In this the fibres of the two ventricles are mixed together, ſo that it does not belong entirely to the left. It projects into the cavity of the right ventricle. Its whole ſurface has a reticulated appearance, in conſequence of its poſſeſſing fleſhy columns like thoſe already deſcribed; and there are little depreſſions in the intervals of theſe, which were conſidered by the older anatomiſts to be openings of communication between the two cavities. The latter opinion is now completely exploded, and the partition is allowed to be perfect.

It has been the generally received opinion, that the right

ventricle is more capacious than the left; but this point has been controverted. Anatomiſts have endeavoured to decide the queſtion by meaſuring the quantity of fluid which can be introduced by the way of injection; and in theſe experiments Haller has ſometimes found that the right would hold 24 drams, when the left would contain little more than eight. Winſlow and Senac agree with Haller in aſſigning a greater capacity to the right ventricle, as well as to the correſponding auricle. However, Sabatier refers the apparently greater ſize of the right after death to the congeſtion in the right cavities, which occur at the time of death, and aſſerts, that the left will be the largeſt, if the animal be ſo killed as to produce a congeſtion on that ſide, and liberate the right.

The fleſhy fibres of the ventricles are very cloſely arranged, ſo that the heart contains a greater quantity of fibres, under a given bulk, than any other muſcular organ in the body. Theſe fibres are connected by a very ſhort and denſe cellular ſubſtance; are not collected into diſtinct faſciculi ſurrounded by a looſer medium, as in other muſcles; and are interwoven with each other in ſo inextricable a manner, that the deſcription of their direction and arrangement becomes very difficult. They are all more or leſs oblique, but in ſuch a manner that they approach more nearly to the tranſverſe than to the longitudinal direction; and none extend directly from the baſis to the apex of the heart. Their origin cannot be ſettled: they are not continuous in their courſe from the baſis to the apex of the heart: and their inſertion is equally uncertain. They ariſe from all points of the ſurface of the ventricles, and they ſeem to terminate as generally. Thoſe of the two ſides decuſſate at acute angles in the ſeptum. Towards the interior numerous portions are detached to form the fleſhy columns already deſcribed. The fibres of the ventricles are every where ſo cloſely connected, that the various ſtrata which they form cannot be ſeparated and uncovered without lacerating them conſiderably.

The ſurface of the ventricles is covered by a delicate membrane, which is the reflection of the pericardium in a very thin ſtate, much thinner indeed than upon the auricles. Its external ſurface is ſmooth, conſtantly moiſtened by a ſerous exhalation, and contiguous to the bag of the pericardium. Its internal ſurface is united to the ſubſtance of the ventricles by a very fine cellular membrane, in which fat is collected. This fat, of which the quantity varies in different ſubjects, is more abundant at the baſis and apex of the heart, and in the courſe of the coronary arteries, than elſewhere. It is found in much ſmaller quantity on the auricles than on the ventricles. It hardly exiſts in the heart of the fœtus; and ſometimes is not obſerved at all on the ventricles of ſubjects three or four years old. It becomes depoſited more abundantly as the individual advances in life; and is always ſeen in conſiderable quantity in old perſons. It varies conſiderably in the hearts of younger individuals, which are almoſt free from fat when the ſubject has been emaciated or anaſarcous, and as remarkably loaded in the corpulent.

The cavities of the ventricles are lined by continuations of the membranes, which cover the inner ſurface of the auricles, and which have been generally deſcribed in the account of the organization of the two circulating ſyſtems. It is extremely thin in the heart, where it ſeems merely deſigned to give a ſmooth ſurface for the paſſage of the blood, without contributing at all to the ſtrength of the organs. It is moſt cloſely attached to the ſurface of the muſcular fibres, both in the ventricles and auricles, by a very fine and ſhort cellular ſubſtance, in which no fat is ever obſerved. The extent of the membrane is very conſiderable, as it is folded to form the different valves of the heart, covers all the projecting columns, and deſcends into the excavations between theſe.

The arteries of the heart are two in number, and named the coronary: they are the two firſt branches of the aorta, ariſing about oppoſite to the looſe edges of the ſigmoid valves. The exact ſituation of their origin has been much diſputed; with reference to a peculiar opinion concerning the action of the heart. "In numerous examples," ſays Haller, "I have conſtantly found the origins of theſe arteries higher or further from the heart than the ſinuſes of the anterior and poſterior valves, in which cavities ſome have ſtated that they ariſe. In the dead ſubject it is not eaſy to extend the valves ſufficiently to cover the openings of theſe veſſels. The callous white line, which bounds the upper edge of the valvular ſinuſes, and correſponds to the looſe edges of the valves, is placed under the orifices of the coronary arteries. If the aortic valves covered theſe openings, the coronary arteries would receive their blood at a different time from the other branches of the aorta; the blood paſſing through the aorta would preſs the valves againſt the ſide of the canal, and cloſe the coronary arteries, which muſt therefore be filled by the retrograde blood, and conſequently have their ſtream of blood accelerated, when the heart is dilated. Now this is not the caſe: we can eaſily ſee in living animals, that the veſſels of the heart pulſate with the other arteries; and if one of them be opened, the jet of blood is increaſed when the heart contracts, and falls lower when it is dilated." (Element. Phyſiol. lib. 4, ſect. 3, § 30.) The diſtribution of theſe arteries is deſcribed in the article ARTERY. The veins of the heart, of which nearly the whole unite into the great coronary vein, which opens into the right auricle, are deſcribed under VEIN. It has been aſſerted, both of the coronary arteries and veins, that many of their minute branches, and particularly thoſe of the latter, open on the ſurface of the various cavities, eſpecially of the auricles. This was firſt ſtated by Vieuſſens, who affirmed that air, water, or quickſilver would be tranſmitted through theſe openings. Thebeſius wrote a particular work on the ſubject, and the openings in queſtion have ſometimes been named after him foramina Thebeſii. Senac, Duverney, and others aſſert that injected fluids will not take this courſe. Haller admits that there is an exudation on the internal ſurface of the cavities, ſimilar to what occurs in other parts of the body; and conſequently, if we repoſe any faith in theſe experiments, and conſider them to afford a legitimate foundation for inferences concerning the ſtate of parts during life, we muſt allow that there is an exhalation into the cavities of the heart, of which, however, we have no direct proof.

The heart and pericardium have numerous abſorbing veſſels, which take up the fluid depoſited by the exhalants of that membrane; we do not know whether they abſorb any thing from the internal ſurfaces of the cavities.

The nerves of the heart are derived from the par vagum and from the great ſympathetic. They are ſmaller than thoſe of any muſcles in the body: the cardiac nerves in fact are diſtributed upon the aorta and the coronary arteries. See NERVE.

Fœtal Heart.—This organ is one of the firſt viſcera ſeen in the embryo, as we find in it the cauſe of life, and of the circulation, and conſequently the immediate ſource of the formation, growth, and nouriſhment of parts. The motion, ſays Haller, which is perceived at the end of the ſecond day in the incubated chick, at that time white and colourleſs, is diſcovered, by the alternate riſing and falling, to be derived from the heart. Before all the other viſcera, the heart exhibits its conical figure, firmneſs of ſtructure and irritability, and ſeems alone to fill the cheſt, when the brain is like whey,

whey, the lung hardly viſible, the ſtomach, liver, inteſtines, and kidnies confuſed together, under the appearance of a white jelly; when there are no appearances of extremities, very few veſſels, and rather ſome kind of paſſages delineated in the umbilical membrane, than true blood veſſels; when in ſhort all other parts are comparatively ſmall and imperfect. Hence the proportion of the heart to the reſt of the body in the fœtus is very conſiderable; and particularlyſo in the incubated chick, the heart of which is a little leſs than the head at the end of the ſecond day, but thicker than the whole body, of which it forms about $\frac{1}{2}$, or a larger ſhare. At a more advanced period of fœtal exiſtence, this organ is ſtill very large, and occupies the greateſt portion of the cheſt. It is broader and not ſo long as in the adult, and conſequently has a more rounded figure. On opening the cheſt it is immediately ſeen, covering and hiding the lungs, which on the contrary ſurround it almoſt entirely in the adult. The pericardium is thin, tender, and tranſparent, and eaſily ſeparable from the diaphragm. The auricles are larger than the ventricles, whereas, after birth, the latter cavities very much exceed the former in ſize. Wriſberg found the auricles ſo large in the embryo of three months as to cover the greateſt part of the heart.

The left ventricle is more advanced in its formation at an early period than the right, as it receives the blood of the inferior cava through the foramen ovale and the left auricle. The younger the fœtus, the ſmaller is the right, and the larger is the left ventricle. As the time of birth approaches, the relation of ſize between theſe parts is altered, and the two are nearly equal. The right ventricle is as long as the left, ſo as to make the point of the heart very obtuſe.

The muſcular thickneſs of the two cavities is nearly equal in the fœtus: the right propels its blood through the canalis arterioſus into the general arterial ſyſtem, and therefore requires greater ſtrength than is neceſſary after the obliteration of that canal, where it tranſmits the blood only through the ramifications of the pulmonary artery. A large opening of an elongated oval figure (foramen ovale or Botalli) is found in the ſeptum of the auricles, and forms a communication between thoſe two cavities. Its poſition is oblique, one end of the oval being directed upwards, forwards, and to the right; the other downwards, backwards, and to the left. The margin of this aperture is rather thicker than the reſt of the ſeptum, and repreſents a ring (the limbus foraminis ovalis or iſthmus of Vieuſſens, ſphincter of Mery, anulus ovalis of Haller) incomplete at the part which looks towards the inferior vena cava, and compoſed of curved muſcular fibres, covered by the internal membrane of the heart, which at the margin of the foramen is continued from one auricle to the other. In ſome inſtances the ring is complete. The younger the fœtus is, the larger is this opening, ſo that there ſeems to be ſcarcely any auricular ſeptum. A valve of a ſemilunar figure (valvula foraminis ovalis), with its looſe edge in the left auricle, occupies this opening. The convex edge of this valve is fixed to the inferior and lateral portions of the foramen; the ſmaller concave and looſe margin is contiguous to the upper part of the ring, and the interval between the two conſtitutes the oval opening. The extremities of the creſcent, formed by the looſe edge of the valve, called by Haller cornicula, are turned upwards, attached to the two ſides of the opening in the left auricle, and ſeparated by an interval of about four lines in the fœtus at full time. The valve is a fold of the internal lining of the auricles, its two ſurfaces being prolongations of the membranes of the cavities towards which they are placed, and being continuous with each other at the looſe concave edge. It is ſo thin as to be nearly tranſparent, and conſequently differs from the reſt of the auricular ſeptum. Sometimes muſcular fibres may be diſcovered within the duplicature of the membrane. The valve preſents very different appearances at different periods of time before birth: in the very early times there are no traces of it. In the third and fourth months we firſt obſerve its rudiments, but it is narrow. As it grows broader, its edge approaches the margin of the foramen ovale, and is as high as that in the ſixth month; in the ſeventh the whole concave edge has paſſed above the margin of the ring, ſo that the foramen is completely covered by it. In the mature embryo the cornicula reach two or three lines above the opening, and the valve itſelf is one or two lines larger than the aperture: hence, when the parts are ſtretched, there ſeems to be no opening, but when the valve is left to itſelf, it yields towards the left auricle, and an elliptical ſpace is left between its edge and that of the opening. Preſſure on its ſurface from the left auricle only applies it againſt the margin of the aperture, ſo as to prevent all communication. At this time then the foramen ovale is a ſpace included between two concave edges, of which one (that of the anulus ovalis) has its cornua turned downwards, the other (that of the valve) has them directed upwards. So long as there is a preſſure from the right auricle, theſe margins may be ſeparated, and fluid may paſs; but when the force is equal on both ſides, the opening is cloſed, and the blood does not get through, although the margins are ſimply contiguous and not adherent. They do, however, in general, adhere ſoon after birth.

The Euſtachian valve is moſt perfect and large in the fœtus, in which it is never reticulated. Hence we conclude that its office is particularly connected with the peculiarities of the fœtal circulation. Its ſtructure and direction lead us to aſcribe to it the office of conducting the blood from the inferior cava to the foramen ovale, and oppoſing its entrance into the right auricle. Hence this valve has been found unuſually large and ſtrong when the foramen ovale is open in the adult. Soemmerring de corporis hum. fab. t. 5. p. 16.

The general diſpoſition of this opening ſhews that the courſe of the blood through it muſt be from the right to the left; the reflux is mechanically prevented. This view of the matter coincides with the inferences which would be drawn from the ſmallneſs of the lungs and the want of reſpiration, and the conſequently ſmall quantity of blood arriving through the pulmonary circulation at the left auricle. The communication by the foramen ovale opens a direct paſſage for the blood of the umbilical vein to the left ſide of the heart. In this general ſtatement all phyſiologiſts agree; but ſome ſuppoſe that the blood of the inferior cava in particular goes through the opening, while others do not make this diſtinction. An account of the former, which is the opinion of Sabatier, will be ſeen in the article CIRCULATION.

Various unuſual formations occur in this eſſential part of the circulating ſyſtem. In ſome rare caſes the heart has been entirely wanting, (ſee Mem. de l'Academie des Sciences, 1740, where an example is mentioned by Winſlow, the ſame work in the year 1720, where there is a caſe by Petit, and the Philoſophical Tranſactions for 1809). The details of the anatomy of the circulating organs in theſe inſtances have not been ſtated with ſufficient minuteneſs to enable us to underſtand how the circulation was carried on without this eſſential organ. All the children came into the world dead.

A more common kind of malformation conſiſts of ſuch arrangements as produce a mixture of the red and black blood, and are conſequently attended with the moſt unfavourable effects on the general economy. Of this kind are

openings

openings in the baſis of the ventricular ſeptum, over which the aorta uſually ariſes in ſuch caſes. In theſe inſtances the communication of the pulmonary artery with the right ventricle is generally by an unnaturally ſmall aperture. Sometimes the aorta has ariſen out of the right ventricle, and the pulmonary artery from the left. In ſome of theſe caſes the canalis arterioſus is more or leſs pervious. Theſe deviations from the natural ſtructure of the parts muſt be attended with a great derangement of the functions of circulation and reſpiration; the red blood, which ought to be perfectly ſeparated from the black, is more or leſs mingled with it, and the two are ſent together to all the organs of the body. Hence there is a lividity and coldneſs of the whole frame, and a languor in all the functions. In many inſtances, too, the quantity of blood ſent to the lungs is much leſs than uſual, and all the inconveniences are therefore neceſſarily aggravated. The individuals in whom theſe malformations occur, are ſubject to fits of every difficult breathing, and great anxiety and general diſtreſs whenever any cauſe tends to accelerate the circulation. The duration of their lives ſeldom extends beyond a few months; but it may be protracted to ſome years where the malformation allows a conſiderable portion of red blood to be circulated in the body. See the Medical Obſervations and Inquiries, vol. vi.; Medical Tranſactions, vol. iii.; Sandifort's Obſervationes Anatomicæ; and Dr. Baillie's Morbid Anatomy.

On the ſubject of the properties of the heart, we muſt refer the reader to the general account of the organic muſcles, under the article Muscle. We have a few remarks only to make here.

The extenſibility of the heart is ſeen in its dilatation to an unuſual ſize, when a larger quantity of blood than is natural is contained in any of its cavities. This we ſee very commonly in the right auricle and ventricle, which are found full of blood at the inſtant of death, becauſe this fluid finds an obſtacle to its tranſmiſſion through the lungs, and is conſequently accumulated on the right ſide of the heart, as it arrives from all parts of the body. Very few hearts do not preſent theſe dilatations in various degrees; and we may increaſe or diminiſh them, according to the kind of death by which we kill an animal. We ſhall ſcarcely ſee two hearts of exactly the ſame dimenſions in the dead body; and theſe varieties depend on the greater or leſs difficulty experienced by the blood in the laſt moment in paſſing through the lungs. Hence, in affections of the heart, we have no natural type to which the diſeaſed bulk can be compared. This phenomenon, which ariſes merely from the extenſion of the undiſeaſed cardiac cavities, muſt not be confounded with the aneuriſmatic enlargements of the heart. The left ſide of the viſcus often exhibits twice or three times its natural volume, and is at the ſame time increaſed in thickneſs; here there is an unnatural growth, and the enlargement is produced by nutrition, not by diſtenſion. When the latter cauſe acts, there is no additional ſubſtance; there is a loſs of thickneſs correſponding to the increaſed ſize. When the diſtended heart is punctured, the eſcape of the contained fluid is followed by a reduction of ſize; but the aneuriſmatic heart does not regain its natural dimenſions on the evacuation of its contents.

The contractility of the heart makes it contract when the diſtending cauſe ceaſes to act. Thus, when an animal dies of hæmorrhage, all the blood is withdrawn from the heart; its cavities contract to the utmoſt, in conſequence of being quite empty, and the organ appears very ſmall. When much blood diſtends the cavities, as in aſphyxia, an oppoſite condition of the organ is obſerved; and there is every intermediate degree between theſe.

That the heart does not poſſeſs animal ſenſibility is obvious from the reſult of experiments, in which animals do not ſhew ſigns of pain, when the organ is injured. It has been alſo proved, that the irritation or diviſion of its nerves does not affect its action. The nerves of the eighth pair, and the trunks of the great ſympathetics, have been many times divided; the animals die after a longer or ſhorter interval from the derangement of other functions; but the action of the heart is continued as long as they live, perhaps for one, two, or three days. The ſame reſult has been obtained from dividing the medulla ſpinalis in the neck. It does not appear in theſe caſes that death begins in the heart; the moſt ſtriking circumſtances are obſervable in the reſpiratory functions, which are performed with great difficulty. Accordingly, we may conclude that the brain does not influence the heart's action; and this correſponds to the integrity of its functions in apoplexy, compreſſion, &c. where all the organs deriving their powers from this part have their offices ſuſpended.

The ſympathies of the heart are ſtrongly marked and very univerſal; every impreſſion of any magnitude in the economy almoſt inſtantly affects the motions of this organ, which are often deranged, even by a ſlight wound or an inconſiderable degree of pain. Theſe derangements are of two kinds: in one caſe the action of the part is momentarily arreſted, and ſyncope enſues, which often appears under the impreſſion of conſiderable and ſudden pain. It happens, however, moſt frequently, that the heart's action is accelerated; hence the frequency of febrile affections in all local diſeaſes; theſe are purely ſympathetic, and ceaſe when their cauſe is no longer preſent. In many inflammations, the cauſe is too local to allow of our admitting with Boerhaave an obſtacle to the blood's courſe, which excites the heart to increaſed exertion in order to ſurmount it. Moreover, if there ſhould be no obſtruction, but merely pain, and febrile irritation ſupervenes, the effect muſt be ſympathetic. That the increaſed action of the heart may depend on the admixture of a foreign ſubſtance with the blood, which renders it more irritating, cannot be denied; but in the greater number of caſes it is more conſonant to the general laws of the economy to refer it to that unknown influence, which unites all the organs, which connects together all their actions, and holds them in a ſtate of reciprocal dependence.

In the article Circulation we have mentioned, as the cauſe of the heart's dilatation, the admiſſion of a freſh portion of blood into its cavities; on which ſuppoſition the organ appears to be paſſive in its enlargement. But the following arguments of Bichat render it doubtful whether this ſuppoſition be altogether juſt. Expoſe the heart and empty it, if a ſtimulus be applied, it will ſtill contract and dilate alternately, as if it were full. Puncture all the large veſſels connected with the organ, ſo as to evacuate it entirely; the alternate contractions and dilatations ſtill continue for ſome time. Remove two hearts of equal volume from two living animals, place the fingers in the ventricles of one, and graſp the other in the oppoſite hand, you will then find that the effort of the latter, in its dilatation, is as forcible as that of the former in its contraction. When the heart is irritated with the point of a knife it uſually contracts; but ſometimes it dilates firſt, and contracts ſubſequently.

Motions of the Heart.—The common definition of this organ, that it is a hollow muſcle, leads us to conclude beforehand, that all its motions are for the purpoſe of contracting or enlarging its cavities—the common function of all muſcles. So long as life continues this contraction goes on with conſiderable celerity and force; when the animal languiſhes it

becomes

becomes weaker, aad ceaſes altogether at the time of death; ſo that it is the offspring and attendant of the vital powers, "vitæ filia viriumque animalium," in the language of Haller. The contraction of the heart (ſyſtole), in which the ſides are approximated ſo as to efface the cavities, is performed for the purpoſe of expelling its contents. When this is completed, the organ paſſes into the ſtate of dilatation or remiſſion (diaſtole), in order to admit a freſh ſupply of blood. This interval between two contractions has been generally regarded as a paſſive ſtate; and Haller identifies it completely with the condition of the organ after death, obſerving that the only difference is, that the cavities are full in the one caſe and empty in the other. "Hoc alterum cordis ſtadium in vivo animale alterna requies, in cadavere mortis et inertiæ ſtatus eſt." The arguments adduced in the preceding paragraph render it doubtful how far this is true, and lead us to conclude that the dilatation, as well as the contraction, is the reſult of ſome active power; at all events, we ſhall not be likely to admit that the ſtate of the living heart between two contractions is the ſame with that of the organ after death. The contraction then muſt be regarded as the moſt active part of the phenomena; the dilatation having for its object only the production of new contractions.

In whatever part we obſerve the muſcular fibres of the heart, we ſee them croſſing irregularly in all directions. This general decuſſation, apparent at firſt ſight in the right auricle, where the muſcular faſciculi are in great meaſure inſulated, and very obvious on the internal ſurface of the ventricles, where they project, is rendered manifeſt by the aid of diſſection in the ſubſtance of the parietes both of the ventricles and of the left auricle. Hence we infer that the cavities are contracted, and equally diminiſhed in ſize in all directions at once. But a common ſeptum ſeparates the auricles, and a common ſeptum ſeparates the ventricles. Theſe correſpond to each other, are continued together, and form the boundary dividing the two ſides of the organ. The blood arrives at the ſame inſtant through the venæ cavæ at the right auricle, and through the pulmonary veins at the left; conſequently, the two ventricles are filled at the ſame inſtant. Hence the two auricles contract together, and the two ventricles contract together in the next period of time. In both cavities the blood is preſſed from all ſides, and with an equal force againſt the common ſeptum; which cannot be carried towards one ſide or the other, but remains motionleſs, and experiences only a diminution of its breadth. Thus, the firſt remarkable fact exhibited to us in the motions of the heart taken altogether, is, that the proper parts of the cavities approximate to their common part, which is the central and fixed point.

When the contractions of the ventricles are obſerved in living animals, the external fibres are corrugated, and theſe wrinkles are attended with tremor and palpitation, particularly when the animal is in a weak ſtate, at which time they often begin in ſeparate portions, which appear to unite into a general contraction. But, where the powers have not been exhauſted, the whole of each ventricle is contracted at once; and the circumference approaches to the ſeptum. At the ſame time the apex is attracted towards the baſis, becomes ſhorter and more obtuſe, and is ſlightly turned forwards; conſequently, the whole heart is ſhortened. This latter fact, which was formerly conteſted, is now univerſally received. The motion begins from the apex, and is propagated towards the baſis, which deſcends a little; this, compared to the aſcent of the apex, is in an inverſe ratio to the firmneſs with which they are fixed in their reſpective ſituations. On opening the heart, it will be ſeen that the ſeptum is rendered ſhorter; and that the columns attached to the valves are ſhortened, and brought nearer to the auricular openings, ſo that the tendinous threads are relaxed.

The heart does not undergo merely a change of figure in its ſyſtole, but is alſo moved in its ſituation;—experiences a general locomotion. The apex, in approaching to the baſis, deſcribes an arc of a circle about the baſis, which is fixed towards the right and front, as the extremity of a radius moves upon its centre, and ſtrikes at the end of this motion the fifth or ſixth rib. That this happens on the ſyſtole of the ventricles is clearly aſcertained; and Harvey had an opportunity of obſerving in the human ſubject that the organ ſtrikes againſt the cheſt when it is contracted. The explanation of this phenomenon is given in the article CIRCULATION.

In the contraction of the right auricle all its dimenſions are reduced. The upper portion is corrugated, and depreſſed towards the heart; and the motion of the whole cavity is from above downwards, as it is ſtrongly connected to the baſis of the heart in one direction, and unattached in the other. This is the reverſe of what happens in the ventricles, where the motion is from below upwards. The auricular appendix is at the ſame time erected and curved: the convexity of the organ is deſtroyed, and the part, which formed the arc of a circle, made nearly ſtraight; hence the right ſide of the cavity is drawn towards the left, and the tranſverſe diameter conſequently diminiſhed. The ſame phenomena occur on the left ſide.

Since all the diameters of the cardiac cavities are reduced in the contraction of the organ, theſe receptacles muſt be leſſened, and their contained fluids expelled. It is very obvious that this takes place in living animals; and the finger introduced into the ventricle, at the time of its contraction, experiences conſiderable preſſure. Whether the heart expels its whole contents is doubtful. In animals dying under the hand of the experimentaliſt, ſome blood certainly remains behind, and conſiderable quantities are found in the heart after death. Haller conſiders, that in a living and healthy animal the whole contents are driven out, and that the appearances in experiments, where the cheſt is opened, and the creature exhauſted by tortures, cannot afford a criterion of the natural proceſs. He ſtates, that if a ſmall quantity remained behind, it would excite perpetual irritation, and excite a conſtant exertion of the organ, which would prevent the accuſtomed relaxation from taking place. For the ſmalleſt portion of froth produces an inceſſant contraction of the heart in a frog; and when the ventricles in a living animal were evacuated, as completely as poſſible, by preſſure, the ſmall quantity left behind prevented the heart from reſting. In cold blooded animals the heart becomes pale in its ſyſtole, which could not happen, unleſs the red blood were completely expelled. The auricles too of warm blooded animals, which are of a violet colour, on account of their thinneſs, when diſtended with blood, are pale and colourleſs when contracted. Laſtly, ſays Haller, in numerous experiments on the incubated chick, where the blood is intenſely red, I conſtantly found that it was ſo completely expelled from the white and pellucid heart, that the organ remained colourleſs.

In deſcribing the ſyſtole of the heart, we may be conſidered as repreſenting the diaſtole alſo; for in the latter an oppoſite condition prevails in every reſpect. The wrinkles of the fibres are loſt, and the whole viſcus becomes ſmooth, level, and ſoft: it is extended into a greater length, the baſis retreating from the apex, and the apex from the baſis, and at the ſame time turning backwards, and to the left. The

fleſhy

fleſhy ſides of the ventricles ſeparate from the ſeptum. The auricles paſs into their former ſtate, their convex ſurfaces aſcending, and being again ſtretched out. In this relaxed ſtate of the fibres, the ſides of the cavities offer no reſiſtance to the newly arriving quantity of blood. Air very gently impelled, or the current of blood from the veins, is ſufficient to accompliſh the filling of the cavities.

After theſe general obſervations, we proceed to detail the motions of the individual parts ſeparately. A ſmall portion of the two cavæ, near the right auricle, is muſcular, and contracts on irritation. Theſe veſſels expel their blood by a ſtrong and manifeſt contraction into the auricle, and are then dilated by the current arriving from behind. The right auricle is diſtended by the blood received from the venæ cavæ, becomes turgid, and has a violet colour from the darkneſs of the contained fluid. It is contracted immediately after, expels its contents, and becomes pale again. The blood takes two courſes from this cavity; as there are no valves at the mouths of the veins, it flows back into the cavæ, and the reflux, which we have already ſpoken of in a former part of this article, extends to various lengths from the heart. In a living and healthy animal, the reflux is probably not conſiderable, as it is oppoſed by the weight of the column contained in the whole venous ſyſtem, and conſtantly preſſing forwards to the heart; but that it does take place occaſionally, even in the natural ſtate of the function, is obvious from the phenomena of ſtraining, when the veſſels of the head become diſtended with blood, in conſequence of the temporary obſtacle to the tranſmiſſion of the fluid through the lungs.

The ſecond and principal paſſage of the blood from the auricle, is into the ventricle, through the oſtium venoſum. The membranous valvular ring offers a circular open paſſage; its looſe edge yields to the current of the blood, and is preſſed by it againſt the ſides of the cavity, ſo as to enlarge the opening: the orifice of the pulmonary artery is at this time completely cloſed by the large diviſion of the tricuſpidal valve, which is placed againſt that aperture, ſo that the auricle has no effect on that veſſel. At the time when the contracted auricle expels its blood, the ventricle is looſe and relaxed; for if the latter were ſtill in its ſyſtole, its ſuperior ſtrength would prevent it from being diſtended by the weak auricle. The blood arrives therefore in the ventricle, fills and dilates it: and the meaſure of its diſtenſion amounts to the two or three ounces expelled from the auricle. The ventricle, excited by the preſence of the blood, which diſtends it, immediately contracts; and there are two paſſages by which the blood may eſcape; it may flow back into the auricle whence it has arrived, or it may be ſent into the pulmonary artery. The tricuſpidal valve prevents the firſt of theſe effects. The blood, impelled towards the axis of the cavity by the contraction of its ſides, carries the floating membranous valve in that direction, until it is brought to right angles with the axis, where it occupies the whole area of the oſtium venoſum. It cannot give way any further, or be driven into the auricle, becauſe the fleſhy columns, which are rendered ſhorter at the ſame time, retain it. The meaſure of the valve is ſuch, that when expanded it perfectly cloſes the communication, and prevents regurgitation from the ventricle into the auricle. The more forcibly any liquor is impelled in a direction contrary to the blood's courſe, the more completely is the opening ſhut. Haller conſtantly found waxen injection, thrown into the pulmonary artery, retained by this apparatus in the right ventricle. Yet the very elevation of the tricuſpidal valve muſt force back a certain portion of blood into the auricle. The circle of the anulus valvuloſus contains a certain portion of blood within the conical ſpace circumſcribed by its three diviſions, when the ventricle is diſtended. The action of the ventricle, by bringing the valve into the ſame plane with the oſtium venoſum, deſtroys this conical area, and puſhes the cone of blood contained in it into the auricle.

But the paſſage, which the blood principally takes, and which is ſuitable to the natural order of the functions, is through the arterial opening of the right ventricle, into the pulmonary artery. At the time that the elevation of the valve cloſes the auricular orifice, the large diviſion of the valve, which covers the mouth of the pulmonary artery, ſo long as its point is extended towards the apex of the heart, is removed from that ſituation, and leaves the entrance into the veſſel free. The blood eaſily finds its way through the ſigmoid valves, preſſing them againſt the ſide of the canal, and deſtroying their cavities; they obſtruct the mouths of the veſſel only in proportion to their thickneſs, which is a mere line, and even this impediment is avoided by their being received into the ſinuſes of the artery. The ventricle, being now empty, is relaxed, and paſſes into the ſtate of diaſtole.

The artery, diſtended by the blood impelled into its cavity from the ventricle, immediately afterwards recovers its former diameter; and muſt at this time repel the contained fluid towards the heart. But when it is urged in this direction, it meets with the open orifices of the valvular ſinuſes, enters and fills them, ſeparates thoſe floating folds from the ſides of the artery, and urges them towards its axis: when the three are fully expanded, they cloſe the opening completely, and entirely intercept the reflux of the blood towards the heart, as their ſize correſponds to the area of the veſſel. The tendinous fibres increaſe the ſtrength of theſe membranes, and enable them to ſuſtain better the impetus of the returning wave. In the dead ſubject they prevent the paſſage of waxen injection, or of air impelled towards the heart, and are ſaid by Haller to ſuſtain a weight of 63 pounds before they give way. When the aorta is tied in a living animal, it remains diſtended, as theſe valves prevent the blood from eſcaping into the heart.

After having paſſed through the pulmonary arteries and veins, the blood arrives at the left auricle: and the ſame obſervations may be made concerning thoſe veins, the left auricle, the mitral valve, the left ventricle, and the ſigmoid valves of the aorta, as we have already delivered concerning the correſponding organs on the right ſide. The two ſyſtems perfectly reſemble each other in their actions, and make two diſtinct hearts, between which the paſſage of the blood through the lungs intervenes.

Haller gives the following account of the ſucceſſion of motions in the different parts of the heart, and of the phenomena obſerved when the actions of theſe parts ceaſe. The venæ cavæ and pulmonary veins are contracted in the firſt point of time, and fill the auricles. The different parts of theſe cavities muſt be diſtended ſucceſſively; but the ſucceſſion is ſo rapid, not occupying more than a ſecond in a man who has the floweſt pulſe, that the whole auricle appears to be diſtended at once. In the ſecond portion of time theſe cavities expel their blood into the ventricles, acting perfectly together. In experiments on living animals their contraction is not always ſynchronous; but the irregularity generally occurs when the animal is exhauſted, and in the agonies of death; under circumſtances, which will not allow us to draw any inferences as to the natural order of the contractions. Diaſtole of the ventricles accompanies this contraction of the auricles. The latter is followed very quickly in a healthy animal by contraction of the ventricles, and this third period is the ſame with the firſt; that is, the

veins

veins fill the auricles at the ſame moment that the ventricles expel their contents into the arteries.

"The contractions of the heart become gradually weaker, as the animal languiſhes previouſly to death: they become at the ſame time more frequent, and hence the pulſe of perſons near their death is ſo ſmall and rapid, that it cannot be counted. Intervals are then obſerved between the contractions of the heart, and are indicated by intermiſſions of the pulſe, and irregularity in the reſpirations: theſe are of two or more ſeconds, or even a minute in living animals. I have obſerved in the incubated chick, as it grew weak, firſt ten, then ſix, four, and two pulſations in a minute. The left cavities of the heart then ceaſe to act, the ventricle firſt, and then the auricle. The pulſation of the right ventricle laſt longer; it contracts leſs frequently than the auricle, and gradually becomes quiet; irregular pulſation being ſtill occaſionally obſerved on the ſurface. The apex retains its irritability longer than any other part of the ventricles, and the ſeptum comes next in this reſpect. Motion generally continues for ſome time in the right auricle, after it has ceaſed in the ventricle, even for ſome hours. This part of the heart was therefore rightly called by Galen and Harvey the ultimum moriens. It may be excited from a ſtate of reſt into motion for the longeſt time, and the moſt quickly; and in this promptitude of action, when excited by throwing in warm water or air, or in any other way, it very much exceeds the ventricle. Its motion is very lively, and the pulſations are more frequent than thoſe of the left. In ſome caſes it has ceaſed to move firſt, before its own ventricle, and before the left cavities of the heart; but theſe inſtances are rare, and may be referred to an immoveable congeſtion of blood, or other cauſes foreign to the natural condition of the parts. Its contractions occur at longer intervals before they ceaſe altogether. That part of the venæ cavæ, which joins the auricle, always continues to pulſate for a long time, and ſometimes holds out even longer than the auricle. On the left ſide, the ventricle ceaſes before the auricle, and the pulmonary veins ſtill move after the other parts are at reſt. The latter have a ſynchronous motion with the venæ cavæ, ſo long as they continue to act; but when the motions grow feeble, the vena cava has the ſuperiority, both in the freqnency and the duration of the pulſations."

In no part of the animal frame do we obſerve ſo conſpicuouſly as in the heart the conſtant exertion, without any intermiſſion, from the earlieſt period of exiſtence to the moment of death, of ſo conſiderable a contractile power. As the important functions dependent on the circulation, ſuch as nutrition, ſecretion, exhalation, and the expoſure of the blood to the air can only be carried on while the heart's motions are continued, we readily underſtand why that is the part firſt obſerved to move in the embryo, and why the uninterrupted continuance of its action is neceſſary to the ſupport of life: hence we ſhall think that Haller has hardly exaggerated its importance in the following paſſage of his Elementa Phyſiologiæ. "Denique ſæpe pullum contemplatus, qui ovo incubato continetur, comparavi miram vivacitatem et igneam vim corculi, ſub finem ſecundi diei duriuſculi, firmi et terminati, cum pigro et diffluente muco, quo reliquum corpuſculum conſtat, et cum ſumma mollitie arteriolarum, quæ in eo muco artuum, viſcerumve, aut in cerebri aqua cogitari poſſunt; facillimum enim Harveii experimentum repetii, quo languens pulli corculum ſtimulo, guttave aquæ calidæ, ad celerrimum inque omnes arterias etiam membranarum propagatum motum ſuſcitatur, cum nullo alio modo nulla irritatione arteriarum, viſcerumque quidquam vel eminus ſimile aut minimum motum excitare liceat. Sed etiam in homine, aut animale calido, naturam ſumme irritabilem cordis, ignaviæ vis contractilis arteriarum, et perfectæ in frigidis beſtiis inertiæ, et immobili corpori reliquarum partium omnium oppoſui. Aptitudinem denique ad motum, et tenacitatem vitæ expendi, quæ in corde eſt, et quam, præter inteſtina, nulla alia pars machinæ animalis adtingit. His omnibus conſideratis præcipuam, et parum ab unica diſtantem, motus omnis in corpore ſcaturiginem in corde reperio." Lib. 4. ſect. 4. § 28.

In the article Death, we have mentioned that the functions of the brain, the heart, and the lungs, are ſo connected together, that the interruption of either is followed by that of the others; and we have given a general ſketch of the manner in which that effect is produced. The details of this ſubject belong to the preſent article, that on the Lung, and on the Nervous *ſyſtem*, and are derived from the "Recerches Phyſiologiques ſur la Vie et la Mort" of Bichat.

In conſidering how the brain can be influenced by the heart, this author firſt eſtabliſhes the point, that it cannot be by means of the nerves: the ſection, or ligature, of thoſe organs (the cardiac nerves) does not influence the functions of the brain; and they only modify indirectly the action of the heart. Conſequently the veſſels muſt be the excluſive agents of the heart's influence on the brain.

The heart, which propels the red blood, affects the brain, in the firſt place, by the motion which it communicates to the organ. If the arrival of this fluid be completely intercepted, the motion of the brain ceaſes, and life is extinguiſhed when the carotids alone are tied, the vertebral arteries ſtill keep up the movement, and no ill effect is produced. Compreſſion acts by preventing the organ from obeying the impulſe communicated to it by the arteries. The motion, which is very obſcure in the other viſcera, is very conſiderable in the encephalon. All the large arteries placed at its baſis, and between it and the bony parietes of the cranium, experience at the time of their pulſation a reſiſtance from the latter, which throws the whole of the motion on the brain, ſo that it is elevated, as tumours are, when ſituated over a conſiderable artery, ſupported on its oppoſite ſurface by a reſiſting plane. If water be thrown gently into the carotid, the animal is not injured: but if it be puſhed in impetuouſly, ſo as to derange the ordinary motions of the organ, the action of the brain is diſturbed, and various effects are produced even as far as death, according to the violence employed. On the other hand, if the brain be expoſed and an artery opened, the motion of the organ is diminiſhed in proportion as the blood arrives at it with leſs force, and is then entirely loſt.

The ſecond mode of influence, in this caſe, is derived from the nature of the fluid which the heart of red blood ſends to the brain. We refer on this ſubject to Lung, as it is in that organ that the changes are produced in the blood, which is conveyed through the heart without any alteration.

The heart of black blood cannot immediately influence the brain. A ſpecies of death, which has generally been referred to this part of the organ, *viz.* by the injection of air into the veins, is explained by Bichat as ariſing in the brain. When air is introduced into the veins, even in ſmall quantity, the heart's contractions are accelerated, the animal is agitated, howls as if ſuffering pain, is ſeized with convulſive motions, loſes the powers of ſenſation and voluntary motion, and ſoon ceaſes to exiſt entirely. Bichat adduces the following proofs that the brain is firſt affected in this caſe. The heart ſtill beats after the animal life is ſuſpended. Injection of air into the carotid produces analogous effects, with the exception of the acceleration of the heart's action. In animals killed by this proceſs, the left cavities of the heart, as well as the right, are full of frothy blood, and the

arteries and veins of the brain contain the ſame kind of fluid; ſo that the ſimple contact of air with the right cavities is not ſuddenly fatal. If the brain ceaſed to act from a diſcontinuance of the heart's contractions, death would enſue, as in ſyncope, and in copious arterial hæmorrhages; *i. e.* without any well marked convulſive motions. In this inſtance, on the contrary, the convulſions are often extremely violent, and announce irritation of the brain, which can be produced only through the medium of the air which is ſent to that organ with the blood.

The functions of the lungs conſiſt in producing a certain change in the blood received from the right ſide of the heart: the latter, therefore, influences the former moſt powerfully, as it ſupplies the blood in which theſe changes are produced; and, conſequently, the interruption of its action, by cutting off that ſupply, puts a ſtop to the chemical phenomena of the lungs. The heart of red blood, by acting on the brain, affects the muſcles concerned in reſpiration; and thereby influences the mechanical phænomena of that function.

The heart has no leſs influence over the organs of the body in general, than over the brain and lungs. By the motion which it communicates to the former, that is maintained in a ſtate of activity, and enabled to receive ſenſations from external bodies, and to produce voluntary motions; hence the latter functions are immediately ſtopped when the heart of red blood ceaſes to act. The ceſſation is ſudden, as when the encephalon has experienced a violent commotion annihilating its action. In this manner a wound of the heart, or the burſting of an aneuriſm, ſuddenly ſuſpend our relations to external objects. The organs of ſenſation and voluntary motion are alſo influenced by the heart of red blood in another manner, which is common to them with thoſe of the organic life: they experience an habitual agitation, an inteſtine impulſe, produced by the diviſion of the arteries in their ſubſtance, and neceſſary to the execution of their functions. The functions of the organic life, ſuch as nutrition, exhalation, &c. receive all their materials from the heart of red blood: hence they muſt be ſoon ſuſpended after that ceaſes to act. In theſe conſiderations we do not take into account the nature of the blood ſent to the organs, whether it be black or red; that circumſtance belongs to the account of the pulmonary functions.

"Whenever," ſays Bichat, "the heart ceaſes to act, general death comes on in the following manner; the action of the brain is annihilated at firſt for want of excitation: hence the ſenſations, locomotion, and the voice, which are under the immediate influence of the brain, are interrupted. Moreover, the organs of theſe functions would ceaſe to act from want of excitation by the blood, even if the brain were unaffected, and could ſtill exert its ordinary influence upon them. All the animal life is ſuddenly ſuſpended, and, at the inſtant of the heart's death, man ceaſes to exiſt with relation to ſurrounding objects. The interruption of the organic life, which has commenced with the circulation, goes on at the ſame time in the function of reſpiration. No more mechanical phenomena in the lungs, after the brain has ceaſed to act; becauſe the reſpiratory muſcles are under the influence of the latter organ. No more chemical phenomena, as ſoon as the heart can neither receive nor propel the materials neceſſary for their developement; ſo that in injuries of the heart, the latter phenomena are interrupted directly, while the former ceaſe indirectly, and through the medium of the brain. General death then goes on gradually by the interruption of the ſecretions, the exhalations and nutrition. The latter ceaſes firſt in thoſe parts which receive blood habitually; becauſe the excitation, produced by this fluid, and neceſſary for its ſupport, ceaſes; it ſtops ſubſequently in the white organs, which are leſs ſubject to the influence of the heart.

"In this ſucceſſive termination of the phenomena of internal life, its powers ſtill ſubſiſt ſome time after the functions have ceaſed; the organic ſenſibility, and the organic contractilities ſurvive the phenomena of digeſtion, nutrition, &c. How does it happen that the vital powers ſtill continue for ſome time in the internal life, while thoſe of the external are ſuddenly extinguiſhed? Becauſe the powers of feeling and moving organically do not ſuppoſe the exiſtence of a common centre; while, on the contrary, the influence of the brain is neceſſary in the ſenſations and voluntary motions.

"This is the order in which the phenomena of general death ſucceed each other, when they depend on the burſting of an aneuriſm, on a wound of the heart, or any large blood-veſſel, or on any cauſe affecting this organ. We die in the ſame manner from any ſtrong mental affections. Where an individual expires at the news of an event which tranſports him with joy, or plunges him into deſpair, at the ſight of an object which inſpires him with terror, or of a rival, whoſe ſucceſs irritates his jealouſy, the heart ceaſes firſt to act; and its death is followed by that of the other organs." The author goes on to ſhew that the heart is the part affected in the caſe of ſyncope; and that the brain is influenced in a ſecondary manner. The faintings produced by lively mental emotions are analogous, in all their phenomena, to thoſe cauſed by organic affections of the heart, which obviouſly owe their origin to this organ. Theſe mental cauſes very often give riſe to diſeaſes of the heart, but not to thoſe of the brain. The brain has no direct influence on the circulation; there is no reciprocity between them. Affections of the former do not produce analogous affections of the latter; while the latter modify the former eſſentially in the manner already deſcribed. If the influence of the paſſions be not carried ſo far as entirely to ſuſpend the circulation, and conſequently to produce ſyncope, palpitations, and other irregular motions, frequently reſult from it. Theſe ſecondary effects are always found in the heart, and never in the brain: here the affected organ is readily diſtinguiſhed, becauſe a ſingle part is acted on, and all are not troubled as in ſyncope.

"In ſyncope, aſphyxia, and apoplexy, general death begins reſpectively in the heart, lungs, and brain. In that which ends diſeaſe, the circulation, reſpiration, or the cerebral action ceaſe; and the interruption of the other functions is a neceſſary conſequence. The heart is but rarely the firſt part of which the action ſtops: this, however, happens ſometimes, as after long continued ſevere pains, extenſive ſuppurations, hæmorrhages, dropſies, certain fevers, &c. where ſyncope has appeared at certain intervals, and a more violent attack carries the patient off. Whatever part may have been affected in ſuch inſtances, the phenomena of death begin in the heart, and ſucceed each other in the order we have already explained, as occurring in the ſudden deaths which begin with a leſion of that organ.

"In other caſes the functions of the heart do not ceaſe till after thoſe of other parts: it is the ultimum moriens. In general, the cheſt becomes affected much more commonly in the various morbid affections, whether chronic or acute, and the commencement of death in the lungs is more frequent than in the heart or brain. When diſeaſe is ended by ſyncope, the lungs are conſtantly found almoſt entirely empty in the dead ſubject; they are never loaded with blood. If no diſeaſe exiſted in them previouſly, they are collapſed, do not fill the cavity of the cheſt, and poſſeſs their natural colour. A ſimple reaſon may be aſſigned for this anatomical fact. The circulation being ſuddenly interrupted, inſtead of gradually

dually weakened, there is no time for the pulmonary veſſels to become diſtended, as when general death begins in the lung, or in the brain. I have already collected numerous inſtances of perſons who have died by ſyncope, in whom the lungs were found in this empty ſtate. In general, whenever death has begun in the heart or large veſſels, and has been ſudden, the emptineſs of the pulmonary veſſels may be regarded as a general phenomenon; it is ſeen in deaths from the hæmorrhage of large wounds, from aneuriſmal ruptures, violent emotions, &c. I have obſerved it in the bodies of perſons guillotined; and it is equally viſible in animals ſlaughtered for food."

The influence of the lungs on the heart will be conſidered under LUNG.

The heart's action is ſubject to that of the brain, ſo that the ceſſation of the latter interrupts the former. In explaining how this takes place, Bichat obſerves that "moſt phyſicians ſpeak too vaguely of nervous influence, and do not determine with ſufficient preciſion its extent and limits with reſpect to the various organs. Every thing concurs to prove that the brain exerts no immediate influence on the heart, while the latter preſerves the former in a ſtate of dependance by the motion which it communicates. This aſſertion is not new: all good phyſiologiſts admit it; but as ſeveral medical opinions proceed on an oppoſite aſſumption, I ſhall demonſtrate it by ſome obſervations and experiments. 1ſt. Any conſiderable irritation of the brain, produced either by a ſplinter of bone, by blood, or by any other cauſe, almoſt always cauſes general or partial convulſions of the voluntary muſcles: the muſcles of the organic life, and particularly the heart, are not affected. 2dly. Compreſſion of the brain produces paralyſis of the voluntary muſcles; but if thoſe of the cheſt be not affected, the heart's action is not diminiſhed. 3dly. Opium and wine, in a certain doſe, have a temporary effect in diminiſhing the cerebral energy, and rendering it leſs capable of executing the functions of the animal life: the heart continues to act as uſual, and ſometimes its contractions are increaſed. 4thly. Palpitations, and various irregular motions of the heart, are not derived from the brain, which is in a perfectly natural ſtate. 5thly. The numerous phemomena of apoplexy, epilepſy, catalepſy, narcotiſm, concuſſion, &c. which have their chief ſource in the brain, throw great light on the independance of the heart's action. 6thly. All organs ſubject to the direct influence of the brain are thereby voluntary. I believe that, in ſpite of Stahl's obſervation, nobody continues to rank the heart among organs of that deſcription. What would be the tenure of life, if we could ſuſpend at pleaſure the action of the organ which is its main ſource? Death might be then brought on by a ſimple act of volition. Thus mere obſervation would authorize us in inferring, without much fear of error, that the ceſſation of the heart's action, conſequent on the interruption of the cerebral functions, does not ariſe from any immediate influence. But we can give a further ſupport to this fundamental poſition of phyſiology and pathology by direct experiments. 1ſt. By irritating the brain in a living animal by various mechanical or chemical agents, or by compreſſing it, various effects are produced on the organs of the animal life; but the functions of the heart are unimpaired, ſo long as the pectoral muſcles are not paralyſed. 2dly. The reſult of ſimilar experiments on the ſpinal marrow laid bare in the neck, is perfectly analogous. 3dly. The heart's action is not accelerated by irritating the nerves of the eighth pair; nor is it arreſted by dividing the trunks of thoſe nerves. Thoſe, who perform ſuch experiments, muſt carefully diſtinguiſh the effects of the various feelings produced in the animal by his ſufferings from the reſult of the irritation or ſection of the nerves. 4thly. The ſame trials on the cardiac branches of the great ſympathetic have exactly the ſame effect. Galvanic experiments, performed with the moſt ſcrupulous attention, have confirmed the inferences which may be drawn from the preceding account. I armed the brain and medulla ſpinalis of frogs with lead, and placed a plate of zinc in contact with the heart and ſome voluntary muſcles; on forming the communication the latter were thrown into motion, while the former was not affected. In ſubjects, who had been guillotined, and in whom galvaniſm produced contractions of the voluntary muſcles, I could not diſcern the leaſt motion of the heart, when the ſpinal marrow, or the cardiac branches of the ganglia or the par vagum on one ſide, and the heart on the other were armed, and the communication made between them. Yet mechanical irritation cauſed contraction of the heart. The ſame experiments on dogs and guinea-pigs, in which the brain alſo was tried, had the ſame reſult: when the communication was made between the two metals, it neither accelerated the heart's motion if it ſtill continued, nor reanimated it if it had ceaſed. Experiments on the cardiac nerves and the heart of two living dogs produced no very apparent motions.

Humboldt ſtates, that when the heart is detached ſuddenly, ſo as to leave ſome of its nerves inſulated, contractions may be produced by arming them with one metal, and touching this with another. I have tried this unſucceſsfully many times: yet it appeared to ſucceed once. The only certain method of producing galvanic phenomena in the heart, with efficacy and clearneſs, is to remove the organ in a warm-blooded animal; to put it in contact with two metals at two different points, and then make the communication. But this does not bear at all on the point in queſtion, *viz.* whether the brain exerts any direct influence on the heart.

I have repeated all theſe experiments on galvaniſm many times, and with the moſt minute precautions: yet I do not pretend to throw any doubt on the different reſults which ſome celebrated enquirers have obtained. Every one knows how variable are the effects of experiments on the vital powers. Moreover, if the reports of other experimenters be received, it will be impoſſible to overlook the ſtriking difference between the muſcles of the animal and organic lives in reſpect to galvanic excitation. An excellent method of obſerving this is, when we are trying what effect is produced on the heart or inteſtines, to uſe alſo ſome voluntary muſcles, and thus to eſtabliſh a parallel between the two kinds of organs.

Suppoſe, for a moment, that the galvanic influence had juſt the ſame effects on both kinds of muſcles: what would this prove, except that the galvanic phenomena follow laws completely oppoſite to thoſe of the appearances reſulting from common irritation of theſe parts?

Since then the ceſſation of the heart's action, conſequent on great leſions of the brain, is not direct, although it comes on immediately, there muſt be an intermediate organ, the interruption of whoſe action is the proximate cauſe ſought. This organ is the lung: and the following is the ſucceſſion of the phenomena. 1. Interruption of the action of the brain; 2, paralyſis of all the voluntary muſcles, and conſequently of the diaphragm and intercoſtals; 3, ſuſpenſion of the mechanical phenomena of reſpiration; 4, of the chemical phenomena; 5, arrival of black blood at the fibres of the heart; 6, debilitation of thoſe fibres and ceſſation of action.

The death, which ſucceeds ſerious injuries of the brain, has therefore conſiderable analogy to the different aſphyxiæ:

it is only more prompt, for the reaſons which I ſhall adduce. The following experiments prove inconteſtibly that the phenomena of death in this caſe are connected in the order juſt deſcribed.

1. I have conſtantly found black blood in the red-blooded ſyſtem of all animals killed by concuſſion or compreſſion of the brain: their heart is livid, and all the ſurfaces are coloured nearly as in aſphyxia.

2. I have opened the carotid in a dog, and red blood immediately flowed: the artery was then tied, and the animal killed by a violent blow on the occiput. The animal life was inſtantaneouſly annihilated; all voluntary motion ceaſed; the mechanical, and conſequently the chemical phenomena of reſpiration were arreſted. When the artery was now ſet at liberty, it poured out black blood with a feeble jet; this gradually diminiſhed, and the motion of the heart ceaſed after a few minutes.

3. I have always obtained a ſimilar reſult by opening an artery in various animals, and killing them afterwards, either by a ſection of the medulla ſpinalis, between the firſt vertebra and the occiput, by compreſſing ſtrongly the brain previouſly laid bare, or by the deſtruction of that organ. Animals die in the ſame manner when noxious matters are injected into the carotid.

4. The preceding experiments explain the blackneſs of the blood flowing from the arteries, when they are opened after an animal has been knocked down as in the ordinary mode of ſlaughtering. If the blow on the head be very violent, the blood runs out quite of the venous colour: if it ſhould only weaken the diaphragm and intercoſtals, the colour of the blood is not ſo deep.

The ſtate of reſpiration, which may be affected by various cauſes during a copious hæmorrhage, produces conſiderable variations in the colour of the diſcharged blood: when the breathing goes on naturally, the arterial blood is red, and it has a browniſh tint when that function is impeded.

If any individual has been able, by a voluntary exertion, to ſuſpend the pulſation of the heart, this fact does not prove, as the diſciples of Stahl aſſerted, the influence of the ſoul on the motions of the organic life, but merely on the mechanical phenomena of reſpiration, which, as well as the chemical phenomena, muſt have been previouſly ſtopped. In cold blooded animals the death of the heart does not follow that of the brain ſo rapidly. Circulation will continue for a conſiderable time in the frog and ſalamander, after the the brain has been removed, as I have aſcertained by repeated experiments. This will be explained by the well-known fact that reſpiration may be ſuſpended for a long time in theſe animals, without the motions of the heart being ſtopped. In fact, ſince the heart's action, according to our explanation, ceaſes, after that of the brain is interrupted, only becauſe the lung dies previouſly, there ought to exiſt, between the death of the brain and that of the heart, an interval equal to the time during which reſpiration may be ſuſpended in the natural ſtate.

HEART *of Stone*, in *Mining*, is the name, in the neighbourhood of Bath, particularly 3½ miles E. of the town at Warley Rocks, for the caſt of a ſhell reſembling the genus Mya, of which, as well as the caſt, figures are given in Walcot's "Petrifactions," figs. 5 and 16. In other ſituations, where ſtones are ſubject to hard places in them, frequently of a different colour from the maſs, they are called hearts of the ſtone, or cores.

HEARTH, Focus. See FIRE, CHIMNEY, &c.

HEARTH-*money*. See CHIMNEY-*money*.

HEARTH-*ſtone*. See FIRE-*ſtone*.

HEARTH, in *Mining*, is applied, in Derbyſhire, to the ancient lead-ſmelting furnaces, which were like a blackſmith's forge on a large ſcale, blown by bellows worked by water. Since cupolas or low reverberatory furnaces have been generally adopted, a few only of the ancient hearths have been retained, and called ſlag-hearths, for re-melting the black or drawn ſlag of the cupolas. See Mr. Farey's Report on Derbyſhire. The lining of the iron furnaces, or that in which the moſt intenſe heat is excited, is called the hearth, and is compoſed of large blocks of *Fire-ſtone*. See that article.

HEAT is a term uſed by ſome writers to ſignify the cauſe which produces in us the ſenſation of warmth. In this ſenſe it is ſynonymous with *fire* and *caloric*. It is alſo uſed to denote the ſenſation itſelf of warmth, in which caſe it is oppoſed to *cold*.

Heat, in the firſt ſenſe, is now commonly conceived to be an extremely ſubtile and elaſtic fluid, ſtrongly attracted by other matter, and of inſenſible gravity; but ſome ſuppoſe it to be merely a property of matter, and to conſiſt in a ſort of vibration of its ultimate particles. Theſe different opinions will be found diſcuſſed, and ſome of the general properties of heat pointed out, under the head CALORIC.

Heat is unqueſtiouably one of the moſt important agents employed by nature in forming the conſtitution of bodies, and in producing that unceaſing change obſervable in the animal, the vegetable, and the mineral kingdoms. There is ſcarcely any department of phyſical ſcience in which the nature and properties of heat do not in ſome way enter into our conſideration. Of courſe this ſubject demands an extenſive developement, and many of its branches muſt be diſplayed under their reſpective heads. See CAPACITY *for Heat*, COLD, COMBUSTION, EXCITATION *of Heat*, EXPANSION, FIRE, and TEMPERATURE.

On ſome of the above articles we ſhall now make a few additional obſervations, partly in conſequence of recent diſcoveries;

diſcoveries; and next advert to the following ſubdiviſions, namely, *Animal* HEAT, CALORIMETER, *Communication of* HEAT, *Free* or *Senſible* HEAT, and *Latent* HEAT.

Capacity for HEAT, or *Specific* HEAT.—That bodies of the ſame weight and temperature contain unequal quantities of heat has been ſhewn under the heads CAPACITY and COLD. It is of importance to aſcertain the ſpecific heats of different bodies, or the ratios of the quantities of heat neceſſary to raiſe them a given interval of temperature. This has been made the ſubject of experimental inquiry by ſeveral authors, as Black, Irvine, Crawford, Gadolin, Wilcke, Lavoiſier, Meyer, Leſlie, and Dalton. The following table of the capacities of certain bodies is derived from their reſults, the more objectionable ones being omitted.

TABLE of the ſpecific Heats of various Bodies.

	Equal Weights.	Equal Bulks.
Gaſes.		
Hydrogen	21.40*	.002
Oxygen	4.75*	.006
Common air	1.79*	.002
Carbonic acid	1.05*	.002
Azotic gas	.79*	.001
Aqueous vapour	1.55*	.001
Liquids.		
Water	1.00	1.00
Arterial blood	1.03*	
Milk (1.026 ſp. gr.)	.98	1.00
Carbonate of ammonia (1.035)	.95	.98
Carbonate of potaſh (1.30)	.75	.98
Solution of ammonia (.948)	1.03	.98
Common vinegar (1.02)	.92	.94
Venous blood	.89*	
Solut. com. ſalt (1.197)	.78	.93
Solution of ſugar (1.17)	.77	.90
Nitric acid (1.20)	.76	.96
Nitric acid (1.30)	.68	.88
Nitric acid (1.36)	.63	.85
Nitrate of lime (1.40)	.62	.87
Sulph. acid and water equal bulks	.52	.80
Muriatic acid (1.153)	.60	.70
Acetic acid (1.056)	.66	.70
Sulphuric acid (1.844)	.35	.65
Alcohol (.85)	.76	.65
Ditto (.817)	.70	.57
Sulphuric ether (.76)	.66	.50
Spermaceti oil (.87)	.52	.45
Mercury	.04	.55
Solids.		
Ice	.90?	.83?
Dried woods, and other vegetable ſubſtances, from .45 to	.65	
Quicklime	.30	
Pit-coal (1.27)	.28	.36
Charcoal	.26*	
Chalk	.27	.67
Hydrate of lime	.25	
Flint glaſs (2.87)	.19	.55
Muriate of ſoda	.23	
Sulphur	.19	
Iron	.13	1.00
Braſs	.11	.97
Copper	.11	.98
Nickel	.10	.78
Zinc	.10	.69
Silver	.08	.84
Tin	.07	.51
Antimony	.06	.40
Gold	.05	.97
Lead	.04	.45
Biſmuth	.04	.40
Oxyds of the metals ſurpaſs the metals themſelves, according to Crawford.		

Thoſe marked * are entirely on Crawford's authority. There is reaſon to doubt of the accuracy of his reſults reſpecting the gaſes, from the extremely great difficulties which they preſent in regard to this inquiry. Mr. Dalton has given a theory or hypotheſis for the ſpecific heat of gaſes in general, which as ſuch merits attention. It may be ſeen under the article GAS. The manner in which the ſpecific heats above given are obtained may be ſeen in the articles CAPACITY and COLD, and in the works of the above mentioned authors. It is believed that the capacity of bodies is not quite permanent at all temperatures, even while they retain their form, though the variation of the capacity is probably ſmall in general; it is ſuppoſed to increaſe with the temperature. Mr. Dalton ſeems to think the capacity of boiling water may be to that of water at the freezing temperature, as 102, or perhaps 105, to 100. See his New Syſtem of Chemiſtry, p. 51.

COLD.—To the reſults of experiments already related, which have been made with a view to aſcertain the point of *abſolute cold*, may be added thoſe of Mr. Dalton, given in a ſection on the natural zero of temperature, or abſolute privation of heat.

				Zero below 32° Fahrenheit.
From a mixture of	5.77	ſulph. acid and	1 water, by weight	6400°
	1.6		1	4150
	1		2	6000
	3	lime	1	4260
	7	nitric acid	1 lime	11000
From the combuſtion of		hydrogen		5400
		phoſphorus		5400
		charcoal		6000
		oil, wax, and tallow		6900
		ether		6000

The

The mean of all theſe is 6150°. From this Mr. Dalton concludes the zero to be about 6000° below the temperature of freezing water; but he allows that the differences in theſe reſults, though much leſs than had been made before, are ſtill ſuch as to throw ſome doubt upon the concluſion, and to require further inveſtigation.

Combustion, *heat produced by*.—The quantity of heat liberated or detached during combuſtion, forms an important ſubject of inquiry. The calorimeter, an inſtrument invented by Lavoiſier and Meuſnier, was intended for this purpoſe; and the reſults of Lavoiſier and La Place, derived from this inſtrument, are detailed in the Elements of Chemiſtry, publiſhed by the former. Dr. Crawford has inveſtigated this ſubject with his uſual ingenuity, and without the aid of the calorimeter, the reſults of which are given in his Eſſay on Animal Heat and Combuſtion. More recently, Mr. Dalton has added ſomething to the knowledge on this ſubject by a ſeries of experiments published in his chemiſtry. The quantity of heat diſengaged by the combuſtion of a given weight of any combuſtible has been eſtimated by the number of pounds of ice which it would melt, this ſort of meaſure being adopted through the uſe of the calorimeter. For the manner of executing the experiments relating to this ſubject, we muſt refer to the works above mentioned. The following are the reſults obtained by the different authors.

	According to Lavoiſier.	According to Crawford.
1 lb. of hydrogen, by combuſtion, melts	295 lbs. ice.	480 lbs. ice.
—— phoſphorus —— —— ——	100 ——	—— ——
—— charcoal —— —— ——	96.5 ——	69 ——
—— wax —— —— ——	133 ——	97 ——
—— oil —— —— ——	148 ——	89 ——

Dalton's Reſults on Combuſtion are as follow.

1 lb.	hydrogen	takes	7	lbs.	oxygen;	produce	8 lbs.	water;
——	carbur. hyd.	——	4	—	——	——	5 —	wat. and car. acid.
——	olefiant gas	——	3.5	—	——	——	4.5 —	——
——	carb. oxyd	——	.58	—	——	——	1.58 —	carb. acid.
——	oil, wax, and tallow	——	3.5	—	——	——	4.5 —	wat. and car. acid.
——	oil of turp.	——	——	—	——	——	—— —	——
——	alcohol	——	——	—	——	——	—— —	——
——	ether	——	3	—	——	——	4 —	——
——	phoſphorus	——	1.5	—	——	——	2.5 —	phoſ. acid.
——	charcoal	——	2.8	—	——	——	3.8 —	carb. acid.
——	ſulphur	——	——	—	——	——	— —	ſulphurous acid
——	camphor	——	——	—	——	——	— —	wat. and car. acid.
——	caoutchouc	——	——	—	——	——	— —	——

melts	320	lbs.	ice.
——	85	—	—
——	88	—	—
——	25	—	—
——	104	—	—
——	60	—	—
——	58	—	—
——	62	—	—
——	60	—	—
——	40	—	—
——	20	—	—
——	70	—	—
——	42	—	—

This author adds, that the heat given out by the combuſtion of 1lb. of charcoal, and perhaps alſo of pitcoal, is ſufficient (if there was no loſs) to raiſe 45 or 50lbs. of water from the freezing to the boiling temperature, or it is ſufficient to convert 7 or 8lbs. of water into ſteam.

Expansion. We have before given the expanſion of ſolids, of liquids, and of aeriform fluids by heat, from which it appears that if the common thermometer be deemed an accurate meaſure of temperature, there is nothing like a general law of expanſion to be found either applicable to ſolids or to fluids. Few experiments have been made on the progreſſive expanſion of ſolids; they are believed to expand nearly in a uniform manner. De Luc has ſhewn that liquids expand increaſingly with the temperature. Gay Luſſac contends that air expands uniformly, or in arithmetical progreſſion with the temperature from 32° to 212°; but in this reſpect he is oppoſed by every one elſe. Dalton maintains that the expanſion of pure liquids, ſuch as mercury and water, is in proportion, not to the temperature, but to the ſquare of the temperature reckoned from the freezing point, or rather the point of maximum denſity of the liquids; conſequently he concludes the common equal diviſion of the thermometer to be erroneous. He aſſerts that a thermometer of water and one of mercury, graduated upon the above principle, will agree with each other; alſo that the expanſion of air will be in geometrical progreſſion to the degrees of ſuch thermometer; that the expanſive force of ſteam over water will likewiſe conſtitute a geometrical progreſſion; and laſtly, that the refrigeration of heated bodies will obſerve a ſimilar law; that is, the decreaſe in temperature will be geometrical for equal intervals of time, provided the temperature be eſtimated by a thermometer of the new graduation. Theſe very important concluſions are derived from experience, and have not yet been controverted. (See Temperature and Steam). He determines the maximum denſity of water to be at 36°, and not at 40°, as has been lately believed, and that it expands equally by the addition or abſtraction of temperature, from that point till congelation takes place.

Calorimeter was the name given to an inſtrument invented by Lavoiſier and La Place, and deſcribed in the Elements of Chemiſtry of the former, and in the Memoirs of the Academy for 1780. The calorimeter is repreſented in plate 6. of the Elements (tranſlated by Kerr). It is ſhewn in perſpective at *fig.* 1, and its interior ſtructure is engraved at *figs.* 2 and 3, the former being a horizontal and the latter a perpendicular ſection. Its capacity or cavity is divided into three parts, which, for better diſtinction, may be named the interior, middle, and external cavities. The interior cavity *f f f f*, *fig.* 4, into which the ſubſtances ſubmitted to

experiment

experiment are put, is compoſed of a grating or cage, of iron wire, ſupported by ſeveral iron bars; its opening or mouth L M, is covered by the lid H G, which is compoſed of the ſame materials. The middle cavity *b b b b*, *figs.* 2 and 3, is intended to contain the ice which ſurrounds the interior cavity, and which is intended to be melted by the caloric of the ſubſtances employed in the experiment. The ice is ſupported by the grate *m m* at the bottom of the cavity, under which is placed the ſieve *n n*. Theſe two are repreſented ſeparately in *figs.* 5 and 6. In proportion as the ice contained in the middle cavity is melted by the caloric diſengaged from the body, placed in the interior cavity, the water runs through the grate and ſieve, and falls through the conical funnel *c c d*, *fig.* 3, and the tube *x y*, into the receiver F, *fig.* 1. This water may be retained or let out at pleaſure, by means of the ſtop-cock *u*. The external cavity *a a a a*, *figs.* 2 and 3, is filled with ice, to prevent any effect upon the ice in the middle cavity from the heat of the ſurrounding air, and the water produced from it is carried off through the pipe S T, which ſhuts by means of the ſtop-cock *r*. The whole machine is covered by the lid F F, *fig.* 7, which is made of tin, and painted with oil colour, to prevent ruſt. When this machine is employed, the middle cavity *b b b b*, *figs.* 2 and 3, the lid G H, *fig.* 4, of the interior cavity, the external cavity *a a a a*, *figs.* 2 and 3, and the general lid F F, *fig.* 7, are all filled with pounded ice, well rammed, ſo that no void ſpaces remain, and the ice of the middle cavity is allowed to drain. The machine is then opened, and the ſubſtance ſubmitted to experiment being placed in the interior cavity, it is inſtantly cloſed. After waiting till the included body is completely cooled to the freezing point, and the whole melted ice has drained from the middle cavity, the water collected in the veſſel F, *fig.* 1, is accurately weighed. The weight of the water produced during the experiment, is an exact meaſure of the caloric diſengaged during the cooling of the included body, as the heat diſengaged is evidently ſpent in converting part of the interior ice into water, at the rate of 135° or 140° for each pound of water. That is, as much heat is required to melt a pound of ice as would raiſe a pound of water 140°. The ſubſtances to be operated upon are placed in the thin iron bucket, *fig.* 8, the cover of which has an opening fitted with a cork, into which a ſmall thermometer is fixed, or ſometimes a matraſs, *fig.* 10, with a ſimilar thermometer, which ſtands in the interior cavity upon the ſmall cylindrical ſupport R S, *fig.* 10. Care muſt be taken that no communication ſubſiſt between the middle and external cavities of the calorimeter; leſt the ice melted by the external air ſhould mix with that melted by the ſubject of the experiment. The ice employed ſhould not be under 32°, and the air ſhould be ſomewhat above 32°, in the place where the experiment is performed. When the inſtrument is to be applied to find the heat given off by animals, and by combuſtion, &c. two ſmall tubes are neceſſary to be connected with the inſtrument, the one to convey freſh air into the interior, and the other to take off the uſed air. When the capacities of bodies for heat are to be found by this inſtrument, the heated ſolid or liquid (due allowance being made for the containing veſſel) is placed in the interior capacity of the calorimeter, and ſuffered to remain till it attains the temperature of 32°; then the weight of the melted ice being found $= w$, and the weight of the body being denoted by s, and the number of degrees of temperature it is reduced by n, we have this formula; $\frac{140\,w}{n\,s}$ = the capacity of the body, that of water being unity. For example, Lavoiſier and La Place found 7.7lbs. of iron heated to 207°.5, melted 1.11lbs. of ice; here $w = 1.11$, $s = 7.7$, and $n = 207°.5 - 32° = 175°.5$; whence $\frac{140 \times 1.11}{175.5 \times 7.7}$ = .115 for the ſpecific heat of iron.

The calorimeter, though a promiſing inſtrument in theory, has not anſwered expectation in practice; it is liable to ſome uncertainties, particularly with regard to the quantity of water which may remain adhering to the pounded ice of the inner veſſel on the principle of capillary attraction, and to the obſtruction of its deſcent by an agglutination of the fragments of ice in the lower part of the veſſel. See Wedgwood, Philoſ. Tranſ. vol. 74.

Communication of HEAT, including its *radiation*, *refraction*, *reflection*, &c.—The communication of heat from one body to another, or from one part to another of the ſame body, or the motion of heat in general, forms one of its moſt intereſting characters. Many important facts have recently been aſcertained on this ſubject by count Rumford, Dr. Herſchel, and Mr. Leſlie. That rays of heat come from the ſun along with the rays of light, but capable of being ſeparated from them by the refraction of a priſm, has been ſhewn by Dr. Herſchel. (See REFRACTION.) He has ſhewn that the rays of heat are leſs refrangible than thoſe of light and that by a priſm they are refracted to the red end of the ſpectrum principally, and are moſt denſe and powerful ſomewhat beyond the red extremity. The velocity of the ſolar heat is probably much the ſame as that of light. This heat is ſubject to reflection, as is evinced by placing a body on the focus of a concave mirror expoſed to the ſun. It is remarkable that culinary heat is equally ſubject to reflection as ſolar heat, but not to refraction. Mr. Leſlie is of opinion, that the velocity of reflected heat is the ſame as that of ſound, and that the reflected heat is conveyed through the air by pulſations, like ſound, &c. but this opinion does not ſeem well founded.

There are two modes of communicating heat, which to all appearances are eſſentially different, though perhaps the difference may not be real; the one called *radiation*, is that by which the ſun and all ignited and hot bodies diſperſe their heat in every direction, when ſurrounded by an elaſtic medium or a vacuum; the other, the ſlow and gradual communication of heat, ſuch as is experienced along a bar of iron when one end of it is put into a fire; the heat appears to travel from one molecule to another till it arrives at the extremity, and is then thrown off or radiated into the air.

The laws of the radiation of heat and the ſubſequent reflection of it, have lately been inveſtigated with great ſkill by Mr. Leſlie, and ſome new and unexpected reſults have been obtained. See his "Enquiry on Heat." 1ſt. The quantity of heat which radiates from a body depends in great part on the ſurface of the body; if the body is covered with black paint, paper, &c. it will radiate eight times as much heat as if the ſurface was metallic. 2dly. If the bulb of a thermometer be covered with tinfoil, the impreſſion of radiant heat upon it is only $\frac{1}{2}$ of what it would be upon the glaſs ſurface of the thermometer. 3dly. A metallic mirror reflects 10 times as much heat from an ordinary fire, or from any heated body, as a ſimilar glaſs mirror does. The laſt too reflects the heat from its *anterior* ſurface, and not from the quickſilvered one. This circumſtance exhibits a difference between ſolar and culinary heat. From theſe facts it ſhould ſeem that metals are eminently diſpoſed to *reflect* radiant heat, and of courſe not to abſorb it; whereas black paint, paper, glaſs, &c. are diſpoſed to *abſorb* and not to reflect it; but when elevated in temperature they

they are eminently disposed to *radiate* heat. In fact this power is probably proportional to their capacity for heat. 4thly. Screens of glass, paper, tinfoil, &c. being placed between the radiating body and the reflector, were proved to intercept the radiant heat completely; but being heated themselves by the direct radiant heat, in time the thermometer was affected by their radiation. The heat radiating from hot water, does not then seem capable of being transmitted through glass, like the solar heat. 5thly. Radiant heat suffers no sensible loss in its passage through the air; a greater or less radiant body produces the same effect, provided it subtends the same angle at the reflector, agreeing with light in this respect. 6thly. The intensity of reflected heat diminishes inversely as the distance; that is, the density of heat reflected from a concave mirror in any point of the focus, is inversely as the distance of the hot body from the mirror; whereas in regard to light, the density is known to be uniformly the same, or subject to no change on account of distance. The focus of heat, too, differs from that of light, being nearer to the reflector. The heating effect diminishes rapidly in going out, but slowly in going inward towards the reflector. These are new and unexpected facts, which, if established, will afford some remarkable differences betwixt heat and light. 7thly. The quantity of heat which a strongly radiating surface throws off, is somewhat more than that which is carried off by the atmosphere according to Mr. Leslie; but Mr. Dalton infers it to be somewhat less.

For the law observed in the cooling of bodies, see REFRIGERATION.

2. The slow and gradual communication of heat from particle to particle, is a phenomenon which appears under two very different points of view, as we contemplate it in a fluid or solid body. In a fluid, the particles are no sooner heated than they become specifically lighter, and immediately commence an ascending motion in the fluid (if they are not already on the surface). By these means the circulation or diffusion of the heat is infinitely accelerated. The fact has been finely elucidated by the experiments of count Rumford, in his seventh essay. But in the case of solid bodies, the particles of which are fixed, the heat must be propagated from one to another, *seriatim*. Whether this communication is by radiation, as in the former case, is not very easy to decide; perhaps the slowness of the progress of heat may depend upon the infinite number of successive radiations from particle to particle. Some solids conduct heat much quicker than others. See CONDUCTORS *of heat*.

Free or Sensible HEAT.—This phrase was lately common amongst writers on the subject of heat, and is still used by some; whenever heat is added to or taken from a body, and a proportionate change of temperature is observed in the body, then the heat is said to be *free* or *sensible* to the thermometer.

Latent HEAT.—This phrase was first used by Dr. Black. It was suggested from the discovery, that a large quantity of heat sometimes disappears, or is absorbed by a body, without any increase of temperature. This commonly happens when a body from a solid becomes liquid, or from a liquid becomes aeriform: and sometimes, when two bodies of the same temperature combine, a great degree of cold is produced, but when a due portion of heat is acquired from the surrounding bodies, the temperature is restored. The heat which disappears in these cases is called *latent*. The expression was perfectly proper and unexceptionable in the first instance, as simply denoting a fact, and perhaps was never understood in any other sense by Dr. Black; but his pupils soon began to perceive that latent heat must, in all probability, be chemically combined with the body, and on this account, in a state different from the sensible or common heat which those bodies give or receive upon a change of temperature. This notion might have been right, but succeeding experience has shewn it to be otherwise. The heat so absorbed has been found in most, if not all cases, to be employed in enlarging the capacity of the new-formed body for heat, and is therefore precisely in the same situation as the rest of the heat in the body. The phrases *free* and *sensible* heat, and *latent* heat are now therefore disused by the most distinguished writers, as calculated to suggest incorrect views of the subject.

Animal HEAT.—The excess of temperature which certain animals possess above that of the surrounding medium is called *animal heat*. The cause of this has been an object of eager enquiry amongst physiologists. We owe the principal elucidation of this obscure subject to the modern discoveries in pneumatic chemistry, and in the general principles of heat, and more particularly to the sagacity and acute observations of the late Dr. Crawford, whose experiments on animal heat, and the inflammation of combustible bodies, may be considered as forming an era in physiological and chemical science.

The temperature of the vital parts of the human body is at a medium about 98° of Fahrenheit. It is observed to be much the same in all seasons and climates; but during an inflammatory fever it has been known to be elevated 10 or 12°. Several of the warm-blooded animals possess nearly the same temperature as man. This temperature, as is well known, is far above the common temperature of the atmosphere; it becomes an object of enquiry then, what is the source of heat in animals, which supplies the constant waste occasioned by the cooling power of the atmosphere. The conjectures and opinions on this head have been various, and most of them improbable, as was likely before the properties of heat and elastic fluids were developed. Some have ascribed animal heat to the attrition of the particles of the blood against the coats of the arteries in the course of circulation; others imagine the source of heat to be in the change the aliment undergoes in the process of digestion; others suppose a gradual evolution of phlogiston in the vascular system to take place, and to be accompanied with heat. Dr. Black was of opinion that respiration was the cause of animal heat, which was generated in the lungs and diffused over the rest of the body by means of the circulation. This opinion Dr. Crawford succeeded in establishing, by a masterly train of reasoning and experience, of which we shall now give an abstract, with such modifications as succeeding discoveries have induced. See Crawford on Animal Heat, 2d edit.

The circumstances that warm-blooded animals are furnished with lungs, and that, in breathing, carbonic acid is generated, could not fail to suggest to Dr. Black an analogy betwixt the combustion of charcoal and respiration; but not following up the views which his discoveries on heat had opened, he suffered Drs. Irvine and Crawford to anticipate him in explaining the phenomena of what he called *latent heat*. Irvine held that the appearance or disappearance of heat, or rather temperature, was owing to a change in the capacities of bodies, produced by chemical or other means; whereas the language of Black was calculated to convey the notion of heat existing in bodies in two distinct modes, namely, as *sensible* and *latent*, or *free* and *combined* heat, terms which have been adopted since by many writers to convey such signification. (Which see below.) Crawford pursued the path pointed out by Irvine. He lays down a number of general facts concerning heat, which he supports by appro-

priate

priate obſervations, namely, 1. That heat has a tendency to diffuſe itſelf. 2. That the quantity of heat in a body is limited. 3. That the quantity of heat in an homogeneous body of a given temperature is as its bulk. 4. That the variations in the quantity of abſolute heat in an homogeneous body, while it retains its form, are nearly proportional to its variations of temperature, as meaſured by a mercurial thermometer. 5. That the capacities of bodies for containing heat are nearly permanent, while they retain their form. 6. That when, by expoſure to heat, ſolid bodies become fluid, they abſorb a portion of heat which is neceſſary to their fluidity, and which does not increaſe their temperature; and when, by expoſure to cold, they become ſolid again, they part with the heat which they had before abſorbed,—that when water is converted into vapour, a quantity of heat is abſorbed, which does not increaſe the temperature. And, 7. That unequal quantities of abſolute heat are neceſſary, to produce equal changes of temperature in heterogeneous bodies.

Though ſeveral of theſe facts are ſufficiently evident to be admitted as axioms, yet others are not ſo, and even ſome queſtion ſtill exiſts as to their accuracy; but ſuppoſing that doubtful, the circumſtance will ſcarcely affect the general concluſions reſpecting the origin and diffuſion of animal heat.

Crawford advances the following ſeries of propoſitions: 1. That the quantity of abſolute heat contained in pure air (oxygenous gas) is diminiſhed by the change which it undergoes in the lungs of animals, and the quantity of heat in any kind of air that is fit for reſpiration, is nearly proportional to its power of ſupporting animal life. This propoſition is ſupported by the reſults of a great variety of very ingenious but delicate experiments on the heat imparted by elaſtic fluids. The former part of the propoſition is the only one eſſential to the theory; the latter part is probably incorrect, as neither the nature nor number of elaſtic fluids was well known at that time. His ſecond propoſition is, that the blood which paſſes from the lungs to the heart, by the pulmonary vein, contains more abſolute heat than that which paſſes from the heart to the lungs by the pulmonary artery. To eſtabliſh this, experiments were made on mixtures of given weights of water and arterial blood, and water and venous blood; from which it appeared that more heat was imparted by arterial blood to water than by venous blood, all other circumſtances being the ſame. In the experiments with the blood of a ſheep, the comparative heats of the arterial and venous blood were as 115 to 100; in thoſe of a dog, as 114 to 100. The third propoſition is, that the comparative quantities of heat in bodies ſuppoſed to contain phlogiſton (combuſtible) are increaſed by the changes which they undergo in the proceſſes of calcination and combuſtion. This propoſition, relating more immediately to the theory of combuſtion, than to that of animal heat, needs no animadverſion here. But though he confirms the fact by various experiments, as far as regards the particular bodies operated upon, it does not ſeem probable that the propoſition is univerſally true. The fourth propoſition is, that when an animal is placed in a warm medium, the colour of the venous blood approaches more nearly to that of the arterial, than when it is placed in a cold medium; the quantity of reſpirable air which it phlogiſticates (that is oxygen, which it converts into carbonic acid) in a given time, in the former inſtance, is leſs than that which it phlogiſticates, during an equal ſpace of time, in the latter; and the quantity of heat produced when a given portion of pure air is altered by the reſpiration of an animal is nearly equal to that which is produced when the ſame quantity of air is altered by the burning of wax or charcoal. This extenſive and important propoſition is ſupported by the reſults of 18 experiments. The firſt conſiſts in immerſing a dog into a warm medium (water or air) for a due time, and then drawing a quantity of blood from an artery and a vein; when the venous blood was found nearly as florid a red as the arterial: but when a dog had been confined for a time, in a cold medium, the venous blood was of a much darker hue than in the former caſe. The ſecond, third, fourth, fifth, ſixth, and ſeventh experiments ſhew that a ſmall animal, ſuch as a guinea-pig, requires more oxygen, and produces more carbonic acid, when placed in a cold than in a warm medium. The eighth ſhews the quantity of heat produced by the combuſtion of a given weight of wax, and the ninth the quantity of oxygen required, or which diſappears in the proceſs. The tenth ſhews the quantity of heat produced by a guinea-pig in a given time, and the eleventh the quantity of oxygen ſpent in the ſame time. The twelfth ſhews the heat produced by the combuſtion of a given weight of charcoal, and the thirteenth and fourteenth the quantity of oxygen which diſappears, and is found in the carbonic acid. From this it appears that the weight of the charcoal is to that of the oxygen as 1 to 2 nearly; but more recent and accurate experiments of other authors find the ratio 1 to 2.6 nearly. In the fifteenth experiment, wax was again burnt to determine whether aqueous vapour was produced in quantity, which appeared to be the caſe; and the ſixteenth and ſeventeenth go to prove, that in the combuſtion of charcoal nothing but carbonic acid is produced. The eighteenth experiment ſeems to prove that in the reſpiration of a guinea-pig ſome of the oxygen is ſpent in producing aqueous vapour; but other experiments, ſince made in more favourable circumſtances, do not warrant this concluſion. Collecting and comparing ſome of theſe reſults it appeared that the heat communicated to 31lb. 7oz. of water was as follows:

100 ounce meaſures of pure air altered	by the combuſtion of wax imparts	21°
	by the combuſtion of charcoal imparts	19°.3
	by the reſpiration of a guinea-pig	17 .3

Upon a review of the preceding facts and propoſitions it ſeems warrantable to conclude, 1ſt. That the air inſpired by animals contains more abſolute heat than the air expired. 2dly. That the blood in the lungs receives the difference of heat, but without any material change of temperature, the capacity of the blood for heat being immediately enlarged, juſt ſo much as to receive the additional heat, without any change of temperature. 3dly. That the blood, during the circulation through the body, gradually changes its capacity from a greater to a leſs, giving out heat to the body to ſupply the waſte, till it again arrives at the lungs, where it parts with charcoal, and receives more heat. 4thly. That the expenditure of heat in an animal is proportional to the carbonic acid produced or loſs of oxygen, and is accurately or nearly the ſame as would be given out by the combuſtion of charcoal in a quantity ſufficient to produce the ſame acid. And, 5thly. That the changes in the capacity and other qualities of the blood are greater, when an animal is placed in a cold than in a warm medium. Hence if theſe concluſions be admitted, the ſource of animal heat, and the mode of its diſtribution to the various parts of the body, muſt be conſidered as ſufficiently demonſtrated.

We ſhall here ſubjoin ſome additional obſervations and facts with regard to animal heat.

The heat of animals is very various, both according to the variety of their kinds and the difference of the ſeaſons: accordingly, zoologiſts have divided them into hot and cold, reckoning thoſe to be hot which are near our own tempera-

ture, and all others cold whoſe heat is much below our's, and, conſequently, affects us with the ſenſe of cold; though, by their *vis vitæ*, they are kept ſomewhat warmer than the medium in which they live. To this latter claſs writers have commonly referred the whole inſect tribe; though Dr. Martine obſerves with reſpect to bees, that the heat of a ſwarm raiſed a thermometer buried among them above 97°, indicating a degree of heat ſcarce, if at all, inferior to our own. To this claſs alſo belong muſcles and oyſters, the bronchial fiſhes, ſnails, frogs, land and ſea tortoiſes, toads, vipers, and all the ſerpent kind.

The human kind forms the loweſt gradation in the claſs of hot animals: the heat of the human body, in its natural ſtate, according to Dr. Boerhaave, is ſuch as to raiſe the mercury in the thermometer to 92°, agreeing with Dr. Pitcairn's obſervation of the heat of the human ſkin, or at moſt to 94°. M. Amontons, by ſeveral trials, found the heat communicated to the human body to be 91°, 92°, and 93°. Sir Iſaac Newton makes the external heat of the human body of the ſame temperature with that of a bird hatching eggs, to be 95°.5. Fahrenheit ſtates the heat of the human body and blood at 96°, which Muſchenbroek aſſigns to be the degree of heat communicated to the thermometer when immerged in the blood flowing from an animal. Dr. Martine infers, from a great number of trials, that the mean heat of the human ſkin is about 97° or 98°; being a little higher in ſome ſubjects, and a little lower in others; and the heat of the human urine, by which we may judge of that of the neighbouring viſcera, he ſays, is ſcarcely a degree hotter than the ſkin. Dr. Hales found the heat of his ſkin to be about 97°, and the heat of urine newly made about 103°. Mr. Hunter found, by ſinking the ball of the thermometer under his tongue, and keeping it there for ſome minutes, that the mercury roſe to 97°: in another experiment, he introduced the ball of the thermometer into the urethra about an inch, and when it had remained there a minute, the quickſilver roſe only to 92°; at two inches it roſe to 93°; at four inches to 94°; and when the ball had got as far as the bulb of the urethra, the quickſilver roſe to 97°. The heat of the rectum was 98°½ exactly.

With reſpect to ordinary quadrupeds, ſuch as dogs, cats, ſheep, oxen, ſwine, &c. the heat of their ſkin raiſes the thermometer four or five diviſions higher than that of the human kind, *viz.* to 100°, 101°, 102°, and ſome to 103°, and a little more. The cetaceous fiſhes are as hot as theſe; and the bird kind, as lord Bacon has long ſince obſerved, are warmer by three or four degrees than quadrupeds: for Dr. Martine has found, by lodging the bulb of the thermometer in the groin of ducks, geeſe, hens, &c. that the mercury was raiſed to 103°, 104°, 105°, 106°, and 107°, and in a hen hatching eggs he once found the height to be 108°. Dr. Crawford has collected the following obſervations relating to this ſubject; that thoſe animals which are furniſhed with lungs, and which continually reſpire the freſh air in great quantities, have the power of keeping themſelves at a temperature conſiderably higher than the ſurrounding atmoſphere: but animals that are not furniſhed with reſpiratory organs, are very nearly of the ſame temperature with the medium in which they live: the former, according to his theory, which is explained in the courſe of this article, continually abſorbing heat from the air, for which purpoſe they are provided with a pulmonary ſyſtem and double circulation. Farther, among the hot animals, thoſe are the warmeſt which have the largeſt reſpiratory organs, and which, conſequently, breathe the greateſt quantity of air in proportion to their bulk: thus, the reſpiratory organs of birds, compared with their ſize, are more extenſive than thoſe of any other animal; and birds are known to have the greateſt degree of animal heat. This fact is likewiſe explained by the ſame theory, and affords a confirmation of it; for, if animal heat depends upon a change which the air undergoes in the lungs, it is evident that, all other circumſtances being equal, the greater the quantity of air which is changed in a given time, the greater muſt be the heat produced. Moreover, in the ſame animal, the degree of heat is in ſome meaſure proportionable to the quantity of air inſpired in a given time: thus, we find that animal heat is increaſed by exerciſe, and by whatever accelerates reſpiration.

But it is obſerved, that the heat of animals varies in different individuals, and likewiſe in the ſame animals at different times; for, though in a healthful ſtate the variations are not great, yet, by accidents and diſeaſes, they may be much altered, and brought conſiderably above and below the natural ſtandard. Dr. Hales ſuppoſes the heat of the human blood in high fevers to be about 136°½; and Dr. Boerhaave relates certain experiments of Fahrenheit and others, from which it appears that animals were very ſoon deſtroyed in a heat of 146°; a ſparrow having died in leſs than ſeven minutes, a cat in about fifteen, and a dog in twenty-eight: and he concludes in general, that the ſerum of the blood may be coagulated by a degree of heat not much above 100°; whence Dr. Hales and Dr. Arbuthnot have been led to affirm, that the natural heat of the blood of a human creature approaches very near the degree of coagulation. But Dr. Martine obſerves, that he has found the blood to be heated five or ſix degrees above 100°, without any ſuch pernicious effects; and that the ſerum of blood and the white of an egg have continued thin and liquid, till the thermometer had indicated a degree of heat equal to 156°, which he ſuppoſes to extend beyond any thing that can ever be experienced by a living animal. The late ingenious Mr. Hewſon infers, from ſeveral experiments, that the lymph of the human blood coagulates at a degree of heat between 114° and 120°½; and that the ſerum does not coagulate without 160° of heat: there is, therefore, no ground for the apprehenſion of Boerhaave and others, that the blood ſhould be coagulated by the animal heat, even whilſt it is circulating in the blood-veſſels; ſince the animal heat is naturally only 98° or 100°, and in the moſt ardent fever it is not raiſed above 112°. Phil. Tranſ. vol. lx. art. 33.

From ſome experiments made by Dr. Dobſon in a heated room it appears, that the white of an egg, incloſed in its own film, remained fluid in a heat of 224°, but coagulated in the ſame heat when contained in a tin veſſel or its own ſhell: he offers ſeveral conjectures for the explication of this phenomenon; the moſt probable of which ſeems to be, that tin is a more powerful conductor of fire from air, and robs this medium of its heat more readily than the film can do.

Philoſophers, miſled by the opinion of Boerhaave and the experiments above recited, had very generally imagined, that animals were incapable of enduring, without danger, any very conſiderable degree of heat: however, governor Ellis had obſerved, as long ago as the year 1758, that a man can live in air of a greater heat than that of his own body, and that the body in this ſituation continues its own cold. Phil. Tranſ. vol. l. p. 755.

Nevertheleſs, it was ſcarce conceivable, by reaſoning *à priori*, and in oppoſition to a ſuppoſed fact, that the human body could be ſafely expoſed to a heat only of the degree which proved fatal to the animals in the experiments related by Boerhaave. Accident, we may ſay, firſt led to the diſcovery of the fallacy of the general opinion on this ſubject. Meſſrs. Du Hamel and Tillet being employed in the years 1760 and 1761, in deſtroying an inſect which conſumed the

grain

grain of the province of Angoumois, contrived, for this purpose, to expose the affected corn, with the insects included in it, in an oven, the heat of which was sufficient to kill them without injuring the grain. With a view of ascertaining the heat of this oven, they conveyed into it a thermometer, and being desirous of knowing the precise heat of the mercury whilst the thermometer remained in the oven, a girl, one of the attendants on the oven, entered it, and marked the thermometer with a pencil, after staying two or three minutes, and the heat was found to be near 260° of Fahrenheit's scale; she afterwards remained there ten minutes longer, the mercury in the thermometer standing at 288°, or 76° above that of boiling water; and when she came out of the oven, her complexion was considerably heightened, but her respiration was by no means quick and laborious. These experiments were afterwards repeated, when another girl remained in the oven without much inconvenience, and under the same degree of heat, as long as the former, and even breathed in air heated to about 325° for the space of five minutes. These girls, says M. Tillet, were protected from the external action of the heat by their cloaths, which are bad conductors of heat, and enabled to breathe the air, thus violently heated, for a long time, without great inconvenience: to which we may add, says an ingenious anonymous remarker on this experiment, that the bulk of their bodies might also contribute to their security; and as in common respiration, the blood in its passage through the lungs is cooled by being brought into contact with the external inspired air: in the present case, on the contrary, the vesicles and vessels of the lungs, receiving at each inspiration an air heated to 300°, must have been continually cooled and refreshed, as well as the subcutaneous vessels, by the successive arrival of the whole mass of blood contained in the interior parts of the body, whose heat might be supposed, at the beginning of the experiment, not to exceed 100°. Hist. Acad. Scienc. 1764, mem. ii.

These extraordinary facts might possibly lead philosophers into a new train of reasoning and experiment on the subject of heat: accordingly, we find that Dr. Cullen has long ago suggested many arguments to shew, that living animals have a power of generating heat, independently of any common chemical or mechanical means either of friction or fermentation, and also of generating cold or destroying heat, when the heat of the atmosphere exceeded the proper temperature of their bodies. In order to examine and ascertain this theory, Dr. George Fordyce prepared a suit of three rooms heated by flues in the floor; in one of which the air was in a dry state, and in another loaded with moisture, by pouring boiling water on the floor. In the first room the highest thermometer stood at 120°, and the lowest at 110°; in the second the heat was from 90° to 85°; and the third room felt moderately warm, whilst the external air was below the freezing point. Dr. Fordyce, having undressed himself to his shirt in the third room, entered the second room, and staid five minutes in a heat of 90°; he then entered the first room, and having remained in the part heated to 110° for ten minutes, the water running down in streams over his whole body, he removed to the part of the room heated to 120°, and after staying there twenty minutes, he found that the thermometer, placed under his tongue and held in his hand, stood just at 100°, and that his urine was of the same temperature; his pulse had gradually risen till it made 145 pulsations in a minute; the external circulation was greatly increased, but his respiration little affected. The moisture of his skin, he apprehended, was chiefly owing to the condensation of the vapour in the room upon his body. In the second experiment, the highest thermometer in the first room varied from 132° to 130°, and the lowest stood at 119°. Having undressed in an adjoining chamber, he went first into the heat of 119°, and in half a minute the water flowed down over his whole body in streams; having remained here fifteen minutes, he went into the heat of 130°; at this time the heat of his body was 100°, and his pulse beat 126 times in a minute; in this situation a Florence flask, filled with water, heated to 100°, and wiped dry, became wet, and streams of water continued to run down its sides, till the heat of the water within had risen to 122°. In this heat he remained fifteen minutes, and just before he left the room his pulse made 139 beats in a minute, but the heat under his tongue, in his hand, and of his urine, did not exceed 100°.

Dr. Fordyce observes, on this experiment, that there was no evaporation, but constantly a condensation of vapours on his body, and no cold was generated but by the animal powers. Having continued much longer in a much greater dry heat without being so much affected, he takes occasion to infer, from this circumstance, that dry air does not communicate its heat like air saturated with moisture; and that the evaporation from the body, which takes place when the air is dry, assists its living powers in producing cold.

In another experiment, Dr. Fordyce, accompanied with four other gentlemen, went into the heated chamber where the air was dry, without taking off their clothes. When they first entered the room, the quicksilver stood above 150°, and they continued in it more than twenty minutes, in which time the heat had risen about 12°. In another period of this experiment, the quicksilver stood at 198°, and they continued in this heat about ten minutes; but finding that the thermometer sunk very fast when they went together, they agreed to go in separately. Dr. Solander stood in the room heated to 210° for three minutes, during which time the quicksilver sunk to 196°; and Mr. Banks (sir Joseph) remained seven minutes in the heat of 211°, in which time the quicksilver had sunk to 198°. The heat of their bodies in these several experiments rose very little above its usual state; and many striking effects proceeded from their power of preserving their natural temperature. Whenever they breathed on the thermometer, the mercury sunk several degrees; every expiration afforded a pleasant cooling impression to the nostrils, and their cold breath cooled their fingers. Dr. Blagden, on touching his side, found that it felt like a corpse, though the actual heat of his body was 98°. When the heat of the air began to approach the highest degree which the apparatus made use of was capable of producing, their bodies in the room prevented it from rising any higher; and when it had been previously raised above that point, immediately sunk it. These, and other circumstances attending the experiments, clearly prove, that the body has a power of destroying heat; but, in estimating the heat which we are capable of resisting, it is necessary to consider not only what degree of heat would be communicated to our bodies, if they possessed no resisting power, by the heated body, before the equilibrium of heat was affected, but also what time that heat would take in passing from the heated body into our bodies. On this principle, we bear very different degrees of heat in different mediums; and it appears, by other experiments, that the same person, who felt no inconvenience from air heated to 211°, could not bear quicksilver at 120°, and could just bear rectified spirit of wine at 130°, *i. e.* quicksilver heated to 120° furnished, in a given time, more heat for the living powers to destroy than spirits heated to 130°, or air to 211°. Accordingly, when they were in the heated rooms, their watch-chains and other pieces of metal felt so hot, that they could scarcely touch them:

whilſt the air, from which the metal derived all its heat, was only unpleaſant. From theſe experiments, it is concluded that no attrition, fermentation, or whatever elſe the mechanical and chemical phyſicians have deviſed, can explain a power capable of producing or deſtroying heat, juſt as the circumſtances of the ſituation require; this power muſt be referred to the principle of life itſelf; and yet this is only giving a name to a ſtill unknown cauſe. This power, however it acts, ſeems to attend life very univerſally; Mr. Hunter found a carp preſerve a coat of fluid water round him long after all the other water in the veſſel had been congealed by a freezing mixture; and he has alſo ſhewn, that vegetables poſſeſs ſome degree of this property of generating heat. The ſudden melting of ſnow on graſs, whilſt that on the gravel walk continues unthawed, and many other ſimilar phenomena, can be adequately explained only on this principle.

In ſubſequent experiments, the heat of the room was raiſed to 240, and ſometimes to 260°; theſe exceſſive heats were borne for a conſiderable time with little inconvenience by the gentlemen, who expoſed themſelves to them, both naked and with their clothes on; nor was the heat of Dr. Blagden's body at all increaſed, though the velocity of his pulſe was, in one inſtance, more than doubled. A blaſt of the heated air from a pair of bellows was ſcarcely to be endured for the following obvious reaſon: when the ſame air remained for any time in contact with the body, part of its heat was deſtroyed, and, conſequently, the body was ſurrounded with a colder medium than the air of the room; whereas, when freſh portions of the air were applied to the body in ſuch a quick ſucceſſion, that no part of it could remain in contact a ſufficient time to be cooled, the heat muſt be ſenſibly greater. On this occaſion the gentlemen evinced the fallacy of the experiment related by Boerhaave, and which has been already mentioned; they ſhut up a bitch in the heated room, when the thermometer had riſen to 210; in this ſituation ſhe was ſuffered to remain without being immoderately affected, for 32′, and when ſhe was releaſed, and brought again into the cold air, ſhe appeared not to have received the leaſt injury. In the ſame heated air, which they breathed, eggs were roaſted quite hard in 20′, and beef-ſtakes were dreſſed in 33′; and by blowing the air upon ſome of them, in 13′.

The effect of evaporation, in preventing certain bodies, and particularly fluids, from receiving a degree of heat equal to that of the air, is ſhewn by ſome of theſe experiments to be very conſiderable. In the great heat juſt mentioned, pure water, expoſed in an earthen veſſel during an hour and a half, acquired only a heat of 140°, and afterwards continued ſtationary above an hour, at a degree much below the boiling point; but when its power of evaporating was checked, by dropping a ſmall quantity of oil on its ſurface, it boiled very briſkly. A ſaturated ſolution of ſea-ſalt acquired a heat of 230°, and was, conſequently, brought into a briſk ebullition, on covering its ſurface with a layer of oil.

Dr. Dobſon has alſo publiſhed an account of ſimilar experiments made by him in the ſweating-room of the hoſpital at Liverpool; the reſults of which are conformable to thoſe that have been already recited. It appears from theſe, as well as from the former experiments, that the pulſe is conſiderably accelerated by heated air, whilſt the animal heat varies little from its natural ſtandard; a fact which, as Dr. Dobſon obſerves, contradicts the opinion that has been generally received with regard to the cauſe of animal heat, viz. that it is produced by the attrition of the globules of the circulating fluids againſt the ſides of the containing veſſels; whereas it is ſeen, that the circulation may be amazingly quickened, whilſt there is little increaſe of the animal heat.

We may conclude in general, from the experiments and obſervations already recited, that man is ſo framed as to poſſeſs a power of keeping nearly the ſame tenor of heat in all the variations of the temperature of the air in ſummer and winter, in hot and cold climates; and, conſequently, changes his ſituation on the ſurface of the globe with much leſs inconvenience or injury than he could otherwiſe have done. The ſame power likewiſe happily adapts different animals to their reſpective deſtinations; the lizard and the cameleon remain cool under the equator, whilſt the whale and porpoiſe retain a degree of heat above that of the human body, though ſurrounded with the waters of the coldeſt northern ſeas, and amidſt mountains of ice, in the neighbourhood of the Pole.

Dr. Crawford obſerves, with regard to the power above illuſtrated, which animals poſſeſs, of producing cold, that, by the heat of the ſurrounding medium, the evaporation from the lungs is increaſed: and that if this increaſe to ſuch a degree as to carry off the whole of the heat which is detached from the air, the arterial blood, when it returns by the pulmonary vein, will have its ſenſible heat greatly diminiſhed, and will, conſequently, abſorb heat, from the veſſels which are in contact with it, and from the parts adjacent. And thus the ſame proceſs, which in one caſe ſupplies the animal with heat, according to Dr. Crawford's theory, will now become the inſtrument of producing cold; and the quantity of cold produced will be in proportion to the velocity of the blood through the lungs, and the fulneſs and frequency of the reſpiration. Thus, in winter ſeaſons, and cold climates, the veſſels on the ſurface of the body are conſtricted, the blood is determined to the lungs, and the pulſe and reſpiration are rendered full and frequent; ſo that the quantity of heat abſorbed from the air is proportionably increaſed. But in ſummer, the blood is determined to the ſurface, the velocity of the circulation through the lungs is diminiſhed, and the quantity of heat abſorbed is diminiſhed: beſides, if the quantity of heat abſorbed by the vapour exhaled in reſpiration be ſo great, as that the remaining portion of the heat depoſited by the air is not ſufficient to ſupport the temperature of the arterial blood, ſome degree of cold will be produced in conſequence of the change which the blood undergoes in the lungs. Martine's Eſſay, Eſſ. vi. Phil. Tranſ. vol. lxv. part i. art. 12. Id. ibid. part ii. art. 43. art. 45. art. 47. Id. vol. lxviii. part i. art. 2. Crawford on Heat, &c. p. 31. 80, &c.

Heat, in *Geography*. The diverſity of the heat of climes and ſeaſons ariſes from the different angles under which the ſun's rays ſtrike upon the earth's ſurface.

It is ſhewn in mechanics, that a moving body ſtriking perpendicularly on another, acts on it with all its force; and that a body ſtriking obliquely, acts with the leſs force, the more it deviates from the perpendicular. Now fire, moving in right lines, muſt obſerve the ſame mechanical law as other bodies; and conſequently its action muſt be meaſured by the ſine of the angle of incidence: and hence fire, ſtriking on any obſtacle in a direction parallel thereto, has no ſenſible effect, becauſe the ratio is almoſt infinite, *i. e.* it is nothing. Accordingly, the ſun, radiating on the earth in the morning, ſcarcely produces any warmth at all.

Hence Dr. Halley gives a mathematical computation of the effect of the ſun under different ſeaſons and climates; proceeding on this principle, that the ſimple action of the ſun, as all other impulſes or ſtrokes, is more or leſs forcible, according to the ſines of the angles of incidence, or to the perpendiculars let fall on the plane; whence, the vertical

ray

ray (which is of the greateſt heat) being put for radius, the force of the ſun on the horizontal ſurface of the earth will be to that, as the ſines of the ſun's altitude at any other time.

Hence it follows, that the time of the continuance of the ſun's ſhining being taken for a baſis, and the ſines of the ſun's altitude erected on it as perpendiculars, and a curve drawn through the extremities of thoſe perpendiculars, the area comprehended will be proportionate to the collection of the heat of all the ſun's beams in that ſpace of time.

Hence it will follow likewiſe, that under the pole the collection of all the heat of a tropical day is proportionate to a rectangle of the ſine of 23 degrees and a half into 24 hours, or the circumference of a circle; that is, the ſine of 23 degrees and a half being nearly $\frac{4}{10}$ of radius, as $\frac{8}{10}$ into 12 hours. Or, the polar heat is equal to that of the ſun continuing 12 hours above the horizon at 53 degrees height; than which the ſun is not five hours more elevated under the equinoctial.

But whereas the nature of heat is to remain in the ſubject, after the luminary that occaſioned its being heated is removed, and particularly in the air, under the equinoctial the twelve hours abſence of the ſun does but little diminiſh the motion impreſſed by the paſt action of his ray wherein heat conſiſts, before he riſes again; but under the poſe, the long abſence of the ſun for ſix months, wherein the extremity of cold does obtain, hath ſo chilled the air, that it is, as it were, frozen, and cannot, before the ſun has got far towards it, be any ways ſenſible of his preſence, his beams being obſtructed by thick clouds, and perpetual fogs and miſts.

That heat and cold very much depend on the clearneſs or opacity of the ſky, is atteſted by facts; for the winter cold in South America is very ſharp, becauſe the atmoſphere is loaded with clouds and icy particles, which intercept the ſolar rays. At Lima, in lat. 12° ſouth, where the ſky is never free from vapours, the heat is moderate, but at the diſtance of a few miles the ſky is more ſerene, and there the heat is greater; and at Carthagena, in lat. 11° north, the heat is, principally on this account, intolerable. Add, that the different degrees of heat and cold, in different places, depend, in a very great meaſure, upon the accidents of ſituation, with regard to mountains or vallies, rivers, ſeas, and woods, and the nature and colour of the ſoil, &c. The firſt, eſpecially when they are lofty and covered with ſnow, greatly help to chill the air by the winds which come over them, and which blow in eddies through the levels beyond. Accordingly, the higheſt mountains, even under the equator, are, during the whole year, covered with ſnow. Thus, M. Bouguer found the cold of Pinchinea, one of the Cordilleras, elevated 5760 feet above Quito, immediately under the line, to extend from ſeven to nine degrees under the freezing point every morning before ſun-riſe; and hence at a certain height, which varies in almoſt every latitude, it conſtantly freezes at night in every ſeaſon, though in the warm climates it thaws to ſome degree the next day. This height he calls the "lower term of congelation," which he places between the tropics at the height of 15,577 feet; but in lat. 28°, he thinks that it ſhould commence, in ſummer time, at the height of 13,440 feet from the level of the ſea. See CONGELATION.

Mountains ſometimes, turning a concave ſide towards the ſun, have the effect of a burning mirror on the ſubject plain; and the like effect is ſometimes had from the concave or convex parts of clouds, either by refraction or reflection. And ſome have even taken theſe to be ſufficient to kindle the exhalations lodged in the air.

As to ſoils; a ſtony, ſandy, or chalky earth, it is known, reflects moſt of the rays into the air again, and retains but few; by which means a conſiderable acceſſion of heat is derived to the air; as, on the contrary, black looſe ſoils abſorb moſt of the rays, and return few into the air, ſo that the ground is much the hotter.

This the peaſants, who inhabit the moraſs de Veenen, where turf is dug, are very ſenſible of: walking there but a little while, the feet grow extremely hot, but the face not at all; on the contrary, in a ſandy place, the feet are ſcarce warm, when the face is ſcorched by the great reflection.

It is certain, that heat communicated by the ſun to bodies on the earth, depends much upon other circumſtances beſides the direct force of its rays. Theſe muſt be modified by our atmoſphere, and variouſly reflected and combined by the action of the ſurface of the earth itſelf, to produce any remarkable effects of heat; ſo that if it were not for theſe additional circumſtances, it is much to be queſtioned whether the naked heat of the ſun would be very ſenſible. To this purpoſe, it is obſerved by Ulloa, in his Voyage to Peru, that on the weſtern ſhore of that kingdom, from Santa Maria de la Parilla to Lima, it is winter on the mountains from January or February to June, whilſt it is ſummer in the vallies; but from June to November or December, it is winter in the vallies, and ſummer in the mountains. See on this ſubject the article *Temperature of the* ATMOSPHERE.

The following table gives the heat to every tenth degree of latitude to the equinoctial and tropical ſun, by which an eſtimate may be made of the intermediate degrees:

Lat.	Sun in ♈ ♎	Sun in ♋	Sun in ♑
0	20000	18341	18341
10	19696	20290	15834
20	18794	21737	13166
30	17321	22651	10124
40	15321	23048	6944
50	12855	22991	3798
60	10000	22773	1075
70	6840	23543	000
80	3473	24673	000
90	0000	25055	000

For an account of the general principles and problem, by which this table is calculated, ſee Phil. Tranſ. abr. vol. ii. p. 167, &c.

From this table are deducible the following corollaries:

1. That the equinoctial heat, when the ſun becomes vertical, is as twice the ſquare of the radius; which may be propoſed as a ſtandard to be compared with, in all other caſes.

2. That under the equinoctial, the heat is as the ſine of the ſun's declination.

3. That in the frigid zones, when the ſun ſets not, the heat is as the circumference of a circle into the ſine of the altitude at 6. And conſequently, that in the ſame latitude theſe aggregates of warmth are as the ſines of the ſun's declination; and, at the ſame declination of the ſun, they are as the ſines of the latitudes, and generally they are as the ſines of the latitudes into the ſines of declination.

4. That the equinoctial day's heat is every where as the coſine of the latitude.

5. In all places where the ſun ſets, the difference between the ſummer and winter heats, when the declinations are contrary, is equal to a circle into the ſine of the altitude at 6, in the ſummer parallel; and, conſequently, thoſe differences

ences are as the fines of the altitude into, or multiplied by, the fines of declination.

6. From the foregoing table it appears, that the tropical fun, under the equinoctial, has of all others the leaft force; under the pole it is greater than any day's heat whatever, being to that of the equinoctial as 5 to 4.

From the table, and thefe corollaries, a general idea may be conceived of the fum of all the actions of the fun in the whole year; and thus that part of heat which arifeth fimply from the prefence of the fun may be brought to a geometrical certainty. The heat of the fun, for any fmall portion of time, is always as a rectangle, contained under the fine of the angle of incidence of the ray producing heat at that time.

Many objections have been urged againft the preceding theory of Dr. Halley: fome have urged, that the effect of the fun's heat is not in the fimple ratio of the fines of the angles of incidence, but in the duplicate ratio of thefe fines; alleging, that this is the law of the impulfe of fluids. (See FORCE.) Dr. Halley himfelf was well appriſed, that many other circumftances, befides the direct force of the fun's rays, contributed to augment or diminifh the effect of this and the heat refulting from it in different climates; and, therefore, no calculation, formed on the preceding theory, can be fuppofed to correfpond exactly with obfervation and experiment. It has alfo been objected, that, according to the preceding theory, the greateft heat in the fame place fhould be at the fummer folftice, and the moft extreme cold at the winter folftice; which is contrary to experience. (See *Temperature of the* ATMOSPHERE.) To this objection it may be partly replied, that heat is not produced in bodies by the fun inftantaneoufly, nor do the effects of his heat ceafe immediately when his rays are withdrawn; and, therefore, thofe parts which are once heated, retain the heat for fome time, which, with the additional heat daily imparted, makes it continue to increafe, though the fun declines towards the fouth: and this is the reafon why July is hotter than June, although the fun has withdrawn from the fummer tropic; as we find it is generally hotter at three in the afternoon, when the fun has declined towards the weft, that at noon, when he is on the meridian. As long as the heating particles, which are conftantly received, are more numerous than thofe which fly away or lofe their force, the heat of bodies muft continually increafe. After the fun has left the tropic, the number of particles, which heat our atmofphere and earth, conftantly increafes, becaufe we receive more in the day than we lofe at night, and therefore our heat muft alfo increafe. *E. gr.* Let us fuppofe that there are 100 heating particles received in the day, whilft the fun is above our horizon; and that, as the night is much fhorter, 50 of them fly off; the other 50 ſtill remaining to excite heat: the next day, the fun acting with almoft the fame force, will impart 100 particles more, of which one half will efcape in the night; fo that, on the beginning of the third day, the number of particles exciting heat will be increafed by 100: and thus while there are more particles that excite heat received in the day-time than thofe that fly off in the night, the heat muft increafe. But as the days decreafe, and the action of the fun becomes weaker, more particles will fly off in the night time than thofe we receive in the day, by which means the earth and air will gradually cool. Farther, thofe places which are well cooled require time to be heated again; and, therefore, we find January for the moft part colder than December, although the fun has withdrawn from the winter tropic, and begins to emit his rays more perpendicularly upon us.

It is well known that the fun is farther from the earth in fummer than in winter, becaufe his apparent motion is flower, and his apparent diameter lefs in June than in December: but, as the eccentricity of the earth's orbit bears no greater proportion to the earth's mean diftance from the fun than 17 does to 1000, this fmall difference of diftance cannot occafion any great difference of heat or cold. But the principal caufe of the difference between the heat of fummer and that of winter is, that in fummer the rays fall more perpendicularly, and pafs through a lefs denfe part of the atmofphere; and therefore, with greater force, and in greater number on the fame place: and, befides, by their long continuance, a much greater degree of heat is imparted by day than can fly off by night. The effect of rays, according to their various degrees of obliquity, has been already ſtated; and it will appear (by *Plate* XVI. *Aſtronomy*, *fig.* 138.) that a greater number of rays fall on the fame place, when they come perpendicularly, than when they come obliquely upon it: for let A B repreſent a certain number of the fun's rays falling on C D, *e. gr.* London, on the 21ſt of June; but on the 22d of December, the line C D, or London, has the oblique poſition C *d* to the fame rays; and, thereforce, fcarcely a third part of them falls upon it, or only thofe between A and *e*; all the reſt being expended on the fpace *d* P, which is more than double the length of C D or C *d*.

Dr. Long, eſtimating the degree of heat by the fines of the angles of incidence of the fun's rays, computes the fun's heat at noon at the fummer folſtice to be in proportion to his heat at noon at the winter folſtice, in Cambridge, nearly as 100 to 28; for, the meridian height of the ſun, at the fummer folſtice, being there 61° 19′, and his height at the winter folſtice 14° 21′, the fines of theſe angles are 8772858 and 2478445 reſpectively.

Monſ. de Mairan, allowing for the principal cauſes of the ſummer heat, ſtates the proportion of ſummer heat to that of winter as 66 to 1. The method he purſues in forming his calculation is briefly as follows: he aſſigns the proportion of the ſines of the meridional heights of the ſun at the ſummer and winter ſolſtices to be as 3 to 1, and the ratio of the heat, which he ſuppoſes to be as the ſquares of the ſines, that of 9 to 1; and as the rays of the ſun proceed through a leſs ſpace of air in ſummer than in winter; he ſtates the increaſe of ſummer heat on this account to be in the proportion of 2 to 1, and that ariſing from the greater length of days as 4 to 1; and, therefore, the heat of ſummer is to that of winter as 72 to 1. But there are ſome other circumſtances, particularly the greater diſtance of the ſun in ſummer than in winter, which induce him to reduce this proportion of 72 to 1 to that of 66 to 1.

However, M. Amontons has, from obſervation, made the proportion of ſummer heat to that of winter as 60 to 51½; and M de Mairan, in order to reduce his calculation to fact, ſuppoſes that in the earth and air there is a conſtant fund of heat, equal to 393 degrees, to which 66 degrees muſt be added in ſummer, and 1 in winter, and thus he adjuſts his own proportion of 66 to 1 to that of M. Amontons, or 60 to 51½. Keill's Aſt. Lect. viii. Ferguſon's Aſt. chap. x. Long's Aſt. § 777. Mem. Acad. Science. 1719. But all calculations of this kind muſt be in a conſiderable degree fallacious, on account of collateral circumſtances, that contribute to increaſe or diminiſh the effect of the ſun's rays, as we have already ſhewn in this article, and more fully under *Temperature of the* ATMOSPHERE.

With regard to the temperature or heat of our atmoſphere we may obſerve that the mercury ſeldom falls under 16 in Fahrenheit's thermometer; but we are apt to reckon it very cold at 24°, and it continues coldiſh to 40 and a little above.

However, ſuch colds have been often known as to bring it down to 0°, the beginning of the ſcale, or nearly the cold produced by a mixture of ſnow and ſalt. This, as Dr. Boerhaave ſeems to think, is the greateſt degree of cold which nature has ever been obſerved to produce on our earth; but the fallacy of this opinion has been evinced by a variety of obſervations in climates that may be reckoned ordinarily temperate. In Pennſylvania, in lat 40°, the cold brought the mercury to 5° in 1732; at Paris, in 1709 and 1710, the mercury ſunk to 8°; at Leyden, in 1729, to 5°, and at Utrecht to 4°; at London, in 1709 and 1710, the cold ſunk the ſpirits almoſt down to the artificial cold of an ice and ſalt mixture; and, in 1709, the mercury ſunk to 0° at Copenhagen, lat. 55° 43'. At Upſal, in 1732, the cold was ſo great as to be ſufficient to make the mercury fall one degree below 0°; and at Peterſburgh, lat. 59° 56', much the ſame with that of Upſal, the cold was ſevere enough to depreſs the mercury to 28 below 0°.

We learn from Dr. King's Obſervations on the Climate of Ruſſia, that the cold at St. Peterſburgh, during the months of December, January, and February, is uſually from 8 to 15 or 20 degrees below 0°; and that commonly in the courſe of the winter, it is for a week or ten days ſome degrees lower. In this ſeaſon, the water iſſuing from the eyes hangs in little icicles on the eye-laſhes, and icicles appear ſuſpended to the beards of the peaſants in form of ſolid lumps of ice. But in ſtill more northern latitudes the cold is much more extreme. Maupertuis, who wintered at the north polar circle in 1736-7, found the degree of cold at Torneo, lat. 65° 51', ſufficient to have made the mercury ſink to 33 diviſions below 0°. By Mr. Hutchins's obſervations at Albany Fort, lat. 52° 24', the thermometer was at eight o'clock in the morning of the 19th of January, 1775, at 37° below 0°. And yet this degree of cold is inconſiderable, compared with that which may be produced by art. (See FREEZING.) The mean temperature of our atmoſphere is about 52°, which is, as it were, the medium of all the ſeaſons, coinciding nearly with the middle vernal and autumnal heat, as obſerved in England by ſir Iſaac Newton and Dr. Hales, and by Mr. Crucqius in Holland. The French make it ſomewhat higher, reckoning it equal to the heat of the cave of their royal obſervatory, or 53°. In cold countries the air will be found agreeable enough to the inhabitants while it is betwixt 40° and 50°. In our climate we are beſt pleaſed with the heat of the air from about 50° to 60°; while in the hot countries, the air is generally a little above or below 70°. With us the air is not reckoned warm till it arrives at about 64°, and it is very warm and ſultry at 80°: and Dr. Boerhaave thought, that in its natural ſtate it ſcarcely ever exceeded 80° or 90°, apprehending that ſuch hot air would ſoon be deſtructive of the life of animals; but in theſe temperate climates it has been found much hotter; and at Utrecht, Paris, Padua, &c. the mercury would have riſen in our thermometer to above 90°. In Pennſylvania, the ſummer heat in 1732 was once 96 or 97; and at Aſtracan, in July 1746, the heat was ſo great as to raiſe the mercury in M. de Liſle's thermometer in the ſhade to 89°, which correſponds to 103½ of Fahrenheit's; and during the whole month of July, and for ſeveral days in Auguſt, it was higher than 96°, which in Fahrenheit's denotes the natural heat of the blood. Mem. de l'Acad. de Berlin, 1746.

The preceding obſervations are applicable to the ſtate of the air, influenced by the ſun, but ſhaded from its immediate burning operation; for, in the open air, expoſed to its direct beams ſhining with great advantage, the heat is found much higher. Many have had occaſion to obſerve how much metals are heated in the ſun. Dr. Martine found dry earth heated to above 120°; and Dr. Hales found a very hot ſun-ſhine heat in 1727 to be about 140°; but Dr. Muſchenbroek once obſerved it ſo high as 150°; and if we reckon from the freezing point at 32°, theſe ſtrong ſun-ſhine heats were much greater than one-third, or even the half of the heat of boiling water. At Montpelier the ſun was ſo very hot, on one day in the year 1705, as to raiſe the quickſilver in M. Amontons' thermometer to the mark of boiling water itſelf, which is our 212°. But the moſt common noontide heat of the ſun in our climate has been found to raiſe the mercury in the thermometer to about 60 or 70 diviſions above the freezing point at 32°; and the afternoon heat in the ſhade above the half of that; and therefore the ordinary ſummer ſun heat with us does nearly coincide with the heat of our body, and boiling water is between two and three times hotter than our common ſhaded warm air at Midſummer.

Sir Iſaac Newton informs us, that he found the heat of boiling water only about three times greater than the heat communicated to dry earth by the ſummer ſun, or about 92°, with which the obſervations of Muſchenbroek agree; and in Italy, Borelli and Malpighi found this heat at Midſummer equal to the heat of the viſcera of hot animals, or about 102°. In another place (*viz.* Princip. lib. iii. prop. 8. cor. 4) ſir Iſaac Newton eſtimates the heat of boiling water to be ſeven times greater than the heat of the ſummer ſun, which, in this reckoning, ſhould be only at $(32 + \frac{180}{7} =)$ 58: by which, as Dr. Martine remarks, he muſt have meant ſolely the number of degrees above freezing water; and by ſummer ſun, the ordinary ſhaded air in ſummer, or the ſummer heat of the air. (Martine's Eſſ. Med. and Phil. 1740. Eſſ. vi.) It appears, from a regiſter of the thermometer kept at London, by Dr. Heberden, for nine years, *viz.* from the end of 1763 to the end of 1772, that the mean heat at eight in the morning was 47° 4'; and by another regiſter kept at Hawkhill, near Edinburgh, that the mean heat in that place, during the ſame period of time, was 46°. By regiſters kept in London and at Hawkhill, for the years 1772, 1773, 1774, it appears, that the mean heat of theſe three years in London, at eight in the morning, was 48°.5, and at two in the afternoon, 56°, and the mean heat of three years, both morning and afternoon, 52°.2; and the mean heat at Hawkhill for the ſame time, at eight in the morning, was 45°.4, and at two in the afternoon, 50°.1, and the mean heat of morning and afternoon, for the whole time, 47°.7. The mean heat of ſpring near Edinburgh ſeems to be 47°, and at London 51°. Phil. Tranſ. vol. lxv part ii. art. 44.

From the Meteorological Journals of the Royal Society publiſhed in the Philoſophical Tranſactions, it appears, that the mean heights of the thermometer, kept without and within the houſe, are as below:

	Therm. without.	Therm. within.
For 1775 - -	51°.5	52.7
1776 - -	51.1	52.9
1777 - -	51.0	53.0
1778 - -	52.0	53.1

And, therefore, according to theſe obſervations, the mean heat of four years, eſtimated by the external thermometer, is 51°.4. The leaſt height during the period was on the 31ſt January, 1776, at eight in the morning, when it was 13°.5; and the greateſt, which was on the 13th and 14th of July, 1778, at two in the afternoon, was 86°.

HEAT, *Methods of eſtimating its effects on ſolids and fluids.* See PYROMETER and THERMOMETER.

HEAT, in *Agriculture* and *Vegetation*, the fluid matter which pervades different plants and ſubſtances, and promotes their increaſe

increaſe and growth. It has been lately ſuggeſted by an intelligent writer, that ſenſible heat, when applied in a moderate degree, promotes vegetation in a variety of different ways; it excites the activity of plants; it increaſes the diſpoſition of ſome of their conſtituent parts, for new attraction and combination, to obtain ſuch ſubſtances as may be requiſite and proper for their growth; it likewiſe cauſes them to reject ſuch matters as would be hurtful to them, in retarding their growth, &c.; it haſtens the diſſolution or digeſtion, the formation and ſecretion of their different products. It ſupports the irritability of ſome of their parts, in diſpoſing them to acquire and to retain a due proportion of the principle which cauſes their irritability, namely, oxygen; and in preventing alſo the accumulation of this principle in plants, which may become hurtful to them. It renders their food and juices, &c. more fit for penetrating and paſſing their ſeveral conducting canals, and enables them to diſpoſe of their ſuperabundant portion of fluids, by promoting perſpiration and evaporation. It is ſtill further active in the production of electricity, which has alſo the power of promoting vegetation in a conſiderable degree.

It may likewiſe be obſerved, in addition to the above, that ſenſible heat becomes very uſeful to vegetation in another manner, after the plants have finiſhed the period of their life, or when purpoſely deprived of it; it then occaſions a diſſolution and new combination of their component parts, by fermentation, &c. according to the nature of the vegetable matter, and thereby promotes the preparation and formation of new food for living plants. And the ſame is the caſe with animal matters. By this means it is that manure is in a great meaſure formed. See MANURE.

It is principally in theſe ſeveral ways that heat produces a beneficial influence, in the proceſs of vegetation and the growth of plants.

It is, notwithſtanding, well known, that heat may become prejudicial or even fatal to the conſtitution of plants, when admitted in too great a degree, and for too great a length of time; as it may occaſion a too rapid digeſtion and perſpiration of their nouriſhment, and conſequently an exhauſtion. In caſes of this nature, plants are only capable of recovering by the gradual diminution of the application of ſenſible heat, either by occaſioning a ſlow evaporation of water upon their different parts, or by other means of a ſimilar deſcription. See PLANT and VEGETATION.

HEAT, in *Chemiſtry*. See FIRE.

HEAT *of Birds*. See *Anatomy of* BIRDS.

HEAT, in *Medicine*. This is a ſubject of great importance in the conſideration of the phyſician, whether it be viewed as a cauſe of certain diſeaſes, or as an effect; the regulation of which, in the latter caſe, conſtitutes a material part of the method of cure, and becomes the medium of controul over ſeveral functions of the ſyſtem. We ſhall firſt ſpeak of it as a cauſe of diſeaſe.

Great external heat has been obſerved to be the cauſe of ſevere and fatal diſeaſes, from the earlieſt periods of hiſtory: even in the time of Homer peſtilence was aſcribed to the anger of Apollo, as typical of the ſun: and in all ſouthern climates in our hemiſphere, the ſummer and the autumn are found to be the moſt unfavourable to health. (See EPIDEMIC and HEALTH.) The diſeaſes, too, which are prevalent in hot climates, differ materially in their nature and degree of violence, from thoſe which occur in the more temperate and in the cold ones.

The deleterious influence of heat, on the animal body, as we have already remarked in the article laſt referred to, is of a two-fold nature; ſome of its effects being the reſult of a *direct* operation on the body; but by much the greater number proceeding from its remote or *indirect* operation. We have there ſhewn, at great length, the connection of the moſt frequent and fatal epidemics of former times, with this indirect operation of heat, through the medium of the *miaſmata*, which it engendered in ſwampy countries, in filthy, ill-paved, and crowded towns, in camps, &c., eſpecially when combined with wet ſeaſons: and we have had the ſatisfaction of obſerving the gradual extermination of theſe dreadful maladies, in thoſe cities and countries of the temperate zone, in which improvements in the arts of life have in a great meaſure removed the ſources of miaſmata, upon which the heats of ſummer operated; and of witneſſing, therefore, a total change in the influence of the ſeaſons on the general health. Sir John Pringle long ago ſtated the ſame obſervation with reſpect to the indirect operation of heat. "Great heats," he ſays, "are never ſo much the immediate, as the remoter cauſe of a general ſickneſs:" and he illuſtrates the propoſition by ſhewing, that, in all the campaigns in which he ſerved, although the weather continued long hot, yet no epidemic ever appeared among the troops, until fogs or rains came on, or the army was encamped upon wet ground; as occurred after the battle of Dettingen, in 1743, and again in 1747. "And in the laſt campaign," he adds, "though the heats were great, yet they were the cauſe of little ſickneſs, till the troops were cantoned in the marſhes, where a conſiderable degree of putrefaction and moiſture being joined, the ardent, remitting, and intermitting fevers and fluxes were only the remoter effects of that heat." On Diſeaſes of the Army, part II. chap. 2.

Whether in conſequence of this indirect operation altogether, or partly by inducing ſome change in the animal economy, which prediſpoſes it to fever, it is certain that the yellow fever and the plague only commit their ravages under particular ſtates of heat. The following obſervations, therefore, are peculiarly ſatisfactory to the inhabitants of northern Europe. "In this view," ſays Dr. Blane, in a letter to the Pruſſian ambaſſador, baron Jacobi, "it is eſſential to remark, that this deſtructive (yellow) fever has never been known to appear, except either in tropical climates, or in thoſe ſeaſons in the more temperate climates, in which the atmoſpheric heat has for ſome length of time been equal to the tropical heat, that is, at or above 80° of Fahrenheit's, or 21 of Reaumur's thermometer. This is a fact incontrovertibly eſtabliſhed by obſervation; for there is no inſtance, either in North America or Europe, of the yellow fever appearing, except at theſe degrees of heat, nor of its ſurviving after the atmoſphere had fallen to a lower degree of temperature. This is leſs to be wondered at in North America, where the winters are extremely ſevere; but it holds equally true at Cadiz, Malaga, Gibraltar, and other parts of Spain, where the winters are warm, and where this diſeaſe ſpontaneouſly diſappeared, in degrees of heat equal to the uſual ſummer heats in the north of Europe.

"This is the fact," Dr. Blane proceeds, "which I am deſirous of communicating to the government of Pruſſia, in order to remove any groundleſs fears, with regard to the danger to be apprehended to the ſtates of his majeſty from this infectious diſorder. It is an obſervation which ſeems improbable *à priori*, and can only command belief from the truth of it being eſtabliſhed by a rigid induction of facts. In this reſpect it differs from the ſmall-pox, and other ſpecific contagions, but is *very analogous to the plague*; for it is perfectly aſcertained, that the prevalence of this latter epidemic is confined to a particular range of atmoſpheric heat, both in regard to climate and ſeaſon. We know hiſtorically, that it has never prevailed in England, but in one and the ſame ſeaſon of

of the year, and that it has entirely disappeared, at least as an epidemic, as the winter has come on. A high degree of heat is equally inimical to it; for it has never been known within the tropics, and it disappears or declines in Egypt, as soon as the tropical heats come on at Midsummer. There are certain epidemics, therefore, which have their specific and respective ranges of heat, on either side of which they cannot exist." See Edinburgh Med. and Surg. Journal, vol. iii. p. 385, et seq. where this letter is printed.

Excessive heat, however, is directly injurious to the human constitution, and produces some diseases by a sudden and violent operation, and others by a slower and more protracted influence. Of the former kind are the *ictus solis*, or *coup de soleil*, as the French term it, and acute ardent fevers; of the latter, are various disorders of the liver and alimentary canal, connected with a superabundant secretion of the bile; and some diseases of the skin, such as the "prickly heat," or *sudamine*.

The *coup de soleil*, or insolation, does not appear to arise from the heat of the atmosphere alone, but occurs only when people are exposed to the direct action of the rays of the sun, especially during any labour or active exertion. The intense heat of the sun's rays, acting especially on the head, increases the action of the blood-vessels, and occasions such a congestion in the brain, as to bring on a sort of apoplexy, which has been thus described by Chalmers (see his Account of the Weather and Diseases of South Carolina, vol. i. p. 105.): "The signs which lead to this catastrophe are a full and high-flushed countenance; an universal languor with a drowsiness; some are exceedingly sick, and have retchings to vomit. The head also is so confused and giddy, that the person staggers when he attempts to walk; and so vehement is the circulation in the vessels within and without the *cranium*, that he compares the pulsations of the arteries to the noise of many hammers knocking on his skull. If, in this case, the affected person escapes convulsions or an apoplexy, such a tightness will quickly be perceived about the breast as if that part was girded with cords. A profound sleep soon ensues, during which inspiration is performed in a long, and exspiration in a quick manner, for a small time; but afterward, the breathing being more hurried, is attended with a *stertor* or loud snorting, and inspiration is exerted as it were in a redoubled manner. Presently after, the respiration becomes very slow; and then he so quickly expires, that perhaps this whole scene passes in the space of a quarter of an hour, from the time he began to be disordered." The remedies, which were occasionally successful in removing this state of disease, were, an immediate removal to a cool airy shade, the free use of the lancet according to the strength of the patient, sprinkling his bare head and breast from time to time with cold vinegar, and keeping him in a sitting posture. These instances of fatal insolation, however, are not very common (Moseley on Tropical Diseases, p. 41.); and observation and experiment have afforded abundant proofs that the human body is capable of sustaining much higher degrees of heat in the atmosphere than the hottest climate produces.

It might indeed seem improbable, *à priori*, that a heat so much above the temperature of the human body, as that which occurred in Charlestown, in the summer of 1752, should be borne with impunity; yet Dr. Chalmers assures us that the season was unusually healthy, so long as the weather continued steadily warm and fair. His thermometer, when exposed to the sun, rose in 15 minutes to 120° (the extremity of its scale), and would have been broken if not speedily removed; and, from trials made in cooler weather, Dr. Chalmers has no doubt that the heat of the sun's direct rays was at that time equal to 140°. Suspended in his kitchen, eight feet from the floor and fifteen from the fire, the windows and doors being all open on both sides of the house, the thermometer stood at 115°. "Yet labourers and tradesmen worked abroad as usual; and blacksmiths, as well as cooks, did their business within doors." Several people indeed died suddenly both in town and country; but, on the whole, the season was healthy.

Now, in consequence of an observation, that a dog, accidentally shut up in a sugar-baker's stove, in which the mercury rose to 146, suddenly died, and putrefied rapidly to an extreme degree, Boerhaave was led to deduce some erroneous inferences in respect to the effects of heat on living animals. (See his Elements of Chemistry, tom. i. p. 265.) The cause of death, in this case, was doubtless the mephitic air of the stove, and not the extreme heat; for subsequent experiments have proved that even the human body is capable of existing with impunity, for a considerable time, in a dry atmosphere, heated several degrees *above the temperature of boiling water*. The experiments to which we allude were made by Dr. George Fordyce, sir Charles Blagden, and other gentlemen, in the year 1774, and were repeated by these and other persons both in London and in Liverpool, in the following year. (See an account of them in the Philosophical Transactions, vol. lxv. pp. 114, 463, and 484. See also the particular detail of them under the article *Animal* HEAT.) In the first experiments, the heat of the rooms, in which they remained many minutes, was varied from 119° up to 211°, that is, within one degree of the heat of boiling water. Dr. Dobson and his friends at Liverpool, who repeated the experiments, ventured on the temperature of 224°. But in the second series of trials in London, the air of the apartments was heated to the enormous temperature of 260; and the experimenters had no doubt that they could have sustained a higher degree of heat without material inconvenience. The pulsations of the arteries were increased to about 140 in a minute; but the heat of the body did not rise more than from three to five degrees above the usual state, or 97° of Fahrenheit. These high degrees of heat were much less disagreeable when the body was enveloped in the usual clothing, than when it was exposed naked to the heated air. In the latter case a profuse sweat was produced; but the interposition of the clothes in the former case kept out the external heat in a considerable degree, upon the same principle as it prevents the escape of the internal heat in a cold atmosphere, by being an imperfect conductor.

But although the human body is capable of sustaining these extremely high degrees of temperature for a short time with impunity, experience has shewn that a continued atmospheric heat, of a much lower degree, has a direct tendency to disorder the animal economy, and especially to augment and derange the secretion of the liver; insomuch, that both in hot climates and in the hot seasons of our own latitude, a number of diseases constantly occur, dependent upon the morbid quantity or quality of the bile, and which are therefore denominated *bilious* diseases. In this country the most common of these bilious diseases are the affections of the alimentary canal, which the irritation of the redundant bile appears to occasion. In this way the sickness and bilious vomiting, the diarrhœa with bilious stools, or the combination of these two evacuations of bilious matter, constituting the cholera, are probably produced. These diseases occur principally in the months of August and September, and, during or after very hot summers, they have been observed to attack so many individuals as to be entitled to the epithet of epidemic. Such was the case in London in 1762, and again in 1789, 1790, and 1800. In many habits these bilious

bilious affections assume the form of dysentery, probably from some degree of inflammation being excited in the internal coat of the intestines by the quantity and acrimony of the bile. In all hot countries these complaints are more common and more violent than with us. Indeed in those climates the diseases of the liver itself constitute the largest catalogue of derangements to which the human body, or at least the European habit, is liable; and few individuals spend a large portion of their life in those climates without suffering from them in some degree or other, if they do not bring home a constitution much deteriorated by such attacks. Acute and chronic inflammations of the liver are among the most frequent disorders which that organ suffers in tropical countries (see HEPATITIS); and the most violent and fatal fevers of those countries have been emphatically called *yellow* fevers, from the colour imparted to the skin by the transfusion of bile through the circulating system.

The concurrence of the hot season, in all climates, and the great frequency of these diseases in the hotter regions, indicate a connection between the diseases and the temperature of the atmosphere; and many pleasant theories have been devised, especially upon the principles of chemistry, to account for the superabundant secretion of the liver under the influence of great heat. But we do not deem it necessary to repeat these hypothetical speculations, which, as yet, have failed to reduce the facts to any satisfactory general principle.

Practically, however, experience has taught, in respect to the prevention of these diseases, what reasoning would have suggested *à priori;* that the influence of the inordinate stimulus of heat is best counteracted by diminishing the other stimuli of the living body, which might concur in producing great excitement in the vascular and nervous systems, and in contributing to the unusual distention of the vessels; in other words, by *temperance.* "By keeping the body quiet, and cool within as well as without, the first object of seasoning in hot climates will be attained; which is to moderate the action of the solids, and to diminish the volume and density of the fluids." (Moseley on Tropical Diseases, p. 49.) Hence the same author suggests, that, in a voyage to the West Indies, "after the warm latitudes are reached, it becomes every person to prepare his body, by temperance, for the unavoidable change it must undergo; and to people of a gross habit, and of a strong and full constitution, a mild purge or two, or frequently diluting with a weak solution of cream of tartar in water, if not bleeding, is necessary. The neglect of these precautions occasions violent perspirations, troublesome heats, and eruptions." On the arrival, every excess, more especially in young persons, is dangerous; and temperance in all things is necessary to be observed by men, women, and children. Great resolution, however, appears to be requisite in controlling the desires in climates, where "the brilliancy of the skies, and the levity of the atmosphere conspire to influence the nerves against philosophy and her frigid tenets, and forbid their practice among the children of the sun." But these tendencies have been encouraged by the absurd notions, that people must die of putrid diseases in hot climates unless they embalm their bodies by the assistance of wine, strong liquors, and good living, as it is called—notions which have caused the death of thousands. Those diseases, improperly called putrid, occur most frequently in the young and strong, bearing marks of an inflammatory diathesis; and the symptoms, so called, seem to be the result of the previous high or inflammatory excitement. The avoiding of all spirituous liquors, taking little wine, and drinking principally water, seem to be the most effectual means of escaping the diseases alluded to. "Whatever mode of living," says the author just quoted, "may be proper after people have lived long in hot climates, and when, perhaps, by having been frequently diseased, the inflammatory diathesis of the body is past—while it remains (as it will with some people for many years), those who use water for their common drink will never be subject to troublesome or dangerous diseases." Again, he says, "I aver, from my own knowledge and custom for several years, as well as from the custom and observations of many other persons, that those who drink nothing but water are but little affected by the climate, and can undergo the greatest fatigue without inconvenience." (Loc. cit. p. 57.)

Great heat is likewise injurious, and secondarily productive of much disease, by rendering the body susceptible of the slightest impressions of cold. Many writers, indeed, consider this circumstance as the most pernicious effect of great heat; and Dr. Moseley affirms, that, "however paradoxical it may appear, *cold* is the cause of almost all the diseases in hot climates, to which climate alone is accessary." Although this assertion may be much too general, it cannot be doubted that the influence of cold is most deleterious after the body has been in some measure debilitated by the continued stimulus of heat, and more especially when a free perspiration has been flowing, as nature's expedient for reducing the increased temperature. Hence, in part, the origin of diseases in armies, when they are exposed to rains, or heavy dews, or lie on wet ground, at the close of a hot day, or of a hot season, as stated by sir John Pringle: hence also the common occurrence of severe and fatal fevers after exposure to the night air in the West Indies: and hence, too, the well known effects of similar exposure, in this climate, after being confined for some hours to hot and crowded rooms and theatres. In the same way, the internal application of cold, by copious draughts of water, after violent exertion and during profuse sweating, has not only given rise to violent diseases, but even suddenly destroyed life.

Upon this subject facts are somewhat contradictory, on a superficial view; and some mistaken inferences have been deduced from them, and are still popularly entertained. But the philosophical inquiries of Dr. Currie of Liverpool, appear to have reconciled the apparent contradictions in the facts, and to have established the true principle on which the danger or safety of the action of cold on the heated body depends. The principle is as follows. While the body continues under the influence of a steady heat, and while its power of evolving heat remains entire; that is, while nature's cooling process, perspiration, is not excessive, or the exertions of the body continue to excite the heat, or the external cause of heat remains, and while, on the other hand, no fatigue or exhaustion of the powers of life has occurred, and the ability of re-action continues; then the application of cold is safe and salutary. And it is in the opposite circumstances only that it is dangerous or prejudicial; namely, when a profuse general sweating is rapidly carrying off the heat, when the exertion, or the external heat which excited it have ceased, when the vigour of the system is exhausted by fatigue, and the power of evolving animal heat is thus diminished. Hence, on the one hand, a person heated and exhausted by violent exercise, may expire in consequence of a copious draught of cold water; while, on the other, if he is heated by a quiet sojourn in a hot or vapour-bath, as is the practice in Russia, he may immediataly roll in the snow with impunity. Thus the experimenters in heated rooms, in which the animal heat was excited without exhaustion of the vital powers, passed from the hot rooms immediately into the cold air, even naked, without the least injury or inconvenience, and were very slightly sensible to the action of

cold. Indeed, the circulation was ſo much excited, that it did not ſubſide for two hours; on which Dr. Fordyce remarks, "that the tranſition from very great heat to cold is not ſo hurtful as might be expected, becauſe the *external circulation is ſo excited, as not to be readily overcome by the cold.*" This is correctly true. Hence we have already deprecated that popular, but moſt erroneous practice, of waiting *to cool* before leaving a hot and crowded room; whereas, if we depart while "the external circulation is ſtill excited," while *we continue in a glow of warmth*, and, either by exerciſe in the air, or by a warm covering, *keep up that warmth*, and glow until we arrive at home, no ill conſequences can enſue. The ſenſe of chilline ſs, in thoſe caſes, is the index of danger; and where that is prevented, we believe no hazard can be incurred. Dr. Currie has juſtly remarked, that cold is pernicious, not becauſe we *are hot*, but becauſe we are cooling, *after having been hot*. See COLD.

Of Morbid Heat.—By morbid heat, we mean that augmentation of the natural heat of the body, which is an effect, or one of the ſymptoms, of thoſe various and important diſeaſes which have been thence denominated *febrile* and *inflammatory*; the former term coming from *febris, ferveo, to be hot*,—the latter from *flamma, a flame*. (See FEVER.) The regulation of this febrile heat conſtitutes one of the moſt potent means of curing and alleviating thoſe diſeaſes; and the knowledge of the juſt principles upon which it may be conducted, forms one of the moſt valuable additions to medical ſcience that the laſt half century has produced. We are the more anxious to preſs this ſubject on the attention of our readers, becauſe, although the ſolidity of thoſe principles is eſtabliſhed upon a foundation as ſure as the operation of almoſt any remedy that is employed, ancient prejudices, founded on no better grounds than the old humoral pathology, continue to impede the progreſs of the practice among the people at large, and even to deter many *routiniſts* in the profeſſion from adopting it.

Without aſſuming any theory relative to the origin of animal heat, our knowledge of the nature of which is extremely imperfect, we muſt admit its connection with the circulation of the blood, and its reciprocal influence upon that function, as a matter of obſervation. Diſtention of the ſuperficial veſſels, with redneſs and increaſed pulſation, is invariably conjoined with increaſed heat;—collapſe and paleneſs of parts, with diminiſhed temperature. And, reciprocally, the application of external heat increaſes the action of the blood-veſſels, and the diſtention of vaſcular parts with blood; the abſtraction of heat (or what is commonly called the application of cold) diminiſhes the action of the veſſels, and occaſions a paleneſs and ſhrinking of the fleſhy parts. It muſt be obvious, then, that the regulation of the animal temperature, which is in our power, becomes an inſtrument of great efficacy in modifying other functions of the living body, which are connected with the ſtate of the circulation.

Now, in a ſtate of health, there is a pretty regular balance between the generation of heat, and its abſtraction from the body, ſo that it remains ſteadily about the ſame temperature of $97\frac{1}{2}^{\circ}$ or 98° of Fahrenheit's thermometer. If the heat be augmented from exerciſe or other cauſes, the cooling proceſs of perſpiration and evaporation ſpeedily reduces it to the ſtandard degree. Febrile heat is al o generally abated by ſweating, eſpecially when it is moderate: but when it is conſiderable, (and it often riſes to 102°, ſometimes to 104° and 105°, or in ſcarlet fever even higher, if the obſervations of ſome writers be correct,) the ſecretion of perſpirable matter is prevented; juſt as the ſecretions of other organs are ſuppreſſed during a high inflammatory action of their veſſels. In ſuch a ſtate, then, the augmented heat contributes to keep up the inflammatory conſtriction of the veſſels; the two conditions mutually ſupport each other; and whatever aids the accumulation of heat, neceſſarily augments the inflammatory, or febrile action of the blood-veſſels, in other words, aggravates the febrile diſeaſe.

Let us compare, then, the practice of the humoral pathologiſts, the diſciples of Galen, who upheld his doctrines for thirteen centuries, with that of the modern ſyſtem, which experiment, and not hypotheſis, has eſtabliſhed. In common fever, when the heat of the patient is accumulated in and about him by every means; as by a load of bedclothes, a cloſe unventilated room, cloſed curtains, and a fire; when nothing that is cold is allowed to enter his lips, in ſpite of his inſtinctive craving; and when the inflammatory action of the veſſels is farther hurried by wine, and bark, and aromatic cordials; when ſuch treatment is adopted, every ſymptom of the diſeaſe is aggravated. Congeſtion of blood in the head, and with it, increaſe of head-ach, delirium, reſtleſſneſs, or coma, enſue; the whole ſtate of ſenſation is diſtreſſing and irritating to the patient; the tongue is loaded, the ſtomach and alimentary canal are completely deranged, the thirſt moſt urgent; and, after a few days, exhauſted by this unceaſing irritation, the patient ſinks under all the ſymptoms of what is called putreſcency. When ſuch practice is purſued in ſmall-pox, or ſcarlet fever, theſe ſymptoms of putreſcency become ſtill more ſevere, and gangrenous appearances take place, ſoon to be followed by death. The ſmall-pox, indeed, afford a ſtriking proof of the pernicious operation of external heat in aggravating diſeaſes of this claſs: for, the eruptions on the ſkin may be multiplied at pleaſure, merely by exciting heat in the ſkin. Of this fact, ſome deſigning men are ſaid to have availed themſelves, in order to extend their reputation among the ignorant, and to have pretended to draw the diſeaſe to one ſpot, by covering the part with a warm plaſter, under which a large crop of puſtules never failed to appear.

On the other hand, when the regulation of the morbid heat is accompliſhed, according to the principles which have been eſtabliſhed by the experiments of Dr. Currie and others, febrile diſeaſes aſſume a much milder type, and many of the moſt diſtreſſing and dangerous ſymptoms are warded off. We have ſtood over a patient in ſcarlet fever, while the proceſs of reducing the heat by cold-waſhing was going on, and have had the ſatisfaction, in the courſe of a few minutes, of witneſſing the great amelioration of the ſymptoms thus produced. The extreme heat and dryneſs of the ſkin have been followed by a grateful coolneſs, and a gentle perſpiration; the tongue, before dry, has become moiſt, and the ſenſation of thirſt has been removed; the delirium has diſappeared, and the head-ache been greatly relieved; the dull, ſuffuſed, and anxious countenance has ſpeedily aſſumed the calm and clear expreſſion of agreeable feelings; and the general reſtleſſneſs been immediately followed by a diſpoſition to calm ſleep. When, in addition to this diminution of heat, the internal cordials are ſuperſeded by cool aqueous drinks, diluent and aperient medicines, and vegetable nutriment; and when the patient is ſurrounded by freſh cool air, the whole character of the fever is often changed; and if ſo treated from the beginning, it may paſs on ſafely and mildly to its termination, without exhibiting any of thoſe ſymptoms of malignancy and putreſcency which would have occurred under the oppoſite method of treatment. We know that the ſuperior ſucceſs of Sydenham's practice in the ſmall-pox, over that of his contemporaries, originated in the *cool* treatment which his ſagacity led him to introduce; and that the moſt ſucceſsful modern inoculators of that malady have

adopted a ſimilar ſyſtem. We know, too, that the ſcarlet fever prevailed, like a plague, in its moſt fatal forms, in many parts of Europe, under the method of treatment formerly purſued. (See Willan, on Cutaneous Diſeaſes, p. 3.) It is unneceſſary to add, that in acute local inflammation, in general, the abſtraction of heat is, next to the removal of the diſtention of the veſſels by blood-letting, one of the moſt effectual means of reducing the inflammatory action. See INFLAMMATION.

It remains for us to ſay a few words in reſpect to the circumſtances under which the great abſtraction of morbid heat may be unſafe: for although the abſurdity of the humoral theories may be conſpicuous, and the danger of repelling the *materies morbi* from the ſurface to the internal parts may be gratuitous and viſionary in a great degree; yet there are varieties of diſeaſe and ſtates of the conſtitution in which danger may be incurred, and caution is requiſite. The principle already ſtated, when ſpeaking of the influence of cold on the body heated during health, is applicable in the caſe of this morbid heat. The great and ſudden abſtraction of it in febrile diſeaſes is only unſafe, when the heat is not preternaturally great; when it is not ſteady, but fluctuating, or alternating with chills; when it is only partial; when it is accompanied by general or profuſe perſpiration; and even when the heat, as meaſured by the thermometer, is preternaturally great, if the patient be acutely ſenſible to impreſſions of cold on the ſurface, the application of cold will be unſalutary. In a word, whenever the faculty of cooling heat is not ſteady, or is eaſily interrupted; when the arterial action is not powerful, although quick; and the *vires vitæ*, or energies of the ſyſtem, have been enfeebled by the continuance of diſeaſe, much ſweating, or other cauſes; under theſe circumſtances, and theſe only, is the ſudden application of cold hazardous. When there is any local inflammatory diſeaſe in any internal organ, its operation is leſs ſalutary, but there is reaſon to believe not dangerous.

The preceding obſervations apply principally to the ſudden abſtraction of heat in febrile diſeaſes, by means of cold water *affuſed* on the body, or uſed in the way of *ablution*: but the neceſſity of avoiding the accumulation of the morbid heat by *coolneſs* in the air of the ſick-room, in the bed, and in the general regimen of the patient, is requiſite in the early ſtages (after the heat is eſtabliſhed, and the chills have entirely ſubſided) of all fevers, and is ſalutary, we believe, through the whole courſe of the majority of them. (See COLD *as a Remedy*; and *the Cure of* FEVER.) Thoſe who wiſh for more ample information on this important ſubject, may conſult Dr. Currie's Medical Reports on the Effects of Water, &c. Dr. Stock's Medical Collections on the Effects of Cold, 1805. Dr. Irvine's Obſ. on the Diſeaſes of Sicily, 1810. Dr. Ruſh's Medical Inquiries. Dr. Kinglake's Treatiſe on Gout, &c.

HEAT, *Prickly*, an eruption of *papulæ* or pimples, almoſt univerſally affecting Europeans on their firſt ſettlement in tropical climates.

The "prickly heat" is placed by Dr. Willan as a variety of Lichen, the ſecond genus of the Order of *Papulæ*, and denominated Lichen *tropicus*. It appears without any fever or preceding diſorder of the conſtitution, and conſiſts of numerous pimples, about the ſize of a ſmall pin's head, and elevated ſo as to produce a conſiderable roughneſs of the ſkin. The papulæ are of a vivid red colour, and often exhibit an irregular form, two or three of them being in many places united together: but no redneſs or inflammation appears on the ſkin in the interſtices of the papulæ. The eruption ſpreads over thoſe parts which are uſually covered with the clothes, as the neck, breaſt, arms, legs, and inſide of the thighs. It does not appear on the face, except on the upper part of the forehead contiguous to the hair; nor is it ever found in the palms of the hands, ſoles of the feet, or on the hairy ſcalp. When perſpiration is very copious, ſmall pearly veſicles, containing a limpid humour, are often intermixed with the *prickly heat*, more eſpecially on the breaſt and about the wriſts: but they terminate in ſcales, having no diſpoſition to ulcerate, though violently ſcratched. Some authors have likewiſe mentioned an appearance of ſmall white tubercles, or wheals, interſperſed with this eruption.

An intolerable itching attends the *prickly heat*, together with a frequent ſenſation of pricking, as if a number of needles were piercing the ſkin; whence the diſorder has derived its name. This often takes place ſuddenly, Dr. Winterbottom remarks, after drinking a diſh of tea or any warm liquor, ſo as to cauſe the perſon affected to ſtart from his ſeat. The eruption is generally ſtationary, but is always increaſed by increaſe of heat. Thus wearing flannel or other clothes, too thick and warm for the climate, greatly aggravates it; and in the hotteſt months, it occurs more or leſs to many people every year, to natives as well as ſtrangers, according to Dr. Hillary. It generally goes off in a few weeks, leaving the cuticle ſcurfy, which afterwards falls off in ſmall white ſcales. Perſons of a fair complexion, with red hair and a ſoft ſkin, are moſt liable to this eruption, and have the greateſt quantity of it: thoſe who are of a dark complexion either remain wholly free from it, or are affected very ſlightly. In general the complaint becomes leſs frequent and troubleſome as ſettlers become habituated to the climate, and at length entirely diſappears.

Dr. Winterbottom remarks, that "the prickly heat is, in general, conſidered as a ſalutary eruption, whence we are cautioned not to repel it from the ſkin by cold or other external applications. Such a repulſion cannot, however, be eaſily effected: it is certainly not produced by bathing, which has been hitherto thought highly prejudicial. A vivid eruption of the prickly heat is a proof that the perſon affected with it is in a good ſtate of health, although its abſence does not always indicate the contrary. The ſudden diſappearance of it, which frequently happens, is rather an effect than a cauſe of internal diſorder, as of fever, or any ſlight complaint of the ſtomach: in the latter caſe, a temporary ſtimulus applied to the ſtomach, as by ſpirits, tea, or other warm liquids, has the power of reſtoring the eruption. Its appearance on the ſkin of perſons in a ſtate of convaleſcence from fevers, &c. is always a favourable ſign, indicating the return of health and vigour. Various means," Dr. Winterbottom adds, "have been employed to alleviate the itching and tingling of the prickly heat: the favourite remedy at Sierra Leone is the juice of limes rubbed on the ſkin, which, however, has no conſiderable effect. I have found it of moſt advantage to uſe a light, cool dreſs, and to avoid the drinking of warm liquors."

The earlier writers on tropical diſeaſes agree in recommending a cool regimen and temperance, eſpecially in the uſe of ſpirituous or vinous liquors; but they all harp upon the old humoral ſtring, and ſpeak much of the danger of repelling the eruption, and the advantage of "*encouraging* the eruption by taking ſmall warm liquids and nouriſhments, as gruel, tea, coffee, wine, whey, broth, and plain meats." (Hillary.) In this ſtyle they formerly treated of ſmall-pox and ſcarlet fever: but unbiaſſed obſervation has exploded theſe opinions; and we doubt not that the remarks of Dr. Winterbottom are correct.

Dr. Cleghorn has deſcribed a ſimilar eruption, which is called the Raſh, or Summer Raſh, or prickly heat, in the iſland

iſland of Minorca; but its ſymptoms are by no means ſo violent and diſtreſſing as thoſe of the Lichen tropicus. Dr. Cleghorn conſiders this diſeaſe as the *ſudamina* of the Romans, and the ἱδρωα, *hidroa*, of Hippocrates. Dr. Willan, however, obſerves that "the term Hidroa is uſually applied by the Greek phyſicians to an eruption of miliary puſtules:" and thinks that the more appropriate terms uſed by them are lichen, eczema, or eczeſma. The eſſera of the Arabians comprizes the nettle-raſh, prurigo, and ſome other eruptions, beſides the prickly heat. See Hillary on the Diſ. of Barbadoes.—Moſeley on Tropical Diſeaſes.—Cleghorn on the Diſ. of Minorca.—See alſo Dr. Willan's learned work on Cutaneous Diſeaſes, which contains a deſcription of the diſeaſe by Dr. Winterbottom, &c.

Heat *of Mines*, in *Geology*. Among early writers, great ſtreſs was laid on the temperature of deep mines as a geological phenomenon; and accordingly Dr. Woodward gave this ſubject particularly in charge to the travelling obſervers whom he employed, "Method of Foſſils," p. 103. Repeated obſervations have however ſhewn, that the preſence of different minerals, at ſimilar depths, do not ſenſibly affect the temperature of excavations therein. M. Werner, in the tranſlation of his "New Theory of Veins," p. 171, ſays, "I have likewiſe found that what has been ſaid of the great heat obſervable in mines of pyrites, is totally void of foundation."

Heat, in *Smithery*, &c. See Iron.

Heat is alſo uſed, in reſpect of race-horſes, for the exerciſes to be given them by the way of preparation, &c. Two heats in a week are reckoned a juſt meaſure for any horſe, of what ſtate or conſtitution ſoever. The jockeys lay it down as a rule, that one of the heats be given on the ſame day of the week whereon the horſe is to run his match; and this is to be the ſharpeſt heat.

Heat *of Vegetables*, in *Vegetable Phyſiology*, is evinced by the more ſpeedy melting of ſnow when in contact with their leaves or ſtems, compared with what is lodged on dead ſubſtances, provided the preceding froſt has been ſufficient to cool thoſe ſubſtances thoroughly. Mr. Hunter appears to have detected this heat by a thermometer applied in froſty weather to the internal parts of vegetables newly opened, but ſuch an experiment may be liable to ſome fallacy.—That a certain portion of heat is neceſſary to the life and vegetation of every plant, is evident to the ſlighteſt obſervation. It is not only a neceſſary ſtimulus to its conſtitution, for the purpoſes of vegetation, but its total deprivation is fatal to the vital principle. A determinate portion of heat is eſſential to the health and well-being of every plant, but this degree is remarkably different with reſpect to the plants of different climates. The vegetable productions of the tropics are as effectually killed by a freezing degree of cold as all plants are by a boiling heat, and exhibit nearly the ſame appearance. The vegetables natural to cold climates, on the contrary, are able to ſupport a much greater degree of cold without injury, at leaſt while in a torpid ſtate. When their vital principle is rouſed, and their buds begin to expand, they become vaſtly more ſenſible. This may be ſeen every ſpring, more or leſs, in trees whoſe buds are formed to ſuſtain the ſevereſt froſt, even of a Lapland climate, but ſome of which, even in our own, are liable to ſuffer from a comparatively ſlight recurrence of cold after their buds have once begun to burſt. Hence the difficulty of naturalizing many trees and ſhrubs, of America for inſtance, in climates apparently much milder than their native ones.

The growth of moſt plants may be accelerated by artificial heat, (ſee the article Forcing,) and Mr. Knight has ſhewn that plants acquire habits with regard to heat which are a deciſive proof of their vitality. A peach-tree that has been forced, if expoſed to the open air in the following ſeaſon, expands its buds prematurely to inevitable deſtruction. In general, however, plants which have been forced require a ſtronger degree of heat than is natural to them, in order to continue in health. The effect of heat upon them is in proportion to the degree of cold to which they have been accuſtomed. See Circulation *of Sap*.

If it be ſo difficult to account for the ſpontaneous production of heat in animal bodies, as all phyſiologiſts have found, it muſt be much more ſo to account for the generation of vegetable heat, yet one cannot but ſuſpect that the cauſes of each may be ſimilar. Light and the atmoſpheric air at leaſt are known to be eſſential to the vital functions of both. The moſt remarkable inſtance of heat in plants upon record, is what is related of the *Arum maculatum*. Lamarck ſays, in his *Flore Francaiſe*, v. 3. 538, "that when the flowers are in a certain ſtate of perfection, the ſpadix is ſo hot as to ſeem burning, and not at all of the ſame temperature as the ſurrounding bodies. This heat remains but for a few hours." This ſame author obſerved this phenomenon in the white-veined variety of the plant in queſtion, which is certainly very little different from our common *Arum*. Mr. Senebier noticed that this heat began when the ſheath was about to open, and the ſpadix juſt peeping forth, and that it was perceptible from three or four o'clock in the afternoon till midnight. Its greateſt degree was 7° of Reaumur's ſcale above the heat of the atmoſphere, which at the time of his obſervation was about 14 or 15 of that thermometer.

Heath, *Mountain*. See Saxifraga.

Heath, *Low-pine*. See Coris.

Heath-*cock*, in *Ornithology*. See Grous and Tetrao.

Heath-*peaſe*, in *Botany*. See Orobus.

Heath, in *Agriculture*, a well-known plant, frequently met with on extenſive tracts of poor common and moor land. It is conſtantly found growing on ſuch deſcriptions of land as have an indifferent quality. A tilly ſoil, according to the Survey of the County of Inverneſs, is that in which it moſt delights; ſand being too weak to carry a plant that demands ſuch a quantity of ſupport; while deep moſs is too much ſurcharged with moiſture to render its growth vigorous. There is, however, a ſtratum of moſs on the ſuperficial parts of grounds, where it is met with in abundance, but the layer in theſe caſes is thin; being formed by the leaves and other deciduous parts of the plant itſelf, in the courſe of time, and has invariably a ſubſtratum of till, which is more or leſs barren in its nature, placed below it. It has been further ſuggeſted in the above work, that "the region peculiar to heath and the altitude at which it grows, is not great, conſidering the frequency of its appearance in northern latitudes. While the warm valley on the one hand, which enjoys the fertilizing influence of a placid ſtream, and of a powerful ſun, is too rich a ſoil for this plant; the higher ſummit of the mountain is, on the other hand, too cold, too barren, and too much expoſed, to be the favourite ſoil or climate of heath. Fungous moſs, the moſt barren of all plants, and the leaſt capable of affording nouriſhment to cattle, occupies theſe ſummits. The heath grows midway up the hill, while the ſkirts and the vallies below are deſtined for graſs and corn. Thus, the very covering given to the mountains, demonſtrates the benignity of Providence: what is neareſt to the habitation of man, is beſt adapted to his ſupport; what is neareſt and moſt acceſſible to his cattle, affords

affords them moſt nouriſhment; and the leaſt productive part of his ground is removed to the greateſt diſtance."

It is ſtated in addition, that "in ſome low plains of till, or gravel, or ſand, where the ſurface is too flat or too diſtant from the higher ground to admit of brooks, the ſurface is covered with a ſhort ſtunted heath. If till be the ſubſoil, the heath is mixed with ſome piles of coarſe graſs, by means of the rains and dews, which do not haſtily loſe their effect; but if the gravel or ſand be pure, having little or no mixture of earth, the rain filters through before it has had time to produce any effect on the ſurface; and the dews are too feeble and tranſient a refreſhment, to counteract the ſterility of the ſoil. In theſe ſituations, nothing is to be ſeen but one continued field of heath; becauſe the ſoil is the moſt barren of all, and moſt difficult to be rendered productive. Even Scotch firs, it is remarked, which grow almoſt in any ſoil, will not thrive in it, of which inſtances might be given in different counties."

It is an extremely intereſting conſideration, whether taken in a national or individual point of view, that the progreſs of agriculture, and the ſtrenuous exertions of man, are ſpeedily leſſening the domination of this barren plant in numerous diſtricts of the kingdom. It is now well known, however, that ſuch ſoils as are prone to the production of this vegetable, though brought into a ſtate of cultivation with the utmoſt care, are conſtantly diſpoſed, under any ſort of neglect, to throw up the ſame ſort of plants by which they were previouſly coated. On this account it is, that neither cattle, ſheep, nor any other ſort of live ſtock, are capable of keeping down the heath, where the exercions of man are not carried on in combination with them.

It is found that ſheep, in many ſituations, are fond of cropping this plant, and that, in the county of Norfolk, they are occaſionally obſerved to ſucceed better, as well as to be more free from diſeaſe, when kept in ſituations where it prevails than in other caſes. And in a paper contained in the firſt volume of the Farmer's Magazine, a plan is propoſed for converting it into winter fodder, in ſituations where green crops are not capable of being raiſed in that intention, to any conſiderable degree; as from long experience, it is well known to compriſe a wholeſome and palatable ſort of food when conſumed in the green ſtate, there can be little doubt of its being equally ſo, when cut and dried at a proper ſeaſon, and duly preſerved. Beſides, it is aſſerted that the practice has long prevailed in Sweden, the heath harveſt in ſome parts of that country being as regular, and as much regarded, as the corn harveſt in the moſt fertile provinces of the ſtate. Long experience has convinced the natives of its value, and furniſhed an example that ought not to be loſt ſight of by other nations, which are ſimilarly ſituated in regard to ſoil and climate. It affords in that kingdom, a bulk and eſſential article of winter fodder, in various places where no other ſort can be procured. While kept properly down and in the young ſtate of growth, it may with facility be cut over or mown with a ſcythe for the purpoſe; but under the contrary circumſtances it will require a much ſtronger tool. It is adviſed to be mown or cut over at the period when the flowers are fully expanded, as it will then be in the moſt nutritious ſtate. And the work ſhould be performed as much as poſſible in dry weather, being immediately put into a ſort of cocks or heaps, where it may continue for a week or ten days, being then placed in large ricks, and permitted to remain until it may be found convenient to have it conveyed to the places where it may be wanted as a winter food. In this way it may be found of great utility to ſheep farmers in particular ſituations.

It has alſo been found uſeful in other points of view, as in thatching different ſorts of farm buildings, conſtructing brooms, and various other purpoſes.

Heath-*plough*, is an implement contrived for the breaking up of lands covered by heath. In the Repoſitory of the Society of Arts in the Adelphi, there are preſerved, for public inſpection, models of two heath-ploughs, *viz.* by Mr. Ringroſe, Claſs I. N° 4, deſcribed in volume i. of the Society's Tranſactions, p. 303, and in Bailey's Machines, vol. i. p. 26: and another with a curved coulter, by Mr. Matthew Peters, Claſs I. N° 39, vol. i. p. 312, Bailey's Machines, vol. ii. p. 11, and Doſſie's Memoirs, vol. iii. p. 266. At the Woburn ſheep-ſhearing 1810, Mr. Robert Salmon produced a plough for preparing heath land for planting, which was tried in preſence of a committee, and rewarded by the noble duke's premium for implements.

Heath, Benjamin, in *Biography*, an eminent claſſical ſcholar, was by profeſſion a lawyer, and held the poſt of town clerk of Exeter. He publiſhed, in 1740, "An Eſſay towards a demonſtrative Proof of the Divine Exiſtence, Unity, and Attributes," which was eſteemed one of the beſt defences of Dr. Clarke's hypotheſis. In 1762, he publiſhed, as the reſult of twelve years labour, "Notæ ſive Lectiones, ad Tragicorum Græcorum veterum, Æſchyli, Sophoclis, Euripidis, quæ ſuperſunt Dramata, deperditorumque reliquias." This was printed at the Clarendon preſs, and probably, on account of it, he received a diploma from the univerſity of Oxford, creating him doctor of laws. In 1763, he wrote a pamphlet, on the exciſe duty on cyder and perry, which was ſuppoſed to have had great influence in procuring the repeal of that tax; and in 1765, he gave the public "A reviſal of Shakſpeare's text, wherein the alterations introduced into it by the more modern editors and critics, are particularly conſidered." Gen. Biog.

Heath *Point*, in *Geography*, a cape on the S. E. extremity of the iſland of Anticoſti, in the gulf of St. Laurence. N. lat. 49° 6'. W. long. 62°.

HEATHEN. See Gentile and Pagan.

HEATHER, or Heythier, William, in *Biography*, was born at Harmſworth in Middleſex, and having been received as a choriſter in Weſtminſter abbey, when his voice broke, he purſued the ſtudy of muſic as a profeſſion; but though he became one of the gentlemen of the chapel royal, he ſeems to have diſtinguiſhed himſelf neither by his vocal nor inſtrumental performance, or by his muſical compoſitions; but has had his name recorded as the friend and agent of our learned and excellent antiquary Camden, who having formed the deſign, a few years before his deceaſe, of founding a hiſtory-lecture or *profeſſorſhip*, in the univerſity of Oxford, diſpatched his friend Heather on a miſſion thither, with the deed of endowment properly executed, and addreſſed to the vice-chancellor Dr. Piers. It was in conſequence of this embaſſy that Heyther obtained his degree of doctor in muſic, with little expence and trouble; and perhaps it was in gratitude for the kindneſs he received from the univerſity upon this occaſion, as well as in imitation of his learned friend Camden, that he endowed the profeſſorſhip, which is both theoretical and practical. At the time of this endowment, in order to promote the practice of the art, "he gave to the muſic-ſchool an harpſicon, a cheſt of viols, and divers muſic-books, both printed and manuſcript."

It is the more likely that Heyther was inſtigated by Camden to found this profeſſorſhip, who had himſelf been a choriſter at Magdalen college, Oxford, and may be ſuppoſed to have ſtill retained a love for muſic; and that Camden had a great aſcendency over him, may be inferred from the intimate friendſhip which had long ſubſiſted between them. Their ſeveral employments reciprocally obliged them

to reſide in Weſtminſter: for Camden was maſter of Weſtminſter-ſchool, and Heyther a gentleman of the king's chapel. In town they reſided under the ſame roof; and, in 1609, when a peſtilential diſeaſe had reached the houſe next to that of Camden and himſelf, by which Camden was afterwards infected, he retired to the reſidence of his friend Heyther at Chiſlehurſt, and by the aſſiſtance of Dr. Giffard, his phyſician, was cured. But of his friendly regard for Dr. Heyther, he gave ample teſtimony at his deceaſe, by appointing him his executor, and bequeathing to him and his heirs an eſtate of 400*l.* a year, for the term of ninety-nine years, he and they paying to the hiſtory-profeſſor 140*l.* per annum; at the expiration of which term, the eſtate was to veſt in the univerſity.

It is more than inſinuated by Ant. Wood, that Heather was not ſufficiently ſkilled in counterpoint, to have compoſed the anthem which was performed as an exerciſe for his degree. But as this ſtory probably originated from envy, and has been ſince propagated without ſufficient proof, it now only merits notice, in order to put readers who may meet with it elſewhere, on their guard, in giving it credence. Who knows now what the anthem was which Heather had performed for his degree? The ſtory ſeems not to have been circulated till after the deceaſe of Orlando Gibbon, who could alone have confirmed or confuted it: as it is poſitively ſaid that a MS. copy of Heather's exerciſe has been found with the name of Orlando Gibbon prefixed to it, without acquainting us how it was known to have been performed as Dr. Heyther's exerciſe, who being brought up in one of our beſt choirs, and qualified for admiſſion as a gentleman of the king's chapel, could not be ignorant of muſic, and who by the muſical profeſſorſhip which he founded, manifeſted his zeal for the honour and progreſs of the art.

Heyther had been ſworn a gentleman of the chapel royal in 1615. And according to Ant. Wood, he and Orlando Gibbon were ſuffered to accumulate the degrees both of bachelor and doctor in muſic; and on the 18th of May, 1622, were both created doctors together.

Orlando Gibbon died of the ſmall-pox at Canterbury 1625, where he was attending the ſolemniſation of the marriage of Charles I. with Henrietta of France, for which occaſion he had compoſed the muſic, and Dr. Heyther died in 1627, and was buried in the broad or ſouth aiſle, joining to the choir of Weſtminſter abbey.

There is now in the muſic-ſchool at Oxford, a picture of Dr. Heyther in his gown and cap, and he well merits a place there, not only as a graduate, but a benefactor to that univerſity.

Heather, in *Rural Economy*, a name commonly applied to heath in moſt of the more northern parts of the kingdom, and particularly in Scotland. See Heath.

Heather-*roof*, that kind of roof employed in building, which is thatched over or covered with heather or heath, inſtead of ſome other material. It is recommended, as well adapted to buildings of the farm deſcription, by the writer of the Survey of the County of Argyle, in Scotland, on the principle that it does well with timber of the ordinary ſort, is capable of being procured for a trifle, laſts nearly as long as ſlates, and affords leſs trouble in the repairs. It is aſſerted that a roof of this material, when well put on, will laſt one hundred years, provided the timber continues good that length of time. And it is ſtated, that formerly moſt of the churches in the above county were covered with this ſort of roof; likewiſe, that heather-roofs are frequently met with in the diſtrict of Cowal, and that there are a few of them in Kintyre.

It is ſuggeſted, that in the "great rage for deſtroying heath it would be wiſe to ſave, at leaſt, as much of the proper kind as might be needed for thatching." The writer indeed conſiders it "aſtoniſhing, that, in a country where heather abounds, thoſe roofs are not more common. They are," he aſſerts, "indeed heavier than ſtraw roofs; but by making them a little ſteeper, and placing the couples a little nearer, than in our ordinary roofs, the moſt of the weight will be thrown on the walls; which, if made, as they ought to be, of ſtone and lime, will not feel the burden."

This ſort of material may certainly be employed with advantage as a covering for ſmall houſes and other buildings, where other kinds of ſubſtances cannot be procured, except at great expence; but at the ſame time it is very inferior to ſlate and other ſimilar matters in forming the coverings of ſuch erections. See Farm *Buildings*.

Heathy Land, that deſcription of waſte moory ground which is principally covered with the heath plant. There are vaſt tracts of this kind of land in theſe kingdoms; which, in their preſent ſtate, are merely appropriated to the ſupport of a few ſheep, but which, under proper cultivation, would afford uſeful crops of ſeveral different ſorts, and of courſe become of much greater utility and advantage.

Lands of this nature are, notwithſtanding, found to vary greatly in the qualities of the ſoil, as well as the abundance of the heathy material by which they are covered. They muſt of conſequence differ much in the means of cultivation which are neceſſary to be employed according as theſe different circumſtances are more or leſs predominant. Where ſuch lands are thickly ſtudded with this ſort of plant, it has been adviſed on the ground of experience, as the beſt mode of proceeding in the intention of getting ſpeedily quit of it, to have recourſe to the proceſs of paring off and burning the ſurface, as under this management the land is at once reduced into a proper ſtate for the reception of crops; while, under other modes of treatment, much time is not only requiſite for the complete decay of the heath, but the ſoil is preſerved in far too open and light a condition for the growth of moſt ſorts of crops, during the whole period. Immenſe diſtricts of land of this quality have, within theſe late years, been brought into cultivation in this manner with the moſt perfect ſucceſs and benefit. In moſt caſes, however, it is eſſential that the paring ſhould be executed in as thin a manner as poſſible, ſo as effectually to remove the heath, and that a proper ameliorating ſyſtem of cropping ſhould afterwards be purſued. And in a great number of inſtances it will be the moſt adviſable plan to reſtore ſuch lands as ſpeedily as the nature of the undertaking will permit to the condition of graſs in the view that they may be fed with ſheep, or ſome other light ſort of live ſtock.

Mr. Wedge, on poor heathy land, alſo found that ſuch parts as were pared and burned, were far ſuperior in the crops to thoſe which had not the benefit of that proceſs. Many other farmers are, likewiſe, decidedly of opinion that the moſt advantageous ſyſtem of practice, in many caſes, is that of having the heathy material at firſt properly reduced by fire.

In ſome inſtances, notwithſtanding, ground of this deſcription, where the heath is not too ſtrong or thick in its growth, may be brought into a ſtate of culture without undergoing the operations of paring and burning; which is often tedious, as well as attended with conſiderable expence.

There is ſcarcely any point of this intereſting ſubject that demands more regard than that of the proper modes of cropping after they have been broken up at firſt. On poor gravelly heath, Mr. Wright of Rutlandſhire has ſtrongly recom-

recommended the mode detailed below: "firſt year pare and burn, and ſow with turnips; ſecond year, barley; then immediately after the barley crop, on once ploughing, harrow in winter tares, to be mown for ſoiling ſtock of all kinds upon the ſame ground; the fence to be kept ſhifting back as the piece gets cleared. It may be begun moſt probably about the third week in May, and continued till the ſeed in the pod is nearly full, perhaps in the beginning of July; what is then unconſumed ſhould be mown and made into hay, which is excellent; then directly on one ploughing ſow with turnips without manure, though it would certainly be a valuable addition, if attainable; after turnips, barley laid down with ſeeds, either for one year or permanently." It is obvious that, in this method of proceeding, there are five valuable crops, and the land laid down with ſeeds in three years and about two months; and each crop may be expected to be a good one either with fallow or manure.

It is conceived, that under this plan the land can neither get foul, ſtale, or exhauſted. Tares are by many thought an inconſiderable crop, but they are ſuch perſons as have not been in the habit of cultivating them. All things conſidered, it is ſuppoſed a matter of doubt whether a farmer can cultivate a more beneficial crop from the ameliorating quality of ſmothering. Corn thrives remarkably after them. Some may, it is conjectured, object to corn crops coming ſo ſeldom; to this it is anſwered, that the moſt corn ſown, is not always the moſt reaped, but the very reverſe; for theſe two corn crops will, at a certainty, produce more grain than if every crop had been of that deſcription, while the ground is left in an improved condition inſtead of being left wholly deteriorated.

Upon a poor heath, on a chalky bottom, Mr. Wedge found the mode of cropping detailed below to be highly advantageous:

1ſt year burnt wheat,
2d —— turnips,
3d —— barley,
4th —— ſeeds,
5th —— half-ſeeds, half-peas,
6th —— wheat after ſeeds and peas,
7th —— turnips manured for,
8th —— barley,
9th —— ſeeds,
10th —— half-peas, half-ſeeds.

In this manner of proceeding it is remarked, that half of the ſecond year's ſeeds will be ſown with peas or tares alternately, the wheat crops will conſtantly take the fold, and the turnip ground the dung, which, in general, will ſecure on white land a fair crop of turnips; it is contended that the fold will not afford the ſame effect. The writer conceives that it requires but little to prove the vaſt benefit of burning this kind of land. The ſeventh year after that operation is the firſt period at which dung is at all requiſite, as the land is in no part of this proceſs in a deteriorated condition. In light heathy ſoils, the advantage of the uſe of clay and marle is very conſiderable, when applied in tolerably large quantities, as from fifty to ſixty loads or more to the acre. Without ſome application of this nature, that ſort of firmneſs which is neceſſary for the growth of turnips and ſome other crops can ſcarcely ever be attained. See *Waſte* LAND.

It has been ſuggeſted, in conſidering the cultivation of waſte lands of the heath kind, where the tenants have leaſes, and are not able or diſpoſed to the improvement of them, that, as the principal charge is the expence of lime, the proprietor ſhould advance the amount to the tenant free of intereſt for three years; the former to be reimburſed at the termination of that period; the tenant being in return bound, not only to improve the land on a plan to be laid down by the landlord, but alſo to be ſubjected to a certain method of cropping, when the improvement has been effected. By adopting this ſort of arrangement, a great extent of heathy land might ſpeedily be brought into a highly productive ſtate of cultivation.

HEATOTOTL, in *Ornithology*, the name of an American bird, deſcribed by Nieremberg, and called alſo *avis venti*. It is remarkable for a very large and round creſt of whitiſh feathers on its head. Its breaſt is of a browniſh grey; its belly white, and its feet yellow; its tail is round when expanded, and is variegated with black and white; its back and wings are black.

HEAVE, at *Sea*, ſignifies to throw away or fling any thing over-board.

When a ſhip, being at anchor, riſes and falls by the force of the waves, ſhe is alſo ſaid to *heave and ſet*.

To HEAVE *a peek*. See PEEK.

To HEAVE *at the capſtan*, ſignifies to turn it about. See CAPSTAN.

To HEAVE *down*. See CAREENING.

To HEAVE *a flag aboard*, is to hang it out. See FLAG, and SIGNAL.

To HEAVE *a-head*, is to make the ſhip advance by heaving in the cable, or other rope, which is faſtened to an anchor at ſome diſtance before her. *To heave a-ſtern*, is to draw the ſhip backwards by the ſame operation.

To HEAVE *the lead*. See SOUNDING.

To HEAVE *out*, is to unfurl and throw looſe a ſail from the place where it had been rolled and faſtened. The phraſe is more particularly applied to the ſtay-ſails: as, *looſe the top-ſails*, and *heave out the ſtay-ſails*, which is done, in order to ſet or dry them.

To HEAVE *ſhort*, is to draw ſo much of the cable into the ſhip, by means of the capſtan or windlaſs, as that by advancing ſhe will be almoſt perpendicularly above the anchor, and in a proper ſituation to ſet ſail: and to *heave taught*, is to turn about the capſtan, till the rope applied to it becomes ſtraight, and ready for action.

HEAVE-*offerings*, under the *Jewiſh Law*, were things offered up to God, by lifting them up on high.

HEAVE, in *Mining*, ſignifies a *fault* or derangement of the ſtrata, ſee that article. Mr. Farey, from obſerving the worn ſtate of the edges of faults, as well of thoſe which do not derange the ſtrata vertically, or very little, as of thoſe which do ſo in the greateſt degree, infers, that the ſurface of the earth has, for a long time, been ſubjected to a progreſſive *heaving*, like the waves of a high ſea. See Philoſophical Magazine, vol. xxviii. p. 120. and other places in that work.

HEAVED is applied, in Cornwall, to the lateral derangement, with reſpect to the ſurface, which the loads or mineral veins have ſuffered by the croſs flookans or faults.

HEAVEN, CŒLUM, an azure, tranſparent orb inveſting our earth; wherein the celeſtial bodies perform their motions.

The popular notion of heaven, it muſt be obſerved, has various ideas, in the language of philoſophers, divines, and aſtronomers: agreeable to which we may lay down divers heavens; as the *higheſt*, or *empyrean* heaven; the *etherial*, or *ſtarry* heaven; the *planetary* heaven, &c.

HEAVEN, among *Divines*, called alſo the *empyrean* heaven, is the abode of God, and bleſſed ſpirits; as angels, and the ſouls of the righteous deceaſed.

In this ſenſe, *heaven* ſtands oppoſite to *hell*.

This

This is alſo frequently called in Scripture, the *kingdom of heaven*, the *heaven of heavens*, and by St. Paul the *third heaven*: ſometimes *Paradiſe*, the *New Jeruſalem*, &c.

This heaven is conceived as a place in ſome part of infinite ſpace, wherein the Deity is pleaſed to afford a nearer and more immediate view of himſelf, and a more ſenſible manifeſtation of his glory; and a more adequate perception of his attributes, than in the other parts of the univerſe, where he is likewiſe preſent.

This makes what the divines alſo call the *beatific viſion*. Authors are much divided as to the reality of ſuch *local* heaven.

The inſpired writers give us very magnificent deſcriptions of heaven, the ſtructure, apparatus, and attendance thereof; particularly Iſaiah, and St. John the Divine. Plato, in his Dial. de Anim. ſpeaks of heaven in terms that bear ſo near a reſemblance to thoſe of Scripture, that Euſebius charges him with borrowing his account thence. (De Præpar. Evangel. lib. xi. can. 37.) A late writer, whoſe imagination ſeems to have miſled his judgment, conceiving that the heat produced by the rays of the ſun is not in the rays themſelves, but in another diſtinct fluid, upon which they act, and which may be called the elementary fluid of heat, and, moreover, that this fluid is capable of being reduced to a fixed and ſolid ſtate, proceeds to conjecture, that the ſun is not a maſs of fire, according to the vulgar notion, but a glorions manſion, whoſe ſurface is covered with a vaſt variety of ſplendid objects, of different colours, ſhining and becoming viſible by their own emitted light; thence it may ſeem reaſonable to conclude, that the ſun is an habitation of happy beings, and becauſe of its connection with the earth, that it is "our heaven." This conjecture the author applies to the explication of many paſſages of ſcripture, and particularly of the Lord's prayer, in which he ſays there is a manifeſt diſtinction between "the heavens" and "heaven." The former, in which God is ſaid to reſide, (Our father, which art in "the heavens,") includes the numerous worlds in which he manifeſts his glory; the latter (thy will be done on earth as it is in "heaven,") denotes one peculiar heaven, the ſun. Thoſe who wiſh for more conjectures and criticiſms of this kind, may conſult a work, publiſhed in 1788, 4to, by Edward King, eſq., and entitled "Morſels of Criticiſm, &c." Some of the ancients alſo imagined that the habitation of good men, after the reſurrection, would be the ſun, grounding this fanciful opinion on a miſtaken interpretation of Pſ. xix. 4., which they rendered, with the LXX and Vulgate, "He has ſet his tabernacle in the ſun." Others again have thought it to be beyond the ſtarry firmament, a notion no leſs unphiloſophical and improbable than the former. Mr. Whiſton (Boyle's Lect. Append.) ſuppoſes the air to be the manſion of the bleſſed, at leaſt for the preſent; and he imagines, that Chriſt is at the top of the atmoſphere, and other ſpirits nearer to, or more remote from him, according to the degree of their moral purity, to which he conceives the ſpecific gravity of their inſeparable vehicles to be proportionable. Mr. Hallet, a writer of founder judgment, has endeavoured to prove, that they will dwell upon earth, when it ſhall be reſtored to its paradiſaical ſtate. (See Hallet on Script. vol. i. p. 191—240. vol. ii. p. 167—174.) The paſſages of ſcripture, however, on which he grounds his hypotheſis, are capable of another and very different interpretation. After all, we may obſerve, that the place of the bleſſed is a queſtion of comparatively little importance; and if we believe the deſcription of their happineſs, expreſſed often in highly figurative terms, we may cheerfully expect and purſue it, though we cannot anſwer a multitude of curious queſtions, relating to various circumſtances that pertain to it. We have reaſon to believe that heaven will be a ſocial ſtate, and that its happineſs will, in ſome meaſure, ariſe from mutual communion and converſe, and the expreſſions and exerciſes of mutual benevolence. (See Heb. xii. 22. 1 Theſſ. ii. 19, 20.)

The ancient Romans had a kind of heaven in their ſyſtem of theology, which they called *elyſium*, or the *elyſian fields*.

The Mahometan heaven, or *paradiſe*, is very groſs, agreeable to the genius of their religion.

Heaven, among *Aſtronomers*, called alſo the *ætherial* and *ſtarry heaven*, is that immenſe region wherein the ſtars, planets, and comets are diſpoſed.

This is what Moſes calls the *firmament*, ſpeaking of it as the work of the ſecond day's creation; at leaſt it is thus the word רקיע is uſually rendered by his interpreters; though ſomewhat abuſively, to countenance their own notion of the heavens being firm, or ſolid. (See Firmament.) The word, it is certain, properly ſignifies no more than *expanſe*, or *extenſion*; a term very well adapted by the prophet to the impreſſion which the heavens make on our ſenſes; whence, in other parts of ſcripture, the heaven is compared to a curtain, or a tent ſtretched out to dwell in. The LXX firſt added to this idea of expanſion, that of *firm* or *ſolid*; rendering it by στερεωμα, according to the philoſophy of thoſe times; in which they have been followed by the modern tranſlators.

The later philoſophers, as Des Cartes, Kircher, &c. have eaſily demonſtrated this heaven not to be ſolid, but fluid; but they ſtill ſuppoſe it full, or perfectly denſe, without any vacuity, and cantoned out into many vortices.

But others carry the thing much farther, and overturn not only the ſolidity, but the ſuppoſed plenitude, of the heavens. Sir Iſaac Newton has abundantly ſhewn the heavens void of almoſt all reſiſtance, and, conſequently, of almoſt all matter: this he proves from the phenomena of the celeſtial bodies; from the planets perſiſting in their motions without any ſenſible diminution of their velocity; and the comets freely paſſing in all directions towards all parts of the heavens.

Heaven, taken in this general ſenſe, for the whole expanſe between our earth and the remoteſt regions of the fixed ſtars, may be divided into two very unequal parts, according to the matter found therein; *viz.* the atmoſphere, or *aerial heaven*, poſſeſſed by air; and the *ætherial heaven*, poſſeſſed by a thin, unreſiſting medium, called *æther*.

Heaven is more particularly uſed, in *Aſtronomy*, for an orb, or circular region, of the ætherial heaven.

The ancient aſtronomers aſſumed as many different heavens as they obſerved different motions in them. Theſe they ſuppoſed all to be ſolid, as thinking they could not otherwiſe ſuſtain the bodies fixed in them; and ſpherical, that being the moſt proper form for motion.

Thus we had ſeven heavens for the ſeven planets; *viz.* the heavens of the Moon, Mercury, Venus, the Sun, Mars, Jupiter, and Saturn. The eighth was for the fixed ſtars, which they particularly called the *firmament*; which ſee.

Ptolemy adds a ninth heaven, which he called the *primum mobile*.

After him two cryſtalline heavens were added, by king Alphonſus, &c. to account for ſome irregularities in the motions of the other heavens: and laſtly, an *empyrean* heaven was drawn over the whole, for the reſidence of the Deity; which made the number twelve.

But others admitted many more heavens, according as their different views and hypotheſes required. Eudoxus ſuppoſed twenty-three, Calippus thirty, Regiomontanus thirty-

thirty-three, Ariſtotle forty-ſeven, and Fracaſtor no leſs than ſeventy.

We may add, that the aſtronomers did not much concern themſelves whether the heavens, they thus allow of, were real or not, provided they ſerved a purpoſe in accounting for any of the celeſtial motions, and agreed with the phenomena.

Among the other reveries of the rabbins, contained in the Talmud, we find it aſſerted, that there is a place where the heavens and the earth join together; that rabbi Barchana, going thither, laid his hat on the window of heaven; and that, going to take it again immediately after, it was gone, the heavens having carried it off; ſo that he muſt wait for a revolution of the orbs to bring it to its place again.

The indefatigable labours of Dr. Herſchel, in the ſervice of aſtronomy, are known to every lover of the ſcience. None of his numerous diſcoveries are worthy of greater attention than thoſe which relate to the conſtruction of the heavens. The ſubject, both theoretically and practically, has engaged his attention for many years; and a ſlight ſketch of his theory, as far as relates to the conſtruction of the milky-way, has already been given under GALAXY. We have now to inform our readers, in what manner Dr. H. applies his valuable and immenſe ſeries of obſervations to the conſtruction of the whole ſidereal ſyſtem of the heavens. Firſt, taking a theoretical view of the ſubject, he ſuppoſes numberleſs ſtars of various ſizes ſcattered over an indefinite portion of ſpace, in ſuch a manner as to be almoſt equally diſtributed throughout the whole. The laws of attraction, extending to the remoteſt regions of the fixed ſtars, will then, he conceives, very probably produce the following remarkable effects:

Formation of Nebulæ.

Form 1.—In the firſt place, ſince the ſtars are ſuppoſed to be of various ſizes, it will frequently happen, that a ſtar, being conſiderably larger than its neighbouring ones, will atttract them more than they will be attracted by others that are immediately round them; by which means they will be in time, as it were, condenſed about a centre; or, in other words, form themſelves into a cluſter of ſtars of almoſt a globular figure, more or leſs regularly ſo according to the ſize, and original diſtance of the ſurrounding ſtars.

Form 2.—The next caſe, which will alſo happen almoſt as frequently as the former, is where a few ſtars, though not ſuperior in ſize to the reſt, may happen to be rather nearer each other than the ſurrounding ones; for here alſo will be formed a prevailing attraction in the combined centre of gravity of them all, which will occaſion the neighbouring ſtars to draw together; not indeed ſo as to form a regular or globular figure, but, however, ſo as to be condenſed towards the common centre of gravity of the whole irregular cluſter. And this conſtruction admits of the utmoſt variety of ſhapes, according to the number and ſituation of the ſtars, which firſt gave riſe to the condenſation of the reſt.

Form 3.—From the compoſition and repeated conjunction of both the foregoing forms, a third may be derived, when many large ſtars, or combined ſmall ones, are ſituated in long extended, regular, or crooked rows, hooks, or branches; for they will alſo draw the ſurrounding ones, ſo as to produce figures of condenſed ſtars coarſely ſimilar to the former, which gave riſe to theſe condenſations.

Form 4.—We may likewiſe admit of ſtill more extenſive combinations, when at the ſame time that a cluſter is forming in one part of the ſpace, there may be another collecting in a different, but, perhaps, not far diſtant quarter, which may occaſion a mutual approach towards their common centre of gravity.

Form 5.—In the laſt place, as a natural conſequence of the former caſes, there will be formed great cavities or vacancies, by the retreat of the ſtars towards the various centres which attract them; ſo that upon the whole there is evidently a field of the greateſt variety for the heavenly bodies to exert themſelves in.

From this theoretical view of the heavens, which has been taken from a point not leſs diſtant in time than in ſpace, let us now retreat to our own ſtation, in one of the planets attending a ſtar in its great combination with numberleſs others; and in order to inveſtigate what will be the appearances from this contracted ſituation, let us begin with the naked eye.

The ſtars of the firſt magnitude being, in all probability, the neareſt, will furniſh us with a ſtep to begin our ſcale; ſetting out, therefore, with the diſtance of Sirius or Arcturus, for inſtance, as unity, let it be ſuppoſed, that thoſe of the ſecond magnitude are at double, and thoſe of the third at treble the diſtance, and ſo forth. It is not neceſſary critically to examine what quantity of light, or magnitude of a ſtar, entitles it to be eſtimated at ſuch or ſuch a proportional diſtance, as the common coarſe eſtimation will anſwer our preſent purpoſe as well: taking it then for granted, that a ſtar of the ſeventh magnitude is about ſeven times as far diſtant as one of the firſt, it follows, that an obſerver who is encloſed in a globular cluſter of ſtars, and not far from the centre, will never be able with the naked eye to ſee the end of it; for ſince, according to the above eſtimations, he can only extend his view to about ſeven times the diſtance of Sirius, it cannot be expected that his eyes ſhould reach the borders of a cluſter, which has, perhaps, not leſs than fifty ſtars in depth every where round him. The whole univerſe, therefore, will, to him, be compriſed in a ſet of conſtellations, richly ornamented with ſcattered ſtars of all ſizes. Or if the united brightneſs of a neighbouring cluſter of ſtars ſhould, in a remarkably clear night, reach his ſight, it will put on the appearance of a ſmall faint whitiſh nebulous cloud, not to be perceived without the greateſt attention.

Without conſidering other ſituations, let him be placed in a much extended ſtratum, or branching cluſter of millions of ſtars, ſuch as may fall under the third form of nebulæ, conſidered in a foregoing paragraph. Here alſo the heavens will not only be richly ſcattered over with brilliant conſtellations, but a ſhining zone, or milky way, will be perceived to ſurround the whole zone of the heavens, owing to the combined light of thoſe ſtars which are too ſmall, that is, too remote, to be ſeen.

The obſerver's ſight will be ſo confined, that he will imagine this ſingle collection of ſtars, of which he does not perceive even the thouſandth part, to be the whole contents of the heavens. Allowing him now the uſe of a common teleſcope, he begins to ſuſpect, that all the milkineſs of the bright path that ſurrounds the ſphere may be owing to ſtars. He perceives a few cluſters of them in various parts of the heavens, and finds alſo, that there is a kind of nebulous patches; but ſtill his views are not extended ſo far as to reach to the end of the ſtratum in which he is ſituated, ſo that he looks upon theſe patches as belonging to that ſyſtem which to him ſeems to comprehend every celeſtial object. He now increaſes his power of viſion, and applying himſelf to a cloſe obſervation, finds that the milky-way is indeed no other than a collection of very ſmall ſtars. He perceives that thoſe objects, which had been called nebulæ, are evidently nothing but cluſters of ſtars. He finds their number increaſe

creaſe upon him, and when he reſolves one nebula into ſtars he diſcovers ten others, which he cannot reſolve. He then forms the idea of immenſe ſtrata of fixed ſtars, of cluſters of ſtars, and of nebulæ; till going on with ſuch intereſting obſervations he perceives that all theſe appearances muſt naturally ariſe from the confined ſituation in which we are placed.

Confined indeed it may be called, though in no leſs a ſpace than what before appeared to be the whole region of the fixed ſtars; but which now has aſſumed the ſhape of a crookedly branched nebula; not indeed one of the leaſt, but perhaps, very far from being the moſt conſiderable of thoſe numberleſs cluſters that enter into the conſtruction of the heavens.

Dr. H. then gives a number of obſervations, which he calls gages, and arrives at this concluſion, "That we inhabit the planet of a ſtar belonging to a compound nebula of the third form;" the particular form and dimenſions of which have been deſcribed under the article GALAXY.

Dr. Herſchel, after giving a very detailed deſcription of our nebula, proceeds to give an account of the origin of nebulous ſtrata, and obſerves, that if it were poſſible to diſtinguiſh between the parts of an indefinitely extended whole, the nebula we inhabit might be ſaid to be one that has fewer marks of profound antiquity upon it than the reſt. He obſerves, that to explain this idea more clearly, it ſhould be recollected that the condenſation of cluſters of ſtars has been aſcribed to a gradual approach, and that whoever reflects on the number of ages that muſt have paſſed before ſome of the cluſters, that are to be found in his catalogue of them, could be ſo far condenſed as they are found at preſent to be, will not wonder that he ſhould aſcribe a certain air of youth and vigour to many very regularly ſcattered regions of our ſidereal ſtratum. There are, moreover, many places in it where there is the greateſt reaſon to believe, that the ſtars, if we may judge from appearances, are now drawing towards various ſecondary centres, and will, in time, ſeparate into different cluſters, ſo as to cauſe many ſubdiviſions. Hence we may ſurmiſe, that when a nebulous ſtratum conſiſts chiefly of nebulæ of the firſt and ſecond form, it probably owes its origin to what may be called the decay of a great compound nebula of the third form; and that the ſubdiviſions, which happened to it in length of time, occaſioned all the ſmall nebulæ which ſprung from it to be in a certain range, according as they were detached from the primary one. In like manner, our ſyſtem, after numbers of ages, may very poſſibly become divided, ſo as to give riſe to a ſtratum of two or three hundred nebulæ, for it would not be difficult to point out ſo many beginning or gathering cluſters in it. Dr. Herſchel remarks, that this view of the preſent ſubject throws a conſiderable light upon the appearance of that remarkable collection of many hundreds of nebulæ, which are to be ſeen in what he has called the nebulous ſtratum of Coma Berenices. It appears, from the extended and branching figure of our nebula, that there is room for the decompoſed ſmall nebulæ of a large reduced former great one, to approach nearer to us in the ſides than in other parts. Nay, poſſibly there might originally be another very large joining branch, which in time becomes ſeparated by the condenſation of the ſtars; and this may be the reaſon, he obſerves, of the little remaining breadth of our ſyſtem in that very place; for the nebulæ of the ſtratum of the Coma are the brighteſt and moſt crowded juſt oppoſite our ſituation, or in the pole of our ſyſtem.

As ſoon as this idea was ſuggeſted, Dr. Herſchel tried alſo the oppoſite pole, where accordingly he met with a great number of nebulæ, though under a much more ſcattered form.

Dr. Herſchel ſuſpects, that parts of our ſyſtem have already ſuſtained greater ravages of time than others, if this expreſſion may be allowed; for inſtance, he found, in the body of the Scorpion an opening or hole, which he thinks is probably owing to this cauſe. This opening is at leaſt four degrees broad, but its height is not yet aſcertained. It is remarkable that the 80 *nebuleuſe ſans etoiles* of the *Connoiſſance des temps*, which is one of the richeſt and moſt compreſſed cluſters of ſmall ſtars, is ſituated juſt on the weſtern border of it, and would almoſt authorize a ſuſpicion, that the ſtars of which it is compoſed were collected from that place, and had left the vacancy. What adds not a little to the probability of this ſurmiſe is, that the ſame phenomenon is once more repeated with the fourth cluſter of ſtars of the *Connoiſſance des temps*; which is alſo on the weſtern border of another vacancy, and has moreover a ſmall, miniature cluſter, or eaſily reſolvable nebula, of about $2\frac{1}{2}$ minutes in diameter, north following it at no very great diſtance.

Dr. Herſchel obſerves, that there is a remarkable purity or clearneſs in the heavens when we look out of our ſtratum at the ſides; that is, towards Leo, Virgo, and Coma Berenices one one ſide, and towards Cetus on the other; whereas the ground of the heavens becomes troubled as we approach towards the length or height of it. He ſays, it was a good while before he could trace the cauſe of theſe phenomena; but that ſince he has been acquainted with the ſhape of our ſyſtem, he thinks it plain that theſe troubled appearances, when we approach the ſides, are eaſily to be explained, by aſcribing them to ſome of the diſtant ſtraggling ſtars that yield hardly light enough to be diſtinguiſhed. And this, he ſays, he has often experienced to be actually the cauſe, by examining theſe troubled ſpots for a long while together, when at laſt he generally perceived the ſtars which occaſioned them. But in looking towards the poles of our ſyſtem, where the viſual ray does not graze along the ſides, the ſtraggling ſtars will of courſe be very few in number, and therefore the ground of the heavens will aſſume that purity which is always obſerved to take place in thoſe regions.

We are uſed to call the appearance of the heavens, where it is ſurrounded with a bright zone, the milky-way; there are other remarkable nebulæ which cannot well be leſs, but are probably much larger than our own ſyſtem, and being alſo extended, the inhabitants of the planets that attend the ſtars which compoſe them, muſt likewiſe perceive the ſame phenomenon; for which reaſon they may alſo be called milky-ways by way of diſtinction.

Dr. Herſchel's opinion of their age is grounded on the following obſervations. There are many round nebulæ of the firſt form, of about five or ſix minutes in diameter, the ſtars of which he can ſee very diſtinctly, and on comparing them with the viſual ray, calculated from ſome of his long gages, he ſuppoſes by the appearance of the ſmall ſtars in thoſe gages, that the centres of theſe round nebulæ may be 600 times the diſtance of Sirius from us.

In eſtimating the diſtance of ſuch cluſters, Dr. Herſchel conſulted rather the comparatively apparent ſize of the ſtars, than their mutual diſtance; for the condenſation in theſe cluſters, being probably much greater than in our own ſyſtem, if we were to overlook this circumſtance and calculate by their apparent compreſſion, where in about ſix minutes diameter there are perhaps ten or more ſtars in the line of meaſures, we ſhould find that on the ſuppoſition of an equal ſcattering of the ſtars throughout all nebulæ, the diſtance of the centre of ſuch a cluſter from us could not be leſs

than 6000 times the diſtance of Sirius. And perhaps in putting it at 600 only, it is conſiderably under-rated. Dr. Herſchel thinks, that if this ſhould be the caſe, it will ſtrengthen his opinion. But to proceed,

Some of theſe round nebulæ have others near them, perfectly ſimilar in form, colour, and the diſtribution of ſtars, but of only half the diameter; and the ſtars in them ſeem to be doubly crowded, and at only about half the diſtance from each other; they are, indeed, ſo ſmall as not to be viſible without the utmoſt attention. Theſe miniature nebulæ are ſuppoſed to be at double the diſtance of the firſt. An inſtance equally remarkable and inſtructive, is a caſe where, in the neighbourhood of two ſuch nebulæ as have been mentioned, a third is met with, ſimilar, reſolvable, but much ſmaller and fainter. The ſtars of it are no longer to be perceived, but a reſemblance of colour with the former two, and its diminiſhed ſize and light, may well permit us to place it at full twice the diſtance of the ſecond, or about four or five times that of the firſt. And yet, the nebuloſity is not of the milky kind, nor is it difficult to reſolve if colourleſs. Now in a few of the extended nebulæ, the light changes gradually, ſo as from the reſolvable to approach to the milky kind; which appears to be an indication that the milky light of the nebulæ is owing to their much greater diſtance. A nebula, therefore, whoſe light is perfectly milky, cannot well be ſuppoſed to be at leſs than ſix or eight thouſand times the diſtance of Sirius, and though the numbers here aſſumed are not to be taken otherwiſe than as very coarſe, yet an extended nebula, which in a very oblique direction, where it is probably ſhortened by one half, two-thirds or three-fourths of its length, ſubtends a degree or more in diameter, cannot be otherwiſe than of a wonderful magnitude, and may well exceed our milky-way in grandeur.

Dr. Herſchel enumerates ſeveral of this kind of nebulæ, an account of which, as well as a table of nebulæ, will be given under the article Nebulæ.

From about the year 1784, when the firſt communications were made on this ſubject to the Royal Society, Dr. Herſchel has continually added to our ſtock of information on this intereſting ſubject. In the year 1802, he gave a more minute claſſification of the celeſtial bodies, which compoſe the ſidereal ſyſtem; of which the following abridged account is given by Dr. Young, in the appendix to his lectures on Natural Philoſophy.

Dr. Herſchel takes a very enlarged view of the ſidereal bodies compoſing the univerſe, as far as he can conjecture from their nature, and enumerates a great diverſity of parts that enter into the conſtruction of the heavens, reſerving a more complete diſcuſſion of each to a future time.

The firſt ſpecies are inſulated ſtars; as ſuch, the author conſiders our ſun, and all the brighter ſtars which he ſuppoſes nearly out of the reach of mutual gravitation; for ſtating the annual parallax of Sirius at 1″, he calculates that Sirius and the ſun, if left alone, would be 38 millions of years in falling together, and that the action of the ſtars of the milky-way, as well as others, would tend to protract this time much more.

Dr. Herſchel conjectures that the inſulated ſtars alone are ſurrounded by planets. The next are binary ſidereal ſyſtems, or double ſtars; from the great number of theſe which are viſible, in different parts of the heavens, and the frequent apparent equality of the two ſtars, Dr. Herſchel calculates the very great improbability that they ſhould be at diſtances from each other at all comparable to thoſe of the inſulated ſtars. Hence he infers that they muſt be ſubjected to mutual gravitation, and can only preſerve their relative diſtances by a periodical revolution round a common centre.

In confirmation of this inference he promiſes ſoon to communicate a ſeries of obſervations made on double ſtars, ſhewing that many of them have actually changed their ſituation in a progreſſive courſe, the motion of ſome being direct, and of others retrograde. The proper motion of our ſun does not appear to be of this kind, but rather to be the effect of ſome perturbations in the neighbouring ſyſtems.

The ſame theory is next applied to triple, quadruple, and multiple ſyſtems of ſtars, and particular hypothetical caſes are explained by diagrams. Some ſuch caſes, Dr. Herſchel is fully perſuaded, have a real exiſtence in nature. The fourth ſpecies conſiſts of cluſtering ſtars and of the milky way. The ſtars thus diſpoſed conſtitute maſſes which appear brighter in the middle, and fainter towards the extremities, being perhaps collected in a ſpherical form. Groups of ſtars the author diſtinguiſhes from theſe by a want of apparent condenſation about a centre of attraction; and cluſters of ſtars by a much more complete compreſſion near ſuch a centre, ſo as to exhibit a mottled luſtre almoſt reſembling a nucleus. The eighth ſpecies conſiſts of nebulæ, which probably differ from the three laſt ſpecies only in being more remote; ſome of them, Dr. Herſchel calculated, are at ſo great a diſtance, that the rays of light muſt have been nearly two millions of years in travelling from them to our ſyſtem. The ſtellar nebulæ, or ſtars with burs, form a diſtinct ſpecies. A milky nebuloſity is next mentioned, which may, in ſome caſes, reſemble other nebulæ, but, in others, appears to be diffuſed almoſt like a fluid. The author is not inclined to conſider it as either reſembling the light of the ſun, or of a phoſphoreſcent nature. The tenth ſpecies is denominated nebulous ſtars. Theſe are ſtars ſurrounded with a nebuloſity like an atmoſphere, of which the magnitude muſt be amazingly great; for the apparent diameter of one of them deſcribed in the catalogue was 3′. The planetary nebulæ are diſtinguiſhed by their equable brightneſs and circular form, while their light is ſtill too faint to be produced by a ſingle luminary of great dimenſions. When they have bright central points, Dr. Herſchel conſiders them as forming a twelfth ſpecies, and ſuppoſes them to be allied to the nebulous ſtars, which might approach to their nature if their luminous atmoſpheres were very much condenſed round the nucleus. For a more minute account of theſe various bodies, ſee Double Star, Nebula, &c. &c.

HEAVER, in *Sea Language*, is a name given by ſeamen to a wooden ſtaff, which they employ as a lever on many occaſions; particularly in ſetting up the top-maſt ſhrouds, frapping the top-maſts, ſtropping the larger blocks, ſeizing the ſtanding rigging, &c.

HEAVINESS. See Gravity.

For the laws of the deſcent of heavy bodies, ſee Descent.

Heavy bodies do not tend preciſely to the very centre of the earth, except at the poles, and the equator, on account of the ſpheroidal figure of the earth. Their direction is every where perpendicular to the ſurface of the ſpheroid.

HEAULME, or Heaume, in *Heraldry*, a helmet, or head-piece.

HEAVY, in the *Manege*. A horſe is ſaid to reſt heavy upon the hand, who, through the ſoftneſs of his neck, the weakneſs of his back, the weight of his fore-quarters, or through wearineſs, throws himſelf upon the bridle; but without making any reſiſtance, or any effort to force the horſeman's hand. This fault is remedied, and the horſe made light upon the hand, by ſtopping, and making him go back frequently, if it proceeds only from lazineſs and ſtiffneſs; but if cauſed by any defect in the back, there is no remedy for it.

HEB, or EBB, in *Mining*, ſignifies ſhallow, as a heb pit means a ſhallow pit.

HEBBING-WEARS, in our *Statutes*, is uſed for weirs or engines made or laid at ebbing water, 23 Hen. VIII. cap. 5.

HEBDEN, JOHN, in *Biography*, a native of Yorkſhire, well known in London, in the middle of the laſt century, as a performer on the baſſoon and violoncello of the ſecond claſs. He was more a uſeful than an ornamental player on both theſe inſtruments. At Vauxhall he was ſecond on the baſſoon, where Miller was the firſt; and at Drury Lane, where Cervetto was firſt violoncello, Hebden was ſecond; yet he often played concertos on the baſſoon at benefit concerts with conſiderable applauſe.

He was totally ignorant of compoſition; and, getting young and obſcure ſtudents in counterpoint, to ſtring together a cento of muſical phraſes, from different authors, in the ſame key and meaſure for each movement, no individual had a right to claim the whole piece, in its totality.

HEBDOMADARY, HEBDOMADARIUS, or HEBDOMADIUS, a member of a chapter or convent, whoſe week it is to officiate in the choir, to rehearſe the anthems and prayers, and to perform the uſual functions which the ſuperiors perform at ſolemn feaſts, and other extraordinary occaſions.

The word is formed of the Greek ἑβδομας, which ſignifies the number *ſeven*; of επτα, *ſeven*.

The hebdomadary generally collates to the benefices which become vacant during his week; though it is uſually looked on as an abuſe.

In cathedrals the hebdomadary was a canon or prebendary who had the peculiar care of the choir, and the inſpection of the officers of his week.

In monaſteries the hebdomadary is he who waits at table for a week, or other ſtated period; directs and aſſiſts the cook, &c.

In church-antiquity we meet with accounts of nine different ſorts of hebdomadaries, *viz* the *hebdomadarius cantor*, or hebdomadary cantor; *hebdomadarius chori*, hebdomadary of the choir; which two were really the ſame, *viz.* he who led or conducted the public ſervice; hebdomadary of the kitchen, *hebdomadarius coquinæ*; hebdomadary of the defunct, or the dead, *hebdomadarius defunctorum*, he who took care of the office and ſervice of the dead; *hebdomadarius invitatorii*, he who ſung the invitatory; *hebdomadarius lector ad menſam*, he who read at meal time; *hebdomadarius majoris miſſæ*, he who read maſs; *hebdomadarius pſalterii*, who probably was the ſame with the *hebdomadarius chori*; and *hebdomadarius ſacri altaris*, who might be the ſame with the hebdomadary of the high maſs.

HEBDOME, Ἑβδομη, among the Athenians, a feſtival or holy day kept always on the ſeventh day of the moon in honour of Apollo; that being ſuppoſed to have been his birth-day.

HEBE, in *Ancient Mythology*, a goddeſs, the daughter of Jupiter and Juno, the idea of whom, among the Romans, ſeems to have been much the ſame with that of eternal youth, or an immortality of bliſs; agreeably to which, ſhe is repreſented on a gem, in the great duke's collection at Florence, with a young airy look, and drinking out of a little bowl; or, according to Milton's expreſſion, "Quaffing immortality and joy." Hebe is ſaid to have been married to Hercules after his deification.

HEBE, in *Botany*, a name given by Commerſon, and adopted by Juſſieu, to the *Veronica decuſſata* of Aiton's Hortus Kewenſis, ed. 2. v. 1. 31. Curt. Mag. t. 242, which, with ſome other ſpecies that have ovate capſules and are rather of a ſhrubby habit, have been ſuſpected to conſtitute a diſtinct genus, but, we believe, without ſufficient grounds. Such are, *V. parviflora*, *macrocarpa*, *ſalicifolia*, and *cataractæ* of Vahl's Enumeratio Plantarum, v. 1. 66, 67.

HEBENSTREIT, JOHN ERNEST, in *Biography*, profeſſor of medicine in the univerſity of Leipſic, was born at Neuſtadt, in Germany, in the year 1703, or, as we learn from other accounts, in the preceding year (Dryander. Bibl. Banks. v. 5. 272.)—During the earlier part of his life it appears that he purſued his ſtudies at Jena, from whence he removed to Leipſic; and at this latter place he took, ſucceſſively, the degrees of maſter of arts and doctor of phyſic. Before he attained the age of 30, at the command of Frederic Auguſtus II. king of Poland and elector of Saxony, he undertook a voyage to Africa, being accompanied by Ludwig, and ſome other philoſophical friends, to aſſiſt in his reſearches, for the purpoſe of inveſtigating the natural hiſtory of that part of the world; but a complete account of this expedition has never been publiſhed. Dr. Aikin, in his General Biography, on the authority of Hirſching, informs us, that "Hebenſtreit, having explored the neighbourhood of Tripoli and Tunis, travelled through part of the deſart between theſe two towns, and examined the ruins of Carthage, but was obliged, on account of the king's death, to return rather ſuddenly in the year 1733." He brought home with him, however, many valuable curioſities of nature, which were partly preſented to the menagerie at Dreſden, and partly lodged in the king's private muſeum. Auguſtus III. following the ſteps of his father, continued to patronize the ſubject of theſe memoirs, and cauſed him to be appointed public profeſſor of medicine at Leipſic ſoon after his return from Africa. In this profeſſorſhip he remained till his death, which was occaſioned by a malignant fever that prevailed immediately after the battle of Roſbach, in the year 1757. "Hebenſtreit poſſeſſed an extenſive knowledge of philoſophy, medicine, both ancient and modern, natural hiſtory, botany, and anatomy. He had a ready talent for Latin poetry, and was well verſed in the Greek language. He was deeply ſkilled in the ſtudy of nature, and to him Leipſic is in part indebted for a valuable collection of curioſities." He zealouſly defended the ſyſtem of botany which was founded by Rivinus upon the corolla, againſt the various objections to it which were urged by Ray, Schelhammer, Rudbeck, and Dillenius. The following is a liſt of his works.

Muſeum *Richterianum*, continens foſſilia, animalia, vegetabilia marina, illuſtrata iconibus et commentariis. *Lipſiæ*, 1743, folio.

Programmata:

De organis piſcium externis. 1733.

De methodo plantarum ex fructu optimâ. 1740.

De vermibus anatomicorum adminiſtris. 1741.

De inſectorum natalibus. 1743.

Hiſtoriæ naturalis inſectorum inſtitutiones proponens. 1745.

De fœtu vegetabili. 1747.

De ordinibus gemmarum, verbis C. Plinii, ex ejus naturalis hiſtoriæ libris 37. 1747.

The following diſſertations were written and defended by graduates under the preſidency of Hebenſtreit.

De ordinibus Conchyliorum methodicâ ratione inſtituendis. Reſp. Joh. Gezaur. 1728.

De ſenſu externo facultatum in plantis judice. Reſp. Chr. Gottlieb Ludwig. 1730.

Definitiones plantarum. Reſp. Chr. Aug. Eberſbach. 1731.

Hiſtoriæ

Hiſtoriæ naturalis foſſilium caput de terris. Reſp. Jo. Ge. Lutherus. 1745.

All the above tracts were publiſhed at Leipſic, and in quarto. Haller's Bibl. Bot. Aikin's General Biography.

HEBENSTREITIA, in *Botany*, was ſo named by Linnæus in honour of profeſſor John Erneſt Hebenſtreit (ſee laſt article). Linn. Gen. 318. Schreb. 416. Willd. Sp. Pl. v. 3. 330. Mart. Mill. Dict. v. 2. (rather *Perſonatæ*.) *Viticibus affine*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, tubular, membranaceous, emarginate, opening longitudinally underneath. *Cor.* of one petal and one lip; tube cylindrical, longer than the calyx, gaping on the lower ſide half way; limb aſcending, flattiſh, four-cleft, clefts nearly equal. *Stam.* Filaments four, the upper pair inſerted into the margin of the corolla, prominent; the lower anterior pair are included and bent back to the ſides; anthers creſcent-ſhaped, compreſſed, truncated outwards. *Piſt.* Germen ſuperior, very ſmall; ſtyle thread-ſhaped, wavy, bent back through the fiſſure of the corolla; ſtigma ſimple. *Peric.* Capſule oblong, of one cell and two valves. *Seeds* two, oblong, convex, and three-furrowed on one ſide, plain on the other.

Eſſ. Ch. Calyx doubly emarginate, cloven underneath. Corolla of one, aſcending, four-cleft lip. Capſule containing two ſeeds. Stamens ſtanding in the margin of the limb of the corolla.

All the ſpecies of this curious genus are natives of the Cape of Good Hope. The two beſt known in our gardens are *Hebenſtreitia dentata*, and *aurea*, which are deſcribed below. Willdenow enumerates five others, H. *ciliata*, *integrifolia*, *erinoides*, *fruticoſa*, and *cordata*.

1. H. *dentata*. Toothed Hebenſtreitia. Linn. Sp. Pl. 878. Curt. Mag. t. 483.—"Leaves linear, acute, flat, ſlightly toothed, ſometimes entire; ſpikes of flowers ſmooth."—Not unfrequent in green-houſes, and capable of being propagated by cuttings, though with ſome difficulty; flowering from February to November. *Stem* erect, about a foot high. *Branches* ſimple, aſcending. *Leaves* alternately ſcattered, linear, ſomewhat hiſpid and dentate, ſpreading or recurved, furniſhed with little axillary tufts. *Spike* terminal, barren on the lower part, bracteas ſmooth, awl-ſhaped, imbricated, ſingle-flowered. *Corolla* white, with a yellow and red ſtripe, having the ſtamens curiouſly placed on the edge of its fiſſure. *Seeds* of a pale yellow.—Linnæus remarks that "its flowers in the morning are without ſcent; at noon they are naſeouſly fœtid; in the evening highly fragrant, like the oriental hyacinth."

2. H. *aurea*. Golden-flowered Hebenſtreitia. Andr. Bot. Repoſ. t. 252.—"Leaves ſomewhat cylindrical, obtuſe, entire; ſpikes of flowers ſmooth."—Introduced in 1796 by Meſſrs. Lee and Kennedy. It may be increaſed by cuttings, and if theſe are taken off in May, they will become flowering plants in September. *Stems* ſmooth and branched. *Leaves* linear, entire, ſomewhat whorled. *Spike* formed of beautiful golden-coloured flowers, variegated with deep orange.—The flowers become extremely fragrant in an evening.

HEBER, or Eber, in *Scripture Biography*, the father of Peleg and the ſon of Salah, who was the grandſon of Shem, one of Noah's ſons, was born A. M. 1723, B.C. 2281. From him ſome have ſuppoſed that Abraham and his deſcendants derived the appellation of Hebrews. But others have ſuggeſted, with greater probability, that Abraham and his family were thus called, becauſe they came from the other ſide of the Euphrates into Canaan; Heber (עבר) ſignifying in the Hebrew language "one that paſſes," or a "paſſage," *i. e.* of the river Euphrates. Heber is not particularly extolled in ſcripture, ſo that a whole nation ſhould be diſtinguiſhed by his name. Upon the whole, the moſt probable opinion concerning the origin of the appellation Hebrew, applied to Abraham and his poſterity, is that already ſtated: that it is derived from the prepoſition עבר, *trans*; from whence thoſe that lived *beyond*, or to the eaſt of the river Euphrates, were called by the Canaanites and others who lived in the weſt, עברים, *Enebbrim*. Le Clerc takes בני עבר, *beni gnebber*, (Gen. x. 21.) to be a Hebraiſm, denoting the inhabitants of the country beyond the Euphrates. Hence the ſenſe of the text is, that all this eaſtern part of the world was peopled by Shem's poſterity. Thus the LXX, as we have already ſaid, underſtood this word. Thus, alſo, among the ancients, Theodoret and Jerom, as well as ſome others; and among the moderns, Grotius and Le Clerc underſtand the word "Hebrew." According to this opinion, Hebrew ſignifies much the ſame as foreigner among us, or one that comes from beyond ſea. Such were Abraham and his family among the Canaanites; and his poſterity, learning and uſing the language of the country, ſtill retained the appellation originally given them, even when they became poſſeſſors and ſettled inhabitants. Beſides, Abraham was the ſeventh in lineal generation from Heber (Gen. xi. 10, &c.); and it ſeems to be more likely that Abraham ſhould take a name that was to deſcend to his family after him from a circumſtance that applied more generally to the deſcendants of Shem, of whom it is ſaid (Gen. x. 21.) that he was "the father of all the children of Heber," *i. e.* of thoſe on the other ſide of the Euphrates. Abraham was not called an Hebrew till ten years after his arrival in the land of Canaan, on occaſion of the war with Chedorlaomer. The LXX and Aquila tranſlate "Heberi" *Perates* or *Peraites*, which ſignifies a paſſenger, or one who came from beyond the river. (Gen. xiv. 13.) הָעִבְרִי אברהם, LXX. Ἄβραμ τῷ Περάτῃ Aquila, τῷ περαίῃ. See Walton's Prolegomena.

The rabbins, indeed, pretend, that he was a man of ſingular piety, and that the primitive religion and language were preſerved by him and his family; to which they add, that Abraham and his poſterity are called Hebrews, becauſe they ſpoke the ſame language, and profeſſed and practiſed the ſame religion with that of Heber. But theſe facts are deſtitute of ſatisfactory evidence. It is not certain that Heber uſed the Hebrew language; and as to his preſerving the true religion in his family, this by no means agrees with Joſhua's ſaying, that the anceſtors of the Iſraelites, who, in old time, dwelt "on the other ſide of the flood," even Terah, "the father of Abraham, ſerved other gods." Joſh. xxiv. 2.

HEBERDEN, William, in *Biography*, an amiable and learned phyſician, was born in London in the year 1710. Having received his early education in his native city, he was entered of St. John's college, Cambridge, in 1724; and, after a reſidence of ſix years, he was elected fellow of that ſociety. From this time he devoted himſelf to the ſtudy of medicine, partly at Cambridge, and partly in the metropolis. After he had taken the degree of M.D., he ſettled at Cambridge, where he practiſed his profeſſion during ten years, and gave lectures on the materia medica annually to the ſtudents in the univerſity. While he reſided here, we believe, he printed a little tract, entitled "Ἀντιδοτάρια; An Eſſay on Mithridatium and Theriaca:" 1745; the place of publication is not mentioned in the title-page. This tract contained a hiſtory of theſe medicaments, and an expoſure of the

the abſurdity of employing ſuch a medley of diſcordant ſimples. Dr. Heberden removed to London in 1748, to the general regret of the univerſity and town of Cambridge, where his profeſſional ſkill and ſuavity of manners had obtained for him a high eſteem. He had already been elected a fellow of the College of Phyſicians, and was ſhortly after admitted into the Royal Society. He ſoon roſe to a conſiderable profeſſional reputation, and enjoyed a large ſhare of medical practice in the metropolis, which he conducted with great honour and liberality, and with a conſtant attention to the improvement of the art, at once adorning and extending the uſefulneſs of his profeſſion. To Dr. Heberden's ſuggeſtion the public is indebted for the publication of the "Medical Tranſactions of the College of Phyſicians," the firſt volume of which appeared in 1768, and two others ſubſequently in 1772 and 1785. Among the uſeful communications contained in theſe volumes, the papers of Dr. Heberden himſelf are moſt prominent in number and value. His account of a fatal diſorder of the cheſt, which he denominated *Angina pectoris*, firſt called the attention of phyſicians to it, as an idiopathic diſeaſe: and the numerous caſes of it, which have ſince been promulgated, evince its frequency and importance. In this work, alſo, Dr. Heberden firſt gave an accurate deſcription of the chicken-pox, pointing out its diagnoſtic ſymptoms with preciſion, chiefly with a view to prevent the very eaſy miſtake of confounding it with a mild ſmall-pox. Dr. Heberden communicated ſome other papers to the Royal Society, which were printed in its Tranſactions.

During a period of thirty years Dr. Heberden continued to enjoy the confidence of the public, and to reap conſiderable emolument from the exerciſe of his profeſſion. As his years advanced, he began to relax from the fatigues of practice in the ſummer ſeaſon, and paſſed a few months in a country retreat at Windſor. In the year 1782 he terminated his profeſſional ſervices, by compiling the records of his long experience into a volume of Commentaries. He had ever accuſtomed himſelf to take notes in the ſick chamber of all the peculiarities of diſeaſe; and, at the end of each month, arranged theſe deſultory obſervations under their proper heads;—a practice not leſs calculated to form the mind to accuracy of obſervation, than to lay up a ſtore of practical knowledge. From theſe arranged collections, when he had reached his ſeventy-ſecond year, he compoſed his volume, which was written in elegant Latin, and laid up in manuſcript, not to be given to the public till after his death;—an injunction probably proceeding from an averſion to being involved in any controverſial diſcuſſions. For ſeveral years afterwards, he enjoyed the rewards of a virtuous and temperate life in a deſirable old age, cheered by domeſtic enjoyments, and ſcientific and literary purſuits. He ſunk calmly under the load of years in 1801, after completing the ninetieth year of his age, and was buried in the pariſh church of Windſor.

In the year 1802, the work above alluded to was publiſhed by his ſon, Dr. William Heberden, junior, under the title of "Gulielmi Heberden Commentarii de Morborum Hiſtoria et Curatione," in octavo; an Engliſh copy of it, from the author's own MS., appeared at the ſame time. Theſe faithful records of experience are related with perfect candour, and without any admixture of hypotheſis; and if the powers of medicine are eſtimated moderately, and the ſtock of facts but little augmented, the experienced practitioner will not deem them the more diſtant from truth, or conſider the various comparative reſults of different modes of treatment, ſo well eſtabliſhed in many inſtances, as leſs valuable to the profeſſion.

Few men have maintained a more uniformly eſtimable character through life than Dr. Heberden. Mild, candid, and modeſt in his diſpoſition, his conduct was marked by the ſtricteſt integrity, and by a ſuperiority to all unworthy acts of advancement. He was a munificent patron of letters and ſcience, without diſtinction of ſect or party. His converſation was diſtinguiſhed by cheerfulneſs, liberality, and good ſenſe; and his company was made up of the moſt learned men of the age in which he lived. See the life prefixed to his Commentaries. Gen. Biog.

HEBERMAN, in *Ancient Law Books*, a poacher, or a fiſherman below London bridge; thus called, becauſe he commonly fiſhes at ebb-water.

HEBERTHEFT, in *Ancient Cuſtoms*, a privilege of having the goods of a thief, and the trial of him, within a particular diſtrict.

HEBRAICA Concha, in *Natural Hiſtory*, a name given by authors to a very beautiful ſea-ſhell of the voluta kind, from a number of black marks, which ſeem to reſemble the Hebrew characters. See Conchology.

HEBRAISM, an idiotiſm, or manner of ſpeaking peculiar to the Hebrew tongue. For the probable origin of the appellation, ſee Heber.

There is no underſtanding even the verſions of the Old Teſtament, without ſome acquaintance with the Hebrew; they are ſo full of Hebraiſms.

We have abundance of Hebraiſms borrowed from ſcripture, and naturalized in our own language: as *Son of perdition; to ſleep in the Lord*, &c.

Maſclef has given an ample collection of the Hebraiſms that occur in the Sacred Writings, in the firſt volume of his excellent Hebrew Grammar; which the biblical critic will find it not only uſeful, but abſolutely neceſſary to conſult, in order to underſtand the phraſeology both of the Old and New Teſtaments. Theſe Hebraiſms conſiſt partly of ſingle words, which are of three ſorts, ſuch as are properly of Hebrew extract, as Meſſias, Satanas, &c. with a Greek termination, and σαββατον, Αβαδδων, &c. which retain the Hebrew termination; ſuch as are of a Greek extract, but uſed in a different ſenſe from that which they have in other authors, and in a manner conformable to the Hebrew, as βιβλος for a catalogue, like ספר, *Sipher*, (Matt. i. 1.: ρημα, which in Greek ſignifies a word, but in the New Teſtament ſometimes a thing, like דבר, *dabbar*, (Luke, i. 37.); and ſome words that are newly-coined, by which Hebrew words are tranſlated, as αναθεματιζω for חרם, *charam*, (Mark, xiv. 71.) Again, Hebraiſms are found in phraſes; either ſuch as have not been uſed by other Greek authors, as ſeeing of life and death for living and dying (Heb. xi. 5.); or ſuch as have not been uſed by other Greek writers in the ſame ſenſe as in the New Teſtament, as to hear the voice of a perſon ſignifies to obey (John, xviii. 37.), parallel with Gen. iii. 17. There are alſo pleonaſms in the New Teſtament, ſuch as do not occur in the Greek authors, as John, vi. 5. compared with Gen. xxii. 4., Acts, iv. 34. compared with Judg. ix. 7., &c. There are alſo conſtructions in the New Teſtament, which are ſaid to be Hebraiſms; as the feminine gender for the neuter, Matt. xxi. 42, Pſalm cxviii. 23;—a noun repeated twice, to expreſs a diſtribution into ſeveral parts, Mark, vi. 39, 40. compared with Gen. xxxii. 16., Mark, vi. 7. compared with Gen. vii. 2;—the ſuperlative degree expreſſed by the addition of Θεου, Acts, vii. 20. compared with Jonah, iii. 3.—Some verbs are ſaid to be uſed with different conſtructions from what they are in other Greek authors, as προσκυνεω, with a dative caſe, Matt. viii. 2., John, ix. 38.; ειναι εις τι for ειναι τι is alſo ſaid to be an Hebraiſm, Matt.

xix.

xix. 5.—Hebrew figures occur in the New Teſtament; as enallage of the caſe, perſon, number, and gender, Rev. ii. 26., iii. 12; Luke, i. 55, &c. Matt. xxiii. 37., Matt. xii. 1. Col. ii. 19.—Pleonaſms are ſaid to be borrowed from the Hebrew, Acts, xv. 17. compared with Joſh. i. 3.—Ellipſis is a common figure in the New Teſtament, after the manner of the Hebrew, Matt. xxiii. 34. compared with 2 Kings x. 23. For other inſtances, ſee Jennings's Jewiſh Antiq. vol. i. The beſt treatiſe, ſays the learned Marſh, in his Notes to the Tranſlation of Michaelis's Introduction on the Hebraiſms of the New Teſtament, is Johannis Vorſtii de Hebraiſmis, Novi Teſt. Commentarius ad Fiſcher, Lipſiæ, 1778. See *Language of the New* TESTAMENT.

HEBREW *of the* HEBREWS, an appellation which the apoſtle Paul applies to himſelf (Phil. iii. 5.), concerning the meaning of which there has been ſome difference of opinion. Godwin, in his "Moſes and Aaron," underſtands by this expreſſion, an Hebrew both by father's and mother's ſide. But if it meant no more than this, there was little occaſion for the apoſtle's uſing it, immediately after having declared, that he was "of the ſtock of Iſrael, and the tribe of Benjamin," which, on Godwin's ſuppoſition, is the ſame as an Hebrew of the Hebrews; for the Jews were not allowed to marry out of their own nation. Beſides, it is not likely that St. Paul would have mentioned it as a diſtinguiſhing privilege and honour, that his parents were not proſelytes. It is more probable that a Hebrew of the Hebrews ſignifies a Hebrew both by nation and language, which many of Abraham's poſterity, in thoſe days, were not; or one of the Hebrew Jews who performed their public worſhip in the Hebrew tongue; for ſuch were reckoned more honourable than the Helleniſtic Jews. See HELLENISTS.

HEBREW, ſomething relating to the people of the Jews, *i. e.* the twelve tribes, deſcending from the twelve patriarchs, ſons of Jacob. See JEWS.

HEBREW *Accents* are very numerous, ſome reckoning 40 and others reducing them to 30, and even a leſs number. Of theſe there are ſeveral, whoſe uſe is not well aſcertained, notwithſtanding all the inquiries of the learned in reference to this ſubject. In general three things are known concerning them, that they ſerve to diſtinguiſh the ſentences, and the number of ſentences, like the points and commas, &c. in the Engliſh; 2. To determine the quantity of the ſyllables; and, 3. To mark the tone with which they are to be ſpoken or ſung. It is no wonder then, that there ſhould be more accents in Hebrew than in other languages; as they perform three diſtinct offices, which, in other languages, are called by different names. See ACCENT.

HEBREW *Bible*. See BIBLE.

HEBREW *Character*. There are two kinds of Hebrew characters: the *ancient*, called alſo the *ſquare*; and the *modern*, or *rabbinical* characters. The *ſquare* Hebrew take its denomination from the figure of its characters, which ſtand more ſquare, and have their angles more exact and preciſe than the other.

This character is uſed in the text of holy ſcripture, and the other principal and moſt important writings. When both this and the rabbinical character are uſed in the ſame work, the former is for the text, or the fundamental part; and the latter for the acceſſory part; as the gloſs, notes, commentaries, &c.

The beſt and moſt beautiful characters of this kind, are thoſe copied from the characters of the Spaniſh manuſcripts; next, thoſe from the Italian manuſcripts; then thoſe from the French; and laſtly, thoſe of the Germans, whoſe characters are much the ſame, with reſpect to the other genuine

ſquare Hebrew characters, that the Gothic, or Dutch characters are, with reſpect to the Roman.

Several authors contend, that the *ſquare* character is not the real ancient Hebrew character, written from the beginning of the language to the time of the Babyloniſh captivity; but that it is the Aſſyrian, or Chaldee character, which the Jews aſſumed, and accuſtomed themſelves to, during the captivity, and retained afterwards. They ſay that the Jews, during the captivity, had quite diſuſed their ancient character; ſo that Ezra found it neceſſary to have the ſacred books tranſcribed into the Chaldean ſquare character. Theſe authors add, that what we call the *Samaritan* character, is the genuine ancient Hebrew.

Of this opinion are Scaliger, Bochart, Caſaubon, Voſſius, Grotius, Walton, Capellus, &c. and among the ancients, Jerom and Euſebius. Joſeph Scaliger, in his notes upon Euſebius's "Chronicon," thinks it ſo evident, that the ſacred books were originally written in the Samaritan character, at leaſt thoſe of them that were written before the captivity, that it is "luce clarius," and with a politeneſs not very decorous, though too common, in ſuch a great critic, he calls thoſe of a contrary opinion, "ſemi-docti, ſemi-theologi, ſemi-homines, and aſini." This critic, and others of the ſame opinion, allege, that the Samaritan was the ancient Phœnician character, and conſtantly uſed by the Jews till the Babylonian captivity; when, learning the Chaldee character from the Babylonians, they preferred it to their own on account of its far ſuperior beauty. So that by the time they returned from the captivity they had, in a manner, quite diſuſed their ancient characters; for which reaſon, Ezra found it requiſite to have the ſacred books tranſcribed into the Chaldean ſquare character, and from that time the old character hath been retained only by the Samaritans. On this ſide it is urged, that the preſent characters are called Aſſyrian by the ancient Jewiſh writers of the Talmud, and, therefore, muſt have been brought from Aſſyria; but to this argument it is replied, that there were two ſorts of characters anciently in uſe, *viz.* the ſacred, or preſent ſquare character, and the profane or civil, which we call Samaritan; and that the ſacred is called Aſſyrian, becauſe it firſt began in Aſſyria to come into common uſe. It is farther alleged, that the Chaldee letters, which the Jews now uſe, were unknown to the ancient Jews before the captivity, from Dan. i. 4. Moreover, it is inferred from 2 Kings, xvii. 28. whence we learn that a Jewiſh prieſt was ſent to teach the Samaritans the worſhip of Jehovah; on which occaſion he muſt have taught them the law; and yet no mention occurs of his teaching them the language or character; that the law was then written in the character which the Samaritans uſed. Beſides, it is argued in favour of the Samaritan character from the authority of Jerom, who obſerves, on occaſion of the prophet Ezekiel's being ordered "to ſet a mark," in the Hebrew ת, *tau*, "upon the forehead of the men that ſigh and cry for the abomination done in the midſt of Jeruſalem," (Ezek. ix. 4.); that this mark was the ſign of the croſs, there being a reſemblance of that figure in the *tau* of the ancient alphabet; which, ſays he, is what the Samaritans now uſe. If ſo, the form of this letter muſt have been, as ſome aſſert it was, different in his time from what it is at preſent, in which the reſemblance is very ſmall. But the chief argument is taken from ſome ancient Jewiſh ſhekels, with a legend on one ſide. "The ſhekel of Iſrael;" and on the other "Jeruſalem the holy," both in Samaritan characters. Theſe ſhekels, it is ſaid, muſt have been coined before the diviſion of the two kingdoms of Judah and Iſrael, or, at leaſt before the Aſſyrian captivity, becauſe

the

the Samaritans never afterwards reckoned Jeruſalem holy. This argument ſeems, indeed, to be demonſtrative. Nevertheleſs, conſidering the many notorious impoſitions with reſpect to coins and medals, we ſhould be well aſſured of the genuineneſs of theſe ſhekels, before we are abſolutely determined by them. On the other ſide, or for the primitive antiquity of the ſquare character, are the two Buxtorfs, Leuſden, Calovius, Hottinger, Spanheim, Lightfoot, &c. They urge, from Matthew, v. 18. that *jod* is really the leaſt of the conſonants in the preſent Hebrew, whereas it is one of the largeſt characters in the Samaritan alphabet. Schickard calls this "argumentum palmarium;" but Walton replies, that if our Saviour here ſpeaks of the leaſt letter of the alphabet, which, however, he does not admit, we can only infer that the preſent Chaldee character was uſed in our Saviour's time, which is not denied by thoſe who maintain the Samaritan to be the original. The advocates in favour of the Samaritan character alſo allege the following paſſage of Iſaiah, "of the increaſe, לְמַרְבֵּה, *lemarbeh*, of his government and peace, there ſhall be no end, &c." (Iſa. ix. 7.), where the word לְמַרְבֵּה, *lemarbeh*, hath a mem clauſum in the middle of it, of which there are only two inſtances. This, it is imagined, contains a myſtery, and ſignifies that Chriſt ſhould come "ex utero clauſo." But this cannot be expreſſed in the Samaritan character, becauſe it has no mem clauſum. The prophecy of Iſaiah, therefore, it is ſaid, was originally written in the preſent character. It is anſwered by Walton, &c. that it is only gratis dictum, there is any myſtery in this letter; and the eaſieſt way of accounting for it is to attribute it to the careleſſneſs of ſome tranſcriber. They alſo allege, that the Jews were too obſtinate and ſuperſtitious to allow their ſacred character to be altered; but if this was done under the direction and authority of Ezra, the argument will be much invalidated. Farther they ſay, that Ezra could not alter the ancient character, becauſe it was impoſſible to make the alterations in all their copies. This argument, however, is contradicted by fact; ſince the old Engliſh black letter is actually changed for the Roman. They ſay, likewiſe, that Ezra was not diſpoſed to profane the ſacred writings with a heathen character; but this ſuppoſes that Ezra was ſo ſuperſtitious as to imagine, that there was ſome peculiar ſanctity in the ſhape of the letters. Moreover, the advocates for this opinion appeal to ancient coins found in Judea, with a legend in the Chaldee or Aſſyrian character. But the genuineneſs of theſe coins is much ſuſpected.

The learned Jeſuit Souciet maintains, with great addreſs, that the ancient Hebrew character is that found on the medals of Simon, and others, commonly called *Samaritan medals*; but which, he aſſerts, were really Hebrew medals, ſtruck by the Jews, and not the Samaritans.

Buxtorf endeavours to reconcile theſe two opinions, by producing a variety of paſſages from the rabbies to prove, that both theſe characters were anciently uſed; the preſent ſquare character being that in which the tables of the law, and the copy depoſited in the ark were written; and the other character being uſed in the copies of the law, which were written for private and common uſe, and in civil affairs in general; and that after the captivity, Ezra enjoined the former to be uſed by the Jews on all occaſions, leaving the latter to the Samaritans and apoſtates. But it can hardly be allowed by any who conſider the difference between the Chaldee and Samaritan characters, with reſpect to convenience and beauty, that they were ever uſed at the ſame time. After all, it is of no great moment which of theſe, or whether either of them, were the original characters; ſince it appears, that no change of the words has ariſen from the manner of writing them, becauſe the Samaritan and Jewiſh Pentateuch almoſt always agree after ſo many ages. It is moſt probable that the form of theſe characters has varied in different periods; this appears from the teſtimony of Montfaucon, in his Hexapla Origenis, vol. i. p. 22. &c. and is implied in Dr. Kennicott's making the characters, in which manuſcripts are written, one teſt of their age. See Jenning's Ant. vol. ii. p. 336, and the authors there cited. Kennicott's Diſſ. on the Hebrew Text, vols. i. and ii.

HEBREW *Character, modern*, or *rabbinical*, is a good neat character, formed of the ſquare Hebrew, by rounding it, and retrenching moſt of the angles or corners of the letters, to make it the more eaſy and flowing. The letters uſed by the Germans are very different from the rabbinical character uſed every where elſe, though all formed alike from the ſquare character; but the German in a more ſlovenly manner than the reſt.

The rabbins frequently make uſe either of their own, or the ſquare Hebrew character, to write the modern languages in. There are even books in the vulgar tongues, printed in Hebrew characters; inſtances whereof are ſeen in the French king's library.

HEBREW *Language*, called alſo abſolutely Hebrew, is the language ſpoke by the HEBREWS, (which ſee,) who were ſo called, as ſome have ſaid, from Heber, the ſon of Shem, wherein all the books of the Old Teſtament are written; whence it is alſo called the *holy* or *ſacred language*. It is ſaid to have been preſerved in the midſt of the confuſion at Babel, in the family of Heber, or Eber, who, as it is alleged, was not concerned in the building of Babel, and, conſequently, did not ſhare in the puniſhment inflicted on the actual aggreſſors. The Jews, in general, have been of opinion, that the Hebrew was the language of Heber's family, from whom Abraham ſprung. On the other hand, it has been maintained, that Heber's family, in the fourth generation after the diſperſion, lived in Chaldea, where Abraham was born (Gen. xi. 27, 28.), and that there is no reaſon to think they uſed a different language from their neighbours around them. It appears, moreover, that the Chaldee, and not the Hebrew, was the language of Abraham's country, and of his kindred (Gen. xxiv. 4. Gen. xxxi. 46, 47.); and it is probable, that Abraham's native language was Chaldee, and that the Hebrew was the language of the Canaanites, which Abraham and his poſterity learnt by travelling among them. For proof of this point we refer to Le Clerc's Prolegomena, 1. in Pentateuch de Ling. Heb. J. Scalig. Epiſt. 242 & 363. Walt. Proleg. ii. § 13—19. Selden, c. 2. Proleg. de Diis Syris.

There is no piece in all antiquity, written in pure Hebrew, beſide the books of the Old Teſtament; and even ſome parts of thoſe are in *Chaldee*; which ſee.

The Hebrew, then, appears to be the moſt ancient of all the languages in the world; at leaſt it is ſo with regard to us, who know of no older. Dr. Sharpe adopts the opinion, that the Hebrew was the original language; not indeed that the Hebrew is the unvaried language of our firſt parents, but that it was the general language of men at the diſperſion; and however it might have been improved and altered from the firſt ſpeech of our firſt parents, it was the original of all the languages, or almoſt all the languages, or rather dialects, that have ſince ariſen in the world. Origin, &c. of Languages, p. 22, &c.

Other arguments have been deduced from the nature and genius of the Hebrew language, in order to prove that it was the original language, neither improved nor debaſed by foreign idioms. The words of which it is compoſed are

ſhort, and admit of very little flexion. The names of places are deſcriptive of their nature, ſituation, accidental circumſtances, &c. The compounds are few, and inartificially conjoined; and it is leſs burdened with thoſe artificial affixes, which diſtinguiſh other cognate dialects, ſuch as the Chaldean, Syrian, Arabian, Phœnician, &c. From the age of Moſes to the era of the Babyloniſh captivity, when the Hebrew language declined, and even during the age of David and Solomon, which has been reckoned its golden period, it does not ſeem to have undergone any material improvement; nor were the Jews, either from their diſpoſition or circumſtances, likely to have improved it. Like other unimproved languages, it abounds in figurative expreſſions borrowed from ſenſible objects. If we compare the Hebrew with other languages, ſuch as the Chaldæan, Syrian, Arabian, &c. which have contended with it for originality, we find theſe to have been ſo varied by ſucceſſive improvements, that on this account, independently of every other conſideration, they are not likely to have been the original language, as the moſt ancient language is, *cæteris paribus*, that which is leaſt improved. This has been particularly the caſe with reſpect to the Chaldæan, ſo that although this and the Hebrew might originally have been the ſame, the former appears now to be different in conſequence of its having been more improved. Camden, indeed, many of the fathers, and ſeveral learned writers, have aſcribed priority to the Chaldee; but, as we conceive, without ſufficient reaſon. Erpenius, indeed, in his oration for the Hebrew tongue, having conſidered the arguments for and againſt the alleged claims of theſe two languages, heſitated in deciding the queſtion.

The generality of eaſtern writers allow the preference in this reſpect to the Syriac, except the Jews, who with great ardour contend for the antiquity of the Hebrew; and with them ſeveral Chriſtian writers agree; particularly Chryſoſtom, Auſtin, Origen, and Jerom among the ancients, and among the moderns Bochart, Heidegger, Selden, and Buxtorf. The chief argument, alleged by many of them to prove the Hebrew to have been the original language, is taken from the names of perſons mentioned before the confuſion of Babel, which, they ſay, are plainly of the Hebrew derivation; as אדם, Adam, from אדמה, Adamah, the ground; חוה, Eve or Havah, from היה, hajah, vixit, becauſe ſhe was the mother of all living; פלג, peleg, from פלג, peleg, diviſit; and ſeveral others. Theſe, they maintain, are plainly Hebrew names, and therefore prove the Hebrew language to have been in uſe when they were given. Beſides, it is alleged, that the names of ſome nations are derived from Hebrew names, as Ἰαονία, Ionia, from יון, Javan, the ſon of Japhet, and thoſe alſo of ſome heathen gods, as Vulcan, which ſeems to be a corruption of Tubal-cain, and Apollo of Jubal. Grotius, however, and others, will not allow this argument to be concluſive, becauſe there are more patriarchal names for which we can find no ſuch Hebrew derivation, than there are of thoſe which have ſuch derivations; that names occurring in the Moſaic hiſtory were not original names, but probably tranſlated by Moſes into the language in which he wrote; and becauſe ſeveral of theſe names are more particularly derived from ſome other of the oriental tongues than from the Hebrew. But reſuming the conſideration of changes which a language has undergone, the Hebrew, in which fewer of theſe occur than in other languages, claims priority. In order to give this argument its full force, we muſt ſeparate from its original character, for reaſons which ſhall be given under a future article, all Maſoretic additions (ſee Points); we muſt alſo exclude all thoſe prefixes and affixes, which have been ſucceſſively introduced, in order to give it compaſs and preciſion. We muſt reſtrict our attention to the indeclinable radix or root, ſeparate from the various voices, moods, tenſes, numbers and perſons of verbs, and alſo adjectives, and numbers and regimen of nouns, which have been improvements ſubſequent to its original formation; and further recollect that the Hebrew verbs conſiſted originally of three letters, and that they were probably pronounced at firſt as monoſyllables. Thus ſimplifying the language and reſtoring it to a few names of things, perſons, and actions, we ſhall proceed far in vindicating its claim to originality. After all, the moſt probable opinion ſeems to be, that neither the Hebrew, nor Syriac, nor Chaldee, nor any other language now extant, was the true original tongue in ſuch a ſenſe, that all other languages were derived from it as their ſource and matrix; but that this, and the other oriental tongues, were either coeval and perhaps one and the ſame, or that they all ſprung from or are ſo many different dialects of that firſt language, which is itſelf now loſt among them: juſt as the Italian, French, and Spaniſh are none of them the languages of the ancient Romans, but all derived from it. See Language.

The Hebrew language has been highly extolled by its partial advocates, and it is unqueſtionably entitled, on account of its ſimplicity, purity, energy, and other qualities, to commendation. This language is ſaid to abound in the apteſt etymologies and roots of the names both of men and things. The names of brutes expreſs their nature and properties more ſignificantly and more accurately than in any other known language in the world. Its words are conciſe, yet expreſſive, derived from a ſmall number of roots, (its radical words being now no more than about 500, and rarely conſiſting of more than three letters, or two ſyllables, frequently one, and expreſſed by two ſounds,) yet without the ſtudied and artificial compoſitions of the Greek and Roman languages. Its words follow each other without intricacy or tranſpoſition. Above all, notwithſtanding its ſimplicity and conciſeneſs, and purity of original radicals, it has the happieſt and richeſt fecundity in its verbs of any known tongue, either ancient or modern, which is owing to the variety and ſufficiency of its conjugations; by means of which, as Bellarmine obſerves, in his Hebrew grammar, all the variety of ſignifications, into which it is poſſible for a verb to be branched out, are expreſſed with a very ſmall variation of a letter or two, which, in any other language, cannot be done without circumlocution. Properly ſpeaking, it has but one ſimple conjugation, but this is varied in each verb ſeven or eight different ways, which has the effect of ſo many different conjugations, and affords a great number of expreſſions, by which to repreſent, under one ſingle word, all the different modifications of a verb, and ſeveral ideas at once; which in the modern, and moſt of the ancient and learned languages, are expreſſible only by phraſes. It derives alſo great advantage, with reſpect to brevity and variety of expreſſion, from its few prefixes and affixes, which annexed to the radix or root, vary its ſignification almoſt at pleaſure, and when the radix is a verb, exhibit the gender of the object introduced. Its nouns have no flexion beſides that which is neceſſary to indicate the difference of gender and number. Its caſes are diſtinguiſhed by articles, conſiſting of ſingle letters at the beginning of a word; its pronouns are ſingle letters affixed, and the prepoſitions are prefixed to words. Some learned men, ſays Dr. Sharpe (ubi ſupra), will have it to be the language ſpoken by Adam in paradiſe, and that the ſaints will ſpeak it in heaven; alleging, that it is ſo conciſe, and yet ſo ſignificant, ſo pathetic, and yet ſo free from levity or bombaſt, as, of all languages, to approach neareſt to that of ſpirits, who need no words for conveying their ideas to each other.

It

HEBREW LANGUAGE.

It has been ſuppoſed by many very learned men, that the Hebrew characters or letters were often uſed hieroglyphically, and that each had its ſeveral diſtinct ſenſe underſtood as a hieroglyphic. Newmann, who ſeems to have taken infinite pains to find out this ſecret meaning of theſe letters, gives the following explication: א, *aleph*, he ſays, is a character denoting motion, readineſs, and activity; ב, *beth*, ſignifies, 1, matter, body, ſubſtance, thing; 2. Place, ſpace or capacity; and 3. In, within or contained; ג, *gimel*, ſtands for flexion, bending, or obliquity of any kind; ד, *daleth*, ſignifies any protruſion made from without, or any promotion of any kind; ה, *he*, ſtands for preſence, or demonſtrative eſſence of any thing; ו, *vau*, ſtands for copulation or growing together of things; ז, *dſain*, expreſſes vehement protruſion and violent compreſſion, ſuch as is occaſioned by at once violently diſcharging and conſtringing a thing together; it alſo ſignifies, ſometimes, the ſtraightening of any figure into a narrow point at the end; ח, *cheth*, expreſſes aſſociation, ſociety, or a kind of compoſition, or combination of things together; ט, *teth*, ſtands for the withdrawing, drawing back, or receſs of any thing; י, *jod*, ſignifies extenſion and length, whether in matter or in time; כ, *caph*, expreſſes a turning, curvedneſs or concavity; ל, *lamed*, ſtands for an addition, acceſs, impulſe, or adverſation, and ſometimes for preſſure; מ, *mem*, expreſſes amplitude, or the amplifying any thing in whatever ſenſe; in regard to continuous qualities it ſignifies, the adding length, breadth, and circumference; and in disjunct qualities it ſignifies multitude; נ, *nun*, ſignifies the propagation of one thing from another, or of the ſame thing from one perſon to another; ס, *ſamech*, expreſſes cincture and coarctation; ע, *ain*, ſtands for obſervation, objection, or obviation; פ, *pe*, ſtands for a crookedneſs or an angle of any figure; צ, *tſade*, expreſſes contiguity and cloſe ſucceſſion; ק, *koph*, expreſſes a circuit or ambit; ר, *reſh*, expreſſes the egreſs of any thing, as alſo the exterior part of a thing, and the extremity or end of any thing; ש, *ſhin*, ſignifies the number three or the third degree, or the utmoſt perfection of any thing; ת, *tau*, expreſſes a ſequel, continuation, or ſucceſſion of any thing.

According to this explication, as the ſeveral particular letters of the Hebrew alphabet ſeparately ſignify the ideas of motion, matter, ſpace, and the ſeveral modifications of matter, ſpace, and motion, it follows, that a language, the words of which are compoſed of ſuch expreſſive characters, muſt neceſſarily be of all languages the moſt perfect and expreſſive; as the words formed of ſuch letters, according to their determinate ſeparate ſignifications, muſt convey the idea of all the matters contained in the ſenſe of the ſeveral characters, and be at once a name and a definition, or ſuccinct deſcription of the ſubject, and all things material as well as ſpiritual, all objects in the natural and moral world, muſt be known as ſoon as their names are known, and their ſeparate letters conſidered. Whether the Hebrew language merits theſe high encomiums in preference to all others or not, yet its well authenticated antiquity, and the venerable tone of its writings, ſurpaſs any thing left upon record in any other dialect now extant in the world. By this language God has thought fit to convey a great part of his revelations to mankind, and the ſcriptures of the Old Teſtament penned in this language are ſo nearly connected with thoſe of the New, that the ſtudy of it may be recommended to the ſcholar, and particularly to the divine.

In the Hebrew language, which is written from the right to the left hand, there are 22 letters, which are divided by grammarians into *guttural*, *palatal*, *dental*, *labial*, and *lingual*; which diviſion is taken from the ſeveral organs of ſpeech, ſome of which contribute more than others to the pronunciation of certain letters. The letters, with their names, figures, and ſounds, are exhibited in the following table.

Name.	*Figure.*	*Sound.*
Aleph	א	*a*, as in call.
Beth	ב	*b*, never *v*.
Gimel	ג	*g*, hard, as gone.
Daleth	ד	*d*.
He	ה	*h*, or *e*, a gentle aſpiration, as in holy, at the beginning of a word, and â in the end of a word, or ê only.
Vau	ו	*v*, always a vowel.
Zain	ז	*z*, ſoft, like Gr. *zeta*, as in roſe.
Hheth	ח	*hh*, a ſtrong guttural, as *χ*, or *é*, like the Greek *eta*.
Teth	ט	*t*, like the Greek *tau*.
Jod	י	*i*, always a vowel.
Caph	כ	*k*, or *c* hard.
Lamed	ל	*l*.
Mem	מ	*m*.
Nun	נ	*n*.
Samech	ס	*s*.
Ain	ע	*gn*, *ng*, *o* or *á*.
Phe	פ	*p*, *ph*, like Greek *φ*.
Tſade	צ	*tſ*, or *tz*.
Koph	ק	*k* or *q*, Greek *κ*.
Reſh	ר	*r*.
Schin or ſhin	ש	*ſh*, or *s*.
Thau	ת	*th*, or *t*, Greek *θ* or *τ*.

N. B. The following five letters, *viz.* כ מ נ פ צ, are at the end of a word written thus, ך ם ן ף ץ. The two letters א and ל are ſometimes made to coaleſce, thus ﬠ.

Of the above 22 letters 16 are conſonants, and according to the diſtribution of Maſclef, the following ſix are vowels, *viz.* א ה ו ח י ע; four of which, *viz.* א ה ו י are ſimple and ſhort, and two, *viz.* ח and ע, double and long, becauſe they are more ſtrongly aſpirated. Of theſe vowels three are evidently of this character, *viz.* א, ו, and י, *a*, *u*, and *i*; and they have been called "Matres lectionis," or the parents of reading, to which number ſome have added ה, comprifing them all in the technical word אהוי, *ehevi*. According to this arrangement, the vowels in the Hebrew alphabet are,

א	*a*.
ה	*e* ſhort, or Greek *ε*.
ח	*é* long, or Greek *η*.
י	*i* or *y*.
ע	*o*.
ו	*u*.

When theſe vowels occur, it will not be difficult to pronounce Hebrew words; but words and ſyllables often occur, that conſiſt merely of conſonants, and in which none of theſe original vowels are found. If we reject the Maſoretic punctuation, we are aſked how are ſuch ſyllables and words to be enunciated? We may obſerve, in general, that in words of this kind, they are chiefly, if not altogether, the *ſhort* vowels that are wanting: and as no conſonant could be articulated without a ſhort vowel, the Hebrew writers thought it ſufficient, in words deſtitute of long vowels, to note down the conſonants only; concluding, as they might naturally do, that in this abbreviated form the meaning of ſuch words could not be miſtaken by the reader. They, therefore, employed their vowel-characters for the purpoſe of expreſſing the *long* vowels, when theſe conſtituted a radical part of the word. For the ſhort vowels they had no

characters, deeming them unneceſſary. Accordingly ſome have propoſed to inſert a ſhort *a* or *e*, in any combination of conſonants, to facilitate their pronunciation. This method is exceedingly ſimple; whereas the Maſoretic pointing is complex and difficult, and very diſcouraging to a beginner. Maſclef propoſes to ſupply the vowel that is wanted between two conſonants by the auxiliary vowel of the preceding one; that is, by the vowel which immediately follows the firſt conſonant in its artificial denomination. The artificial denomination of בּ is *beth*, of גּ is *ghimel*, of דּ is *daleth*; and of courſe the vowel which follows בּ is *e*, and *e* is its auxiliary vowel, and ſo of the reſt. Suppoſe the word דבר occurs, it would be read *daber*: ſo in פלשת having no vowel, פּ is followed by *e*, ל by *a*, שׁ by *i*, and it would be read *phelaſſith*. Many bibles being, however, ſtill printed on the Maſoretic plan, we ſhall here give a brief account of the Maſoretic points, referring to the article POINTS the diſcuſſion of the time of their introduction and their authority. The vowel-points amount in number to 15, and the accents to about 30. The points may be divided into ſigns of long, ſhort, and very ſhort vowels, as below:

Long vowels.

בָּ bâ, kametz.
בֵּי bê, tzere, *i*.
בִּי bi, chirek-longum,
בֹו bo, cholem.
בּוּ bu, ſhurek, *u*.

Short vowels.

בַ ba, patach.
בֶ be, ſægol.
בִ bi, chirek-breve.
בָ or בֳ bo, kametz-chateph.
בֻ bu, kibbutz, *u*.

Very ſhort vowels.

בֲ ă, chateph-patach.
בֱ ĕ, chateph-ſægol.
בֳ ŏ, chateph-kametz.

N.B. Two dots placed one above the other: are called *ſheva*, which repreſents a very ſhort *e*. It is pronounced only under the firſt letter of a word, under a doubled or daggheſhed letter, after another ſheva, or after a long vowel. In other caſes it is quieſcent. The term *chateph* ſignifies ſhort. The letter שׁ has ſometimes a point above its right branch, and ſometimes above its left; thus שׁ, ſhin, and שׂ, ſin. If the preceding letter wants a point, the right hand point of ſhin is cholem, or ō long. When the letter immediately following has no point, ſhin is furniſhed with two points, thus שׁ, the left one cholem, if there be no point below שׁ; the right cholem, if the preceding letter is unpointed. A dot or point in the middle of a letter is called daggheſh; and the letter is ſometimes doubled by it, in which caſe it is called daggheſh forte; ſometimes it only removes the aſpiration from the letters בּ גּ דּ כּ פּ ת, and it then is called daggheſh lene. A ſimilar point placed in the boſom of ה and ח imports that they are to be ſounded, when otherwiſe they would be ſilent. This point is called mappik. When (־) patach is below the laſt letter of a word, being a guttural, it is to be pronounced before, and not after ſuch letter; it is then called patach furtivum. וֹ repreſents two vowels and a conſonant; with a point above, it is a cholem; with a point in its boſom, it is ſchurek, but if it has a point below, it becomes the conſonant *v*. For an account of the Hebrew accents, ſee ACCENTS.

We have already obſerved, as an excellence of the Hebrew language, and as a circumſtance that conduces to its ſimplicity and conciſeneſs, that the relations of nouns are diſtinguiſhed by particles or prepoſitions prefixed; and the perſons, modes, or tenſes of verbs are marked by means of letters of a particular order, which ſometimes appear in the middle, ſometimes in the beginning, and ſometimes at the cloſe of the original word. With this view, all the letters of the alphabet are divided into two claſſes, denominated *radical* and *ſervile*, the former conſtituting primitive words, called *roots*, and the latter derivatives, which are employed in all the various flexions of words. The roots, as we have already obſerved, are generally verbs, conſiſting commonly of three letters. All the letters may be radical, but the appellation is appropriated to 11, becauſe they can never be ſervile. The other 11 letters are denominated ſerviles, and by theſe the whole buſineſs of flexion, derivation, numbers, genders, perſons, and tenſes, is accompliſhed.

Pure radicals.	Serviles.
ג ד כ ל ם מ ן נ ס ע פ צ ק ר	א ה ו י ב ת ם ן נ ס ש ת

The caſes of nouns are diſtinguiſhed, not by their terminations, but by letters or prepoſitions prefixed; as in the following example.

Nom.	מלך	rex,
Gen.	המלך	regis,
Dat.	למלך	regi,
Accuſ.	אתמלך	regem,
Voc.	המלך	o rex,
Ablat.	ממלך	á rege.

Maſculine nouns form their plural by ים, added to the ſingular, and feminines by adding וֹת to the ſingular. All the ſervile letters uſed as prefixes to nouns are comprehended in this technical memorial משחּ וכלב. Adjectives and participles are often uſed as ſubſtantives; in which caſe the definite article ה is often prefixed to them. Theſe are frequently placed after the ſubſtantive; and a ſingular or plural adjective is ſometimes joined with a plural or ſingular ſubſtantive. Sometimes the termination of the adjective is feminine when the ſubſtantive is maſculine. Degrees of compariſon are commonly expreſſed by adverbs or prepoſitions. The ſuperlative degree is expreſſed by a repetition of the poſitive, or ſubjoining the name of God to words *in ſtatu regiminis*. Nouns ſtanding alone, or independent of other words, are ſaid to be *in ſtatu abſoluto*; but when they are placed before ſubſtantives, differing in ſignification, they are ſaid to be *in ſtatu regiminis* or *conſtructo*. The word *in regimine* ſometimes undergoes no change, and its regimen is only known by juxtapoſition. Words in this ſtate admit of a change of ים in maſculine plurals into י, or by expunging ם; and ה the mark

mark of the feminine ſingular is changed into ת. Of *Affixes* and *ſuffixes*, ſee theſe terms.

Verbs, as we have before ſaid, have, ſtrictly ſpeaking, only one conjugation, or are indeclinable. The radical word remains unvaried, and the inflexion is carried on by ſervile letters. The conjugations in the Hebrew language are denoted by the technical terms of kal, niphal, hiphil and hophal, and hithpahel; which names are derived from the old theme פעל, *operatus eſt*, which was the model of verbs, the middle letter ע being pronounced as a ſtrong guttural. Kal, *i. e.* lævis, denotes the pure root, unburdened with ſervile letters, and repreſents the active voice. *Niphal* is the paſſive of kal, and is formed by fixing נ to the radical letters. *Hiphil*, in the active voice, is formed by prefixing ה to the firſt radical, and inſerting י betwixt the ſecond and third. It ſignifies to cauſe or command another to perform the action of the verb; and its paſſive is *hophal*. *Hithpahel* bears a near reſemblance to the middle voice of the Greeks; it is formed by prefixing התּ to the radical letters, and commonly ſignifies to perform the action of the verb to one's ſelf, or frequently to repeat the action. The letters prefixed to the radical letters or inſerted between them are called the "characteriſtics" of the conjugations. Hebrew verbs have only three moods; *viz.* the indicative, imperative and infinitive. The future is often uſed for the imperative, and the ſubjunctive or optative mood is expreſſed by conjunctions placed before the indicative. All verbs are declined by fragments of the perſonal pronouns, prefixed or ſubjoined to the radical letters. Hebrew verbs are *perfect* or *defective*, perfect when they retain all their radical letters through every mood and form; and defective when they reject one or more radical letters in ſome of their parts.

Nouns are formed from verbs, 1. By abſtraction of radical letters; 2. By commutation of radical letters; 3. By prefixion of ſerviles; 4. By inſertion of the ſame; and 5. By addition of the ſame. Nouns formed by the prefixion or addition of ſerviles are denominated *heëmantic*, becauſe the letters which compoſe the word האמנתי, *credidi*, are employed in their formation; and to the number may be added the letter ך. For the letters expreſſing numbers in the Hebrew language, ſee CHARACTER. For the *keri* and *chetib*; ſee theſe articles. For the Hebrew ſyntax, ſee SYNTAX. The following directions will ſerve for finding the root and reſtoring the radical letters. 1. Reject the ſerviles, and if three pure radicals remain, theſe conſtitute the root. 2. If two remain, as is commonly the caſe, in abbreviated roots, prefix to theſe either נ or י, or inſert ו betwixt them, or poſtpone ה, or double the ſecond. On the ſubject of the Hebrew language, ſee Maſclef's Grammatica Hebræa, 1743, tom. i. Wilſon's Elements of Hebrew Grammar, ed. 2. 1788. Robertſon's Editio Secunda Grammaticæ Hebrææ, &c. Edinb. 1783. See MASORA and POINTS.

HEBREW, *Rabbinical*, or *Modern Hebrew*, is the language uſed by the rabbins, in the writings they have compoſed. The baſe, or body hereof, is the Hebrew and Chaldee, with divers alterations in the words of theſe two languages, the meanings whereof they have conſiderably enlarged and extended. Abundance of things they have borrowed from the Arabic: the reſt is chiefly compoſed of words and expreſſions, chiefly from the Greek; ſome from the Latin; and others from the other modern tongues; particularly that ſpoken in the place where each rabbin lived or wrote.

The rabbinical Hebrew muſt be allowed a very copious language. Mr. Simon, in his "Hiſt. Crit. du. Vieux Teſtam," liv. iii. chap. 27, obſerves that there is ſcarce any art or ſcience, but the rabbins have treated thereof in it. They have tranſlated moſt of the ancient philoſophers, mathematicians, aſtronomers, and phyſicians; and have wrote themſelves on moſt ſubjects: they do not want even orators and poets. Add, that this language, notwithſtanding it is ſo crowded with foreign words, has its beauties viſible enough in the works of thoſe who have written well in it.

M. Simon ſays, it is impoſſible to reduce it into an art, or ſyſtem of rules; but ſeveral learned men are of another ſentiment; and it not only appears poſſible, but has actually been performed. Genebrard firſt attempted it in his "Iſagoge Rabbinica," which yet goes no farther than the learning to read it. Buxtorf ſeconded him, at the end of his Hebrew Grammar; where we have an additional piece, under the title "Lectionis Hebreæo-Germanicæ Uſus & Exercitatio." Others have gone yet farther: Maius has given us a rabbinical grammar, at Gieſſen, under the title of "Johannis Maii Grammatica Rabbinica;" and before him Sennert had done the ſame; "Rabbiniſmus: i. e. Præcepta Targumico-Talmudico-Rabbinica." Wirtemb. an. 1666.

HEBREW *Muſic*. Notwithſtanding the unremitting labours of the firſt fathers of the church, and the learning and diligence of innumerable tranſlators and commentators, but few materials of great importance can be acquired for this article in the muſical department, except what the Bible itſelf contains; as the firſt periods of the hiſtory of the ancient Hebrews, from its high antiquity, can receive no illuſtration from cotemporary hiſtorians, or from human teſtimony.

The chief part, therefore, of what we have to do, is to collect the principal paſſages relative to thoſe early ages of the world, the tranſactions of which are recorded in the ſacred writings with true and genuine ſimplicity, and to arrange them in chronological order; a taſk which, however trivial and eaſy it may ſeem, will not be without its uſe in a General Hiſtory of Muſic; as it will at leaſt ſhew, that this art has always had admiſſion into the religious ceremonies, public feſtivals, and ſocial amuſements of mankind.

The conſtruction and uſe of muſical inſtruments have a very early place among the inventions attributed to the firſt inhabitants of the globe, by Moſes: for, Geneſis, chap. iv. ver. 21, Jubal, the ſixth deſcendant from Cain, is called "the father of all ſuch as handle the harp and organ."

But though this circumſtance is mentioned ſo ſoon in the Pentateuch, yet it could have happened but a ſhort time befor the deluge, A. M. 1656; conſequently the world muſt have been peopled many centuries before the invention took place. And with reſpect to the inſtrument called an *organ*, in the Engliſh verſion of this paſſage, it muſt not be imagined that ſuch a noble and complicated machine is there implied, as the preſent inſtrument of that name. In the Hebrew it is called *huggab*, which, ſay the commentators, was a kind of ſyrinx, or fiſtula. The Septuagint, inſtead of harp and organ, has ψαλτηριον και κιθαραν, *pſaltry* and *cithara*; the Syriac, *citharam* et *fides*; Chaldæan paraphraſe, *ipſe fuit magiſter omnium canentium in nablio, ſcientium cantium citharæ et organi*. *Nablion* is the Hebrew word for harp. The Arabic has *tympanum et citharam*; and the French has *le violon et les orgues*.

Hence it appears, that the tranſlators, ancient and modern, of all parts of the world, not knowing what were the real forms and properties of the Hebrew inſtruments, have given to them the names of ſuch as were of the moſt common uſe in their own countries.

No mention, however, is made in the ſcriptures of the practice of muſic, till more than ſix hundred years after the deluge. But in Geneſis xxxi. and 26th and 27th verſes, about

about 1739 years before Chriſt, according to the Hebrew chronology, both vocal and inſtrumental muſic are ſpoken of as things in common uſe.

"And Laban ſaid to Jacob, what haſt thou done, that thou haſt ſtolen away unawares to me, and carried away my daughters, as captives taken with the ſword?"

"Wherefore didſt thou flee away ſecretly, and ſteal away from me? and didſt not tell me, that I might have ſent thee away with mirth and with ſongs, with tabret, and with harp?"

Laban was a Syrian, and brother to Rebecca, Iſaac's wife; ſo that the tabret and the harp ſhould be ranked among Aſſyrian inſtruments.

After this time the ſacred text furniſhes no muſical incident, till the year 1491 before Chriſt, when we have the firſt hymn, or pſalm, to the Supreme Being, upon record. It contains the pious effuſions of Moſes, after the paſſage of the Red ſea, at the head of the whole people of Iſrael, juſt eſcaped from bondage.

"Then ſang Moſes and the children of Iſrael this ſong unto the Lord, and ſpake, ſaying, I will ſing unto the Lord, for he hath triumphed glorioufly," &c. Exod. xv.

Moſes is ſeconded on this occaſion by Miriam, the propheteſs, and ſiſter of Aaron, who "took a timbrel in her hand, ver. 20; and all the women went out after her with timbrels and with dances."

"And Miriam anſwered them, ſing ye to the Lord," &c.

Here is an early inſtance of women being permitted to bear a part in the performance of religious rites, as well as of vocal muſic being accompanied by inſtrumental, and by dancing.

St. Stephen tells us (Acts, vii. ver. 21, 22.) that Moſes, having been educated by Pharaoh's daughter "as her own ſon, was learned in all the wiſdom of the Egyptians." And Clemens Alexandrinus particularizes his acquirements, by affirming that "he was inſtructed in his maturer age by the Egyptians in all liberal ſciences, as arithmetic, geometry, rhythm, harmony, but, above all, medicine and muſic."

However, in the infancy of a ſtate, a nation has but little leiſure for cultivating muſic any otherwiſe than as it is connected with religious rites and the military art. Accordingly we find no other muſical inſtrument mentioned during the adminiſtration of the great Hebrew legiſlator, than trumpets, except the timbrel, uſed by Miriam. Numb. chap. x. 2. he is ordered by divine command to make two trumpets of ſilver of a whole piece, "for aſſembling together the people, and for journeying the camps." And in the eight following verſes all the ſignals to be ſounded by one and by two trumpets are regulated. But theſe inſtruments ſeem to differ from that of the jubilee, in nothing but the materials of which they were made: as the Hebrew text, and the ſeveral verſions, agree in calling all by one name.

The feaſt of trumpets inſtituted by Moſes, Numb. xxix. 1. in the month of September, is imagined to have been the celebration of harveſt home. "And in the ſeventh month, on the firſt day of the month, ye ſhall have a holy convocation; ye ſhall do no ſervile work; it is a day of blowing the trumpets unto you." The rigid obſervance of the Sabbath upon every ſeventh day, rendered ſeven a ſacred number among the Hebrews. Hence, not only the ſeventh day, but the ſeventh week, the ſeventh month, the ſeventh year, and ſeven times ſeventh year, were kept holy: "and on the fiftieth year thou ſhall cauſe the trumpet of the jubilee to ſound throughout the land." Levit. xxv. 9.

The trumpets of rams horns uſed at the ſiege of Jericho, ſeem to have been leſs muſical inſtruments, than military ſignals for the aſſailant to march and ſhout by, in order, by their noiſe, to terrify and diſmay the enemy.

Upon this occaſion all the powers of the number ſeven were put in practice. "Seven prieſts ſhall bear before them ſeven trumpets, and the ſeventh day ye ſhall compaſs the city ſeven times, and the prieſts ſhall blow with the trumpets." Joſh. vi. 4.

No further mention is made of muſic, till the ſong of Deborah and Barak, Judges v. which ſeems to have been ſung in dialogue, and wholly without inſtruments. It was about fifty years after this period, and eleven hundred and forty-three years before Chriſt, that the unfortunate daughter of Jephtha, upon hearing of her father's victory over the Ammonites, went out to meet him with timbrels and with dances: Judges ii. 34. From this time till Saul was choſen king, 1095, B. C. the ſacred text is wholly ſilent about every ſpecies of muſic, except that of the trumpet in military expeditions.

But here an incident occurs, which ſeems to merit particular attention. It appears from many paſſages in ſcripture, that muſic was as nearly allied to prophecy as to poetry.

When Samuel, after ſecretly anointing Saul king, inſtructs the new monarch in the meaſures he is to purſue for eſtabliſhing himſelf on the throne, he ſays, "And it ſhall come to paſs, when thou art come to the city (Bethel,) that thou ſhalt meet a company of prophets coming down from the high place, with a pſaltery and tabret, and a pipe, and a harp before them, and they ſhall propheſy. And the ſpirit of the Lord will come upon thee, and thou ſhalt propheſy with them."

Who is ignorant, ſays Quintilian, that muſic in ancient times was ſo much cultivated, and held in ſuch veneration, that muſicians were called by the names of *prophets* and *ſages?*

Vates, in Latin, is a common term for *prophet*, *poet*, and *muſician*. Clemens Alexandrinus, deſcribing the different kinds of Egyptian prieſts, and their functions, ſays, that the principal of them were called *prophets*. The oracles of the ancients were delivered in ſong; and the Pythian prieſts, who compoſed into hexameter verſe the looſe and disjointed expreſſions of the agonizing Pythia, were ſtyled *prophets*, προφηται. Theſe, according to Plutarch, "were ſeated round the ſanctuary, in order to receive the words of the Pythia, and incloſe them immediately into a certain number of verſes, as liquors are incloſed in bottles."

The improviſatori of Italy are ſtill accompanied by an inſtrument, like the prophets of old; and Italian poets, who write down verſes, ſing at the time of compoſing them.

The examples in ſcripture of this union of muſic and prophecy are numerous. "Moreover, David, and the captains of the hoſt, ſeparated to the ſervice of the ſons of Aſaph, and of Heman, and of Jeduthun, who ſhould propheſy with harps, with pſalters, and with cymbals.—Of the ſons of Aſaph, four, who propheſied according to the order of the king:—Of Jeduthun, ſix, who propheſied with a harp, to give thanks and to praiſe the Lord. And of the ſons of Heman, the king's ſeer, in the words of God, fourteen, to lift up the horn."

But the moſt ſtriking example of the cuſtom practiſed by the prophets, of tranquillizing their minds, and exciting in themſelves divine inſpiration, by means of muſic, is in the ſecond book of Kings.

The three ſovereigns of Iſrael, Judah, and Edom, marching with their armies through a wilderneſs, were all upon the point of being deſtroyed by thirſt, as there was no water to be found in their paſſage, either for man or beaſt.

"And

"And the king of Iſrael ſaid, alas! that the Lord hath called theſe three kings together, to deliver them into the hand of Moab. But Jehoſhaphat ſaid, is there not here a prophet of the Lord, that we may enquire of the Lord by him? And one of the king of Iſrael's ſervants anſwered and ſaid, here is Eliſha, the ſon of Shaphat. So the king of Iſrael and Jehoſhaphat, and the king of Edom, went down to him.—And Eliſha ſaid, bring me a minſtrel. And it came to paſs when the minſtrel played, that the hand of the Lord came upon him, and he ſaid, "Thus ſaith the Lord, make this valley full of ditches," &c.

David, by having cultivated muſic ſo early in youth, ſeems to have been intended by his family for the *profeſſion* of a prophet. St. Ambroſe ſays, that he had always the gift of prophecy, and was choſen by God himſelf, in preference to all other prophets, to compoſe pſalms. (Præf. in Pſal. i.) See DAVID.

It has ever been the cuſtom of legiſlators and founders of religion, in compliance with the prejudices of mankind, to retain part of the former laws and religious inſtitutions. The Egyptians divided the inhabitants of their country into caſts, or tribes, confining each profeſſion to one family. And as muſic was many ages confined by them to the prieſthood, and to religious purpoſes, the Hebrews, who had their arts and ſciences from the Egyptians, and who adopted many of their religious rites, as the primitive Chriſtians did afterwards thoſe of the Pagans, in order to conciliate parties, and facilitate the eſtabliſhment of a new worſhip, made both prieſts and muſicians hereditary in the tribe of Levi. "And the ſons of Aaron the prieſts ſhall blow with the trumpets, and they ſhall be to you for an ordinance for ever, throughout your generations." Accordingly, during the life of Moſes, none but the prieſts blew the trumpets, whether in peace or war: as, afterwards, in Joſhua's adminiſtration, both at the ſiege of Jericho, and upon all other occaſions, we find the office of blowing the trumpets was ſtill confined to the prieſthood; and, when David firſt regulated the muſical eſtabliſhments, for the ſervice of religion, it appears, that not only the ſelect band of ſinging men and ſinging women, but all the four thouſand performers upon inſtruments, were choſen from the families of prieſts and Levites.

Of the muſical inſtruments of the Hebrews, ſo often mentioned in the Pſalms, ſo diſcordant are the commentators on the ſubject, that no preciſe or ſatisfactory idea can be ſuggeſted on the ſubject. If, indeed, the leaſt ray of hope remain, that a true idea of Jewiſh inſtruments can ever be acquired, it muſt be from the arch of Titus at Rome, where it is ſuppoſed that the ſpoils brought by that emperor from Jeruſalem have been exactly repreſented in ſculpture. Among theſe are ſeveral muſical inſtruments, particularly the ſilver trumpets, called by the Hebrews *chatzotzeroth*; and horns, ſuppoſed to reſemble the ſhawms, mentioned ſo often in ſcripture, called in Hebrew *keranim*, or *ſacerdotal trumpets*.

But the arch upon which theſe inſtruments are ſculptured, though, according to Venuti, of excellent workmanſhip, was not erected till after the death of Titus; and, to ſay the truth, the inſtruments are of no uncommon form. The trumpets are long ſtraight tubes, as modern trumpets would be, if not folded up, for the convenience of the player; and the horns are ſuch as frequently occur in ancient ſculpture. Examples of both may be ſeen in Blanchini, Bartholinus, Montfaucon, Padre Martini, and all the writers upon ancient muſic.

The reign of Solomon, ſo long, ſo pacific, and ſo glorious to the Hebrews, may be regarded as the Auguſtan age of that people; whoſe proſperity, during this period, not only enabled them to cultivate arts and ſciences among themſelves, but ſtimulated foreigners to viſit and aſſiſt them. And as we find that the Romans, during the time of Auguſtus, and and his ſucceſſors, were indebted to the Greeks for a great part of their knowledge in the polite arts, ſo the Hebrews, under Solomon's government, had aſſiſtance from Egypt and from Tyre. Riches and renown never fail to attract talents into a country from neighbouring kingdoms. As to muſic and poetry, which were put upon ſo reſpectable a footing in the former reign, they ſeem to have had their ſhare of attention in this; particularly in the ſervice of the temple, at the dedication of which, if we may credit Joſephus, "Solomon made two hundred thouſand trumpets, according to the ordinance of Moſes: (Moſes was ordered to make two trumpets of ſilver only. Numb. x. 2.) and forty thouſand inſtruments of muſic (as if trumpets were not inſtruments of muſic) to record and praiſe God with, as the pſaltery and harp of electrum," a mixed metal, of which, according to Pliny, four parts were gold, and the fifth part was ſilver. Joſephus has often been accuſed of inaccuracy in other things; and with reſpect to muſic, his accounts neither bear the marks of judgment nor fidelity; but we have information from much better authority, "That Solomon appointed, according to the order of David his father, the courſes of the prieſts to their ſervice, and the Levites to their charges, to praiſe and miniſter before the prieſts, as the duty of every day required."

It is the opinion of many expounders and commentators of the ſacred writings, that Solomon was author of ſome of the Pſalms that are attributed to David. Of this we are certain, that he was no leſs fond of poetry than his father. In the firſt of Kings, iv. and xxv. we are told that "he ſpake three thouſand proverbs: and his ſongs were a thouſand and five." But whether, like the royal Pſalmiſt, he was a practical muſician, does not appear in the records of his reign. However, in Eccleſiaſtes, ii. 8. we find muſic mentioned by this voluptuous prince among the vain luxuries and vexations of ſpirit, with which he found himſelf ſatiated: "I gat me men-ſingers and women-ſingers, and the delights of the ſons of men, as muſical inſtruments, and that of all ſorts:" which is all that can be gathered on the ſubject of muſic during this ſplendid reign.

A century paſſed from the dedication of the temple, without the mention of any thing remarkable in ſcripture concerning the muſic of the Hebrews, except the paſſage already cited, where Eliſha calls for a minſtrel to awaken inſpiration, previous to his propheſying.

In the year 896, B. C. the ſingers are ſaid to have contributed greatly towards obtaining a ſingular advantage in favour of Jehoſhaphat, over the Ammonites and Moabites; the muſicians following the camp in the ſame order as they ſerved in the temple, marched as a vanguard in the field with their inſtruments: "And the Levites of the children of the Kohathites, and the children of the Korahites, ſtood up to praiſe the Lord God of Iſrael with a loud voice on high.—And when Jehoſhaphat had conſulted with the people, he appointed ſingers unto the Lord, and that ſhould praiſe the beauty of holineſs as they went out before the army, and to ſay, praiſe the Lord, for his mercy endureth for ever. And when they began to ſing and to praiſe, the Lord ſet ambuſhments againſt the children of Ammon, Moab, and Mount Seir, which were come againſt Judah, and they were ſmitten."

The Hebrews frequently attributed their ſucceſs in battle to the animation given the troops by the trumpets, which were always blown by prieſts and Levites, whom the people highly reverenced, and regarded as inſpired perſons.

"And

"And behold, God himſelf is with us, for our captain, and his prieſt with ſounding trumpets, to cry alarm againſt you.—And when Judah looked back, behold the battle was before and behind, and they cried unto the Lord, and the prieſts ſounded with the trumpets. Then the men of Judah gave a ſhout; and it came to paſs as the men of Judah ſhouted, that God ſmote their enemies."

It was, in like manner, the part of the ancient Gallic, German, and Britiſh druids, who were not only prieſts, but muſicians, to animate their countrymen to the fight.

Thus far we have only had to ſpeak of the cultivation and improvement of muſic among the Hebrews; we have little more to add, except what will indicate its neglect and decline.

But few memorials remain concerning it, from the victory obtained by Abijah, till the captivity and deſtruction of Jeruſalem and the temple, by the Babylonians, in the reign of Jehoiakim. Before this period, muſic, and other ſacred rites, had been frequently much corrupted, during the wars, and by intercourſe with foreign nations; and at every attempt to reſtore them to their former purity and ſplendour, we find the number of thoſe employed in the ſervice of the temple diminiſhed, and their efforts more feeble and ineffectual. At the reſtoration of the royal family, after the crown had been uſurped by Athaliah, we are told that "the princes and the trumpets ſtood by the king: and all the people of the land rejoiced, and ſounded with trumpets, alſo the ſingers with inſtruments of muſic; and ſuch as taught to ſing praiſe." And Jehoiada, during the minority of Joaſh, "appointed the offices with rejoicing, as it was ordained by David." B. C. 878. And in this reign we find that "the ſingers, the ſons of Aſaph," were reſtored to their places.

Theſe continued, however, but a ſhort time in the miniſtry, before they were driven out, and the king and people became proſelytes to another form of worſhip. But after various revolutions both in religion and government, a powerful attempt was made, during the reign of Hezekiah, about 726 years B. C. to reſtore the temple to all its ancient ſplendour.

"And he ſet the Levites in the houſe of the Lord with cymbals, with pſalteries, and with harps, according to the commandment of David.—And the Levites ſtood with the inſtruments of David, and the prieſts with the trumpets.—But the prieſts were too few" to perform all the ceremonies formerly ſolemnized in the temple. However, "there was now great joy in Jeruſalem; for ſince the time of Solomon, there was not the like in Jeruſalem."

But this happy period was of ſhort continuance; new ſchiſms and new misfortunes ſoon put an end to it. And in the year 606, B. C. the Hebrew nation was ſubdued; the temple plundered and deſtroyed; and, ſoon after, both king and people were, by Nebuchadnezzar, ſent captives to Babylon.

During the ſeventy years captivity, it is natural to ſuppoſe that the Hebrews were denied the celebration of their religious rites; nor could they have much time or inclination for domeſtic amuſements or feſtivity; ſo that muſic, the child of leiſure and happineſs, and parent of innocent pleaſure, muſt have been neglected, and ſhut out of their houſes, as an unwelcome gueſt. The idea of every thing that awakened recollection of former felicity, muſt have been painful in a ſtate of ſlavery. "By the waters of Babylon we ſat down and wept: when we remembered thee, O Sion. As for our harps we hanged them up upon the trees that are therein. For they that led us away captives, required of us then a ſong, and melody in our heavineſs: Sing us one of the ſongs of Sion. How ſhall we ſing the Lord's ſong in a ſtrange land? If I forget thee, O Jeruſalem, let my right hand forget her cunning."

Theſe are the natural ſentiments and feelings of a people but lately fallen from a ſtate of proſperity and happineſs, into that of bondage and miſery.

All that has been hitherto collected relative to the muſic of the Hebrews, only ſhews that it was in general uſe among them, from the time of their quitting Egypt, till they ceaſed to be a nation; but what kind of muſic it was with which they were ſo much delighted, no means are now left to determine. That they had their firſt muſic and inſtruments, whatever they were, from the Egyptians, appears to admit of no doubt; but theſe ſeemed to have remained in a very rude ſtate till the reigns of David and Solomon, when, perhaps, they were more improved in quantity than quality; for the great number of Levites, of ſinging men and ſinging women, as well as of trumpets, ſhawms, cornets, ſacbuts, cymbals, and timbrels, could only augment the noiſy cry of joy, or the clamour of petition.

However, we have no authentic account of any nation, except the Egyptians, where muſic had been cultivated ſo early as the days of David and Solomon, the brighteſt period of the Jewiſh hiſtory, the Greeks at that time having hardly invented their rudeſt inſtruments: for Homer and Heſiod, the refiners, if not the inventors, of Greek poetry; and Orpheus, Muſæus, and Linus, to whom they attribute the invention of their muſic and inſtruments, all flouriſhed, according to ſir Iſaac Newton, after theſe Hebrew monarchs.

With reſpect to the modern Jewiſh muſic, we have been informed by a Hebrew high prieſt, that all inſtrumental, and even vocal performances, have been baniſhed the ſynagogue ever ſince the deſtruction of Jeruſalem: that the little ſinging now uſed there is an innovation, and a modern licence; for the Jews, from a paſſage in one of the prophets, think it unlawful, or at leaſt unfit, to ſing or rejoice before the coming of the Meſſiah, till when they are bound to mourn and repent in ſilence: but the only Jews now on the globe, who have a regular muſical eſtabliſhment in their ſynagogue, are the Germans, who ſing in parts; and theſe preſerve ſome old melodies, or ſpecies of chants, which are thought to be very ancient. At Prague they have an organ. The ſame prieſt ſays that, being at Peterſburg ſome years ſince, the grand caliph of Perſia was there likewiſe on an embaſſy, and had the ſervice of his religion regularly performed in a kind of moſque fitted up in the czar's palace for his uſe. That when he firſt heard this ſervice performed, he found the ſinging ſo like that in the German ſynagogues, that he thought it had been done in deriſion of the Jews, and on that account ſoon left. But, upon enquiry, finding it to be nothing more than the manner of ſinging common in Perſia, he concluded that the Perſians had borrowed this kind of chant from the ancient Oriental Jews. At preſent, he ſays, they ſing it firſt ſingle, and then add parts to it, in a kind of chorus, like the German Jews.

Padre Martini has inſerted from the "Eſtro-Poetico-Armonico" of Marcello, 1724, and from an inedited MS. by the cavaglier Ercole Bottrigari, called "Il Trimerone de' Fondamenti Armonici," 1599, a great number of ſuch Hebrew chants as were ſung in the ſynagogues of different parts of Europe, at the time when theſe works were compoſed. But as no two Jewiſh congregations ſing theſe chants alike, if tradition has been faithful in handing them down from the ancient Hebrews to any one ſynagogue, who ſhall determine to which ſuch permanence can be attributed.

HEBREW *Poetry* deſerves particular notice, not only on account of its intrinſic excellence, but becauſe the moſt admirable

mirable and intereſting ſpecimens of it are contained in the ſacred writings of the Old Teſtament, to which our attention is and ought to be frequently directed. While the hiſtorical books, and legiſlative writings of Moſes, are evidently proſaic in the compoſition, the book of Job, the Pſalms of David, the Song of Solomon, the Lamentations of Jeremiah, a great part of the prophetical writings, and ſeveral paſſages ſcattered occaſionally through the hiſtorical books, bear the moſt plain and diſtinguiſhing marks of poetical writing. We can have no reaſon for doubting that theſe were originally written in verſe or ſome kind of meaſured numbers; though as the ancient pronunciation of the Hebrew language is now loſt, we are not able to aſcertain, or at moſt very imperfectly, the nature of the Hebrew verſe. Let any perſon read the hiſtorical introduction to the book of Job, contained in the firſt and ſecond chapters, and then proceed to Job's ſpeech in the beginning of the third chapter, and it muſt appear that he paſſes all at once from the region of proſe to that of poetry. He is warned of the change, not merely by the poetical ſentiments and the figured ſtyle; but by the ſenſible alteration that occurs in the cadence of the ſentence and the arrangement of the words:—a change as great as when he paſſes from reading Cæſar's Commentaries to read Virgil's Æneid. The peculiar excellence of the Hebrew poetry muſt alſo appear, when we conſider that its origin and earlieſt application, as biſhop Lowth obſerves, have been clearly traced into the ſervice of religion. To celebrate in hymns and ſongs to the praiſe of Almighty God; to decorate the worſhip of the Moſt High with all the charms and graces of harmony; to give force and energy to the devout affections were the ſublime employment of the ſacred muſes. The ſame learned author adds, it is more than probable, that the very early uſe of ſacred muſic in the public worſhip of the Hebrews contributed not a little to the peculiar character of their poetry, and might impart to it that appropriate form, which, though chiefly adapted to this particular purpoſe, it nevertheleſs preſerves on every other occaſion. In the Old Teſtament we have ample evidence, that muſic and poetry were cultivated from the earlieſt times among the Hebrews. In the days of the Judges we find mention of the ſchools or colleges of the prophets, in which perſons were educated for the purpoſe of ſinging the praiſes of God, with the accompaniment of various inſtruments. (See 1 Sam. x. 7.) In the days of king David muſic and poetry were carried to their greateſt height. For the ſervice of the tabernacle he appointed 4000 Levites, divided into 24 courſes, and marſhalled under ſeveral leaders, whoſe ſole buſineſs it was to ſing hymns, and to perform the inſtrumental muſic in the public worſhip. Aſaph, Heman, and Jeduthun, were the chief directors of the muſic; and from the titles of ſome pſalms we may infer that they were alſo excellent compoſers of hymns or ſacred poems. We have an account in 1 Chron. ch. xxv. of David's inſtitutions, pertaining to the ſacred muſic and poetry; which were more coſtly, ſplendid, and magnificent, than any which ever obtained in the public ſervice of any other nation. (See HEBREW *Muſic*.)

The general conſtruction of the Hebrew poetry is of a ſingular nature, and peculiar to itſelf. It conſiſts in dividing every period into correſpondent, for the moſt part into equal members, which anſwer to one another, both in ſenſe and ſound. In the firſt member of the period a ſentiment is expreſſed; and in the ſecond member the ſame ſentiment is amplified, or is repeated in different terms, or ſometimes contraſted with its oppoſite; but in ſuch a manner that the ſame ſtructure, and nearly the ſame number of words is preſerved. This is the general ſtrain of all the Hebrew poetry; inſtances of which occur in almoſt every part of the Old Teſtament, particularly in Pſalm xcvi. (See PARALLELISM.) This form of poetical compoſition among the Hebrews has been ſatisfactorily deduced by the learned biſhop, of whoſe work we are now availing ourſelves, from the manner in which they were accuſtomed to ſing or chant their ſacred hymns. They were accompanied with muſic, and they were performed by choirs or bands of ſingers and muſicians, who anſwered alternately to each other. Thus, *e. g.* one band began the hymn with the words: "The Lord reigneth, let the earth rejoice:" then the chorus, or ſemichorus, took up the correſponding verſicle: "Let the multitudes of the iſles be glad thereof." "Clouds and darkneſs are round about him," ſung the one: the other replied, "Judgment and righteouſneſs are the habitation of his throne." In this manner their poetry, when ſet to muſic, naturally divided itſelf into a ſucceſſion of ſtrophes and antiſtrophes correſponding to each other: and hence it is probable, the antiphon, or reſponſory, in the public religious ſervice of many Chriſtian churches, derived its origin. Thus, as we learn from the book of Ezra (ch. iii. 11.), the Levites ſung, alternatim or by courſe: and ſome of David's pſalms bear evident ſignatures of having been compoſed in order to be performed in this manner. This was particularly the caſe with reſpect to the 24th Pſalm; the mode of performing which is particularly illuſtrated by Dr. Lowth, and it muſt have had a very noble and impreſſive effect. The mode of compoſition above ſtated prevailed in the prophetical writings as much as in the Pſalms of David. (See Iſaiah, lx. 1.) However, independently of the ſolemn majeſty which this form of conſtruction gave to the ſacred poetry of the Hebrews, it was in itſelf diſtinguiſhed by the higheſt beauties of ſtrong, conciſe, bold, and figurative expreſſions. Conciſeneſs and ſtrength are two of its moſt remarkable characteriſtics. To the conciſeneſs and ſobriety of expreſſion of the Hebrew poetical writers, their poetry is indebted for much of its ſublimity; and all writers, ſays Dr. Blair, who attempt the ſublime, might profit much by imitating, in this reſpect, the ſtyle of the Old Teſtament. (See SUBLIME.) Bold and animated figures abound in the ſacred books: and we find recurring inſtances of metaphors, compariſons, allegories, and perſonifications. The Hebrew poets borrow their metaphors and compariſons from the country in which they lived; and they preſent to us a very beautiful view of its natural objects, and of the arts and employments of their common life. We cannot forbear evincing the truth of this remark by appropriate examples, deduced from the particular circumſtances of the land of Judea. During the ſummer months this country had little or no rain, and on this account it was much parched; want of water was grievouſly diſtreſſing; and the refreſhment and benefit which were derived from a plentiful ſhower, and the burſting forth of a rivulet, were very ſenſibly experienced by the inhabitants of Judea. Images of diſtreſs or of proſperity deduced from theſe circumſtances frequently occur. (See Iſaiah, ch. xxxv. 1, 6, 7.) Judea was alſo a hilly country, and during the rainy months ſubject to frequent inundations from the ruſhing of torrents, deſcending ſuddenly from the mountains, and from the annual overflowing of Jordan. Great calamities are therefore often compared to the overflowing torrent. (Pſalm, xlii. 7.) Lebanon and Carmel were two of the moſt remarkable mountains of the country; the former noted for its height and the lofty cedars that covered it, and the latter for its beauty and fertility, the richneſs of its vines and olives. In reference to theſe, ſee Iſaiah, ch. xxxv. 2. Solomon's Song, v. 15. vii. 5. Earthquakes were not unfrequent in Judea; and the tempeſts of hail,

hail, thunder, and lightning, accompanied with whirlwinds and darkneſs, far exceeded any thing which happens in more temperate regions. See Iſa. xxiv. 10. Pſal. xviii.

The Hebrews, we ſhould recollect, were a people chiefly occupied with agriculture and paſturage, which were not diſdained by their patriarchs, kings, and prophets: but they were little addicted to commerce, and ſeparated from other nations by their laws and religion. They were, in the better days of their ſtate, ſtrangers in a great meaſure to the refinements of luxury. Hence ſprung their frequent alluſions to paſtoral life and to rural employments, inſtances of which continually recur. (See particularly Pſ. xxiii.) We alſo find figurative alluſions to the rites and ceremonies of their religion. Upon the whole, the face of their territory, the circumſtances of their climate, the manners of the people, and the auguſt ceremonies of their religion are conſtantly paſſing under different forms before us; and we ſhould duly recollect them when we are peruſing ſpecimens of their poetry, in order to our feeling its force and reliſhing its beauties. The happy influence of good government upon a people is exhibited by a fine compariſon in the laſt words of David, 2 Sam. xxiii. 3. "He that ruleth over men muſt be juſt, ruling in the fear of God; and he ſhall be as the light of the morning, when the ſun riſeth; even a morning without clouds; as the tender graſs ſpringing out of the earth, by clear ſhining after rain." The Pſalms and the prophetical writings are full of allegories and parables. But the poetical figure which, more than any other, elevates the ſtyle of ſcripture, and gives it a peculiar boldneſs and ſublimity, is proſopopœia or perſonification; and it may be obſerved, that no perſonifications employed by any poets are ſo magnificent and ſtriking as thoſe of the inſpired writers. The peſtilence is perſonified in Pſ. xci. 6. Habak. iii. 5. The waters, the mountains, &c. in Pſ. lxxvii. 16. cxiv. 4. Iſ. xliv. 23. 27. Habak. iii. 4. Job. xxviii. 22. Iſa. xiv. 9, &c. Jer. xlvii. 6. See PROSOPOPŒIA.

As to the ſeveral kinds of poetical compoſition that occur in the ſacred books, they are chiefly the didactic, elegiac, paſtoral, and lyric. Of the firſt of theſe, or the didactic, the book of Proverbs is the principal inſtance (ſee PROVERBS); the book of Eccleſiaſtes, and ſome of the Pſalms, particularly the 119th, belong to the ſame claſs. Many very beautiful ſpecimens of elegiac poetry occur in ſcripture; ſuch as the lamentation of David over his friend Jonathan, ſeveral paſſages in the prophetical books, and ſeveral of David's Pſalms, particularly the 42d. But the moſt regular and perfect elegiac compoſition is that work entitled "The *Lamentations* of Jeremiah," which ſee. Of paſtoral poetry we have a peculiar exemplification in the Song of Solomon. (See CANTICLES.) Of lyric poetry, or that which is intended to be accompanied with muſic, the Old Teſtament is full. Beſides a great number of hymns and ſongs, ſcattered in the hiſtorical and prophetical books, ſuch as the ſong of Moſes, the ſong of Deborah, and others of a ſimilar kind, the whole book of *Pſalms*, (which ſee,) may be conſidered as a collection of ſacred odes. See ODE.

The moſt eminent of the ſacred poets are Job, David, and Iſaiah. The compoſitions of David are of the lyric kind: and he chiefly excels in the pleaſing, ſoft, and tender manner; and though in his Pſalms there are many lofty and ſublime paſſages, yet in ſtrength of deſcription he yields to Job; in ſublimity, to Iſaiah. For the characters of the other poetical writers, ſee JOB, ISAIAH, JEREMIAH, EZEKIEL, HOSEA, JOEL, MICAH, HABAKKUK, and NAHUM, as they are ſketched out by biſhop Lowth. (See their reſpective articles.) In the prophecies of Jonah and Daniel, there is no poetry. Lowth's "De Sacra Poeſi Hebræorum," or Gregory's tranſlation of this learned and highly intereſting work, entitled "Lectures on the Sacred Poetry of the Hebrews," in two vols. 8vo. 1786. For an abridged account of it, ſee Blair's Lectures, vol. iii.

HEBREW *Points* or *Vowels*, are uſually reckoned five, which are the ſame with ours, *viz. a, e, i, o, u*; but then each vowel is divided into two, a long and a breve, or ſhort; the ſound of the former is ſomewhat graver and longer, and that of the latter ſhorter and more acute. It muſt be added, that the two laſt vowels have quite different ſounds; different, we mean, in other reſpects beſides quantity and degree of elevation. To theſe 10 or 12 vowels muſt be added ſome others, called "ſemi-vowels," which are only ſlight motions ſerving to connect the conſonants, and make the tranſitions more eaſy from one to another. On the ſubject of Hebrew vowels, ſee POINTS. See alſo HEBREW *Language*.

HEBREWS, *Epiſtle to the*, a canonical book of the New Teſtament, bearing no writer's name, but generally aſcribed to the apoſtle Paul. Concerning the date of this epiſtle, and occaſion of writing it, ſee EPISTLE.

We ſhall here give a conciſe account of ſome queſtions that have been diſcuſſed among biblical critics concerning this epiſtle. The firſt queſtion relates to the perſons for whom it was deſigned. Sir Iſaac Newton thought that it was written to Jewiſh believers, who left Jeruſalem about the time when the war broke out, and went into Aſia; and therefore he dates it in the year 66, beyond, as others conceive, the life-time of St. Paul, the ſuppoſed author of it. Mr. Wetſtein conceived that it was addreſſed by Paul to the Jewiſh believers at Rome, ſoon after he had been releaſed from his confinement in that city. But this opinion is unſupported by ancient authority, and deſtitute, ſays Lardner, of all appearance of probability. The more probable opinion is that of Lightfoot, Whitby, Mill, Pearſon, L. Capellus, Beza, Hallet, Michaelis, &c. which is, that it was ſent by Paul to the believing Jews of Judea, who were perſecuted by their unbelieving countrymen, and thus tempted to apoſtatize from Chriſtianity, and to think that there was ſtrength in the arguments urged by the perſecutors in favour of Judaiſm; againſt both which dangers the apoſtle guards them. This opinion is adopted by Dr. Lardner, who alleges the following reaſons in ſupport of it. This was the opinion of the ancient Chriſtian writers, who received this epiſtle, ſuch as Clement of Alexandria, Jerom, Euthalius, Chryſoſtom, Theodoret, Theophylact, &c. Beſides, many things occur in this epiſtle that rendered it peculiarly ſuitable to the believers in Judea. To the objections urged by Wall, Wetſtein, and others, againſt this opinion, Lardner has ſatisfactorily replied. The next queſtion pertaining to this epiſtle concerns the language in which it was written. On this queſtion there have been two principal opinions; one, that it was written in Greek, and the other, that it was originally written in Hebrew, and tranſlated into Greek. The former opinion has been very generally adopted by modern authors, among whom we may reckon J. A. Fabricius, Beauſobre, Capellus, Baſnage, Mill, Wetſtein, Lardner, &c. One argument particularly urged, both by Spanheim and Wetſtein, is taken from the Greek paronomaſias that occur in this epiſtle, or the frequent concurrence of Greek words of like ſound; and this argument, ſays Lardner, ſeems not eaſy to be anſwered. Another argument, called the moſt ſpecious by Michaelis, is founded on the word διαθηκη, as uſed in ch. ix. 16, 17.; which word admits of two ſenſes, and may denote either "covenant" or "teſtament;" but in the paſſage now cited it neceſſarily ſignifies teſtament; and

and this application could not have taken place in Hebrew, becauſe בריח, *berith*, the correſponding Hebrew word, does not admit of this ſenſe, and could only have taken place in the Greek, in which διαθηκη admits of a twofold meaning; conſequently the epiſtle was written in Greek. Again, the Hebrew name Μελχισεδεκ is interpreted, Heb. vii. 2. by the Greek words Βασιλευς δικαιοσυνης, and the Hebrew word Σαλημ by ειρηνη, which interpretation would have been ſuperfluous if the epiſtle had been written in Hebrew. Moreover, it is ſaid, that if the epiſtle to the Hebrews was written originally in Hebrew, it is very extraordinary that the original ſo ſuddenly diſappeared; that no eccleſiaſtical writer, even of the third or fourth century, ever ſaw a copy of it; and what is the reaſon, it is aſked, that the Nazarites and the Ebionites, who made uſe of the Hebrew goſpel of St. Matthew, are not mentioned, either by Jerom or Epiphanius, as having had a copy of the Hebrew epiſtle to the Hebrews; and why did the author of the Syriac verſion tranſlate this epiſtle from the Greek, if its original was Hebrew? It is alſo urged, that the quotations in this epiſtle from the Old Teſtament are made in the words of the Septuagint; and that this epiſtle is more free from Hebraiſms than moſt other books of the New Teſtament, which would hardly have been the caſe if it had been a tranſlation of a Hebrew original. Again, the epiſtle to the Hebrews contains many allegorical interpretations, ſuch as were in uſe among the Helleniſt Jews, and are found in the writings of Philo; whereas allegories of this kind were not adopted by the rabbins, who wrote in Hebrew, the Hebrew language being too pure to admit of them. Beſides, the quotation made in ch. i. 7. ὁ ποιων τους αγγελους αὐτου πνευματα, cannot be expreſſed in Hebrew. Again, the word "anchor" occurs, ch. vi. 19. a term which is hardly to be expected in a Hebrew work, as the Jews were not a ſeafaring nation; and the word δεχεσθωσαν, ch. x. 33. has a manifeſt alluſion to Greek cuſtoms, and the notion conveyed by it cannot be expreſſed in Hebrew, becauſe theatres were not permitted among the Jews. Theſe arguments are fairly ſtated by Michaelis, though, as he has adopted the other opinion, he has endeavoured to obviate and refute them. The opinion that this epiſtle was originally written in the Hebrew language, and tranſlated into Greek, has been maintained by ſome ancient Chriſtian writers, among whom have been enumerated Clement of Alexandria, Jerom, and as ſome have ſaid, though probably without ſufficient authority, Origen. Among the moderns, Michaelis is a ſtrenuous advocate for this opinion. He premiſes an obſervation that the term Hebrew thus applied, may denote either, 1. The language in which the greateſt part of the Old Teſtament was written, and which we call Hebrew, which was not a living language when the New Teſtament was written, though the Jews uſed it as the language of prayer, both in Paleſtine and in the Eaſtern Aſia; and it was underſtood by every man of education; or, 2. Chaldee, *i. e.* the Aramæan dialect, ſpoken in Babylon or Aſſyria, which was the language ſpoken by the Jews of Jeruſalem and Judea in the time of Chriſt, as the Jews of Galilee ſpoke Syriac, another Aramæan dialect, though very corruptly. Michaelis, in his diſquiſition on this ſubject, takes the word Hebrew, in its moſt extenſive ſenſe, as including both Syriac and Chaldee, as well as that which is commonly called Hebrew. The firſt argument he alleges in favour of his opinion, that this epiſtle was written in Hebrew is, that it was written for the uſe of the Hebrews, or Jewiſh Chriſtians in Jeruſalem. But ſome have ſet aſide this argument by alleging that Greek was the native language of the Jews of Jeruſalem; and Lardner argues, that Greek, if not the native language of the Jews, as Voſſius thought, was at leaſt underſtood by many of them. Another argument is deduced from the Greek ſtyle of this epiſtle, which, it is ſaid, cannot be St. Paul's original; for his manner of writing Greek is totally different, whether we regard the choice of ſingle words, the mode of connecting them, or the conſtruction and rotundity of the periods. Carpzovius, however, after ſome conceſſions, contends that the Greek epiſtle to the Hebrews was written by St. Paul, and that its ſuperiority to St. Paul's other epiſtles aroſe from the circumſtance, that the apoſtle had reſolved to exhibit a ſpecimen of fine writing, and to ſhew how well he was able to write Greek whenever he choſe it. He has alſo collected, in his "Prolegomena" to this epiſtle, expreſſions, which, in his opinion, betray the ſtyle of St. Paul; Heb. ix. 14. compared with 1 Theſſ. i. 9. Heb. iv. 16. compared with Epheſ. iii. 12. It has likewiſe been alleged, that long parentheſes occur in the epiſtle to the Hebrews, as well as in the epiſtles of St. Paul; but this, ſays Michaelis, is no proof that the Greek is St. Paul's original, for parentheſes are commonly retained in a tranſlation. If the epiſtle to the Hebrews, ſays this writer, was written originally in Greek, it was not written by St. Paul, in which caſe we have no ground for pronouncing it canonical. On the other hand, if St. Paul was the author, the Greek can only be a tranſlation, and the original muſt have been Hebrew. A new argument adduced by Michaelis in favour of his opinion is, that the quotations from the Septuagint, which occur in the epiſtle to the Hebrews, were made by a tranſlator, and not by the author; which, he ſays, appears from this circumſtance, that theſe quotations are ſometimes foreign to the purpoſe for which they were introduced, whereas the ſame paſſages, as worded in the Hebrew, are exactly in point. If in ſuch places the author himſelf had quoted the Old Teſtament in Greek, he would not have uſed the words of the Septuagint, but would have given his own Greek tranſlation of the Hebrew, as other writers of the New Teſtament have ſometimes done, eſpecially St. Paul. One example of this kind occurs in Heb. xi. 21. cited from Gen. xlvii. 31. Another inſtance is Pſ. civ. 4. quoted in Heb. i. 7. Moreover, Pſ. cx. 4. is often quoted and explained in the epiſtle to the Hebrews. Further, there are ſeveral paſſages in this epiſtle which, as worded in the Greek, appear to be inaccurate; but as ſoon as they are repreſented in the Hebrew we perceive that the inaccuracy is only in the tranſlation, Ch. iii. 3, 4. vi. 19. ix. 4. See alſo ch. ix. 11. If the epiſtle to the Hebrews was written in Greek, and conſequently the words quoted from the LXX were quoted by the author himſelf, it is very extraordinary that in the 11th chapter he ſhould have omitted to have mentioned in v. 4, 5. between Abel and Enoch, the name of Enoch, concerning whom language is uſed, Gen. iv. 26. which is ſo obviouſly to the writer's purpoſe. On the other hand, if we aſſume a Hebrew original of this epiſtle, the cauſe of this omiſſion is eaſily aſſigned; for the Hebrew text in Gen. iv. 26. at leaſt in the copies now extant, expreſſes a different meaning from the text of the Septuagint. In anſwer to this argument, however, it may be ſaid, that the author of the epiſtle conſulted the Hebrew text; and finding that the Greek differed from it, omitted the quotation. Of thoſe ancient Chriſtian writers who were of opinion that the epiſtle to the Hebrews was written in the Hebrew language, ſome of them maintained that it was tranſlated into Greek by Luke, or by Clement of Rome. Admitting the opinion, that it is only a tranſlation, Michaelis thinks that it proceeded from a perſon who was not infallible, and who was conſequently expoſed to the danger of miſtaking the ſenſe of his author. It muſt be allowed, however, by every one who underſtands

Greek, that the tranſlator, whoever he was, executed his taſk with ability; for, in general, his language is perſpicuous, his ſentences are well arranged, and the epiſtle is more eaſy to be underſtood than any of thoſe which were written by St. Paul. There are nevertheleſs inaccuracies; *e. g.* the word αιωνας, ch. i. 2.; μη πολι παρεξελυμεν, ch. ii. 1.; χαριτι θεου, ch. ii. 9.; ὁ καλασκευασας αυτον for בנן in the original, which ſhould have been ὁ υἱος αυτε, ch. v. 13. harſh and obſcure; ch. vi. 4. ch. vi. 19, 20. ch. vii. 14. ch. ix. 14—17. ch. ix. 19. ch. x. 1. ch. xi. 35. ch. xii 15. ch. xii. 18. ch. xii. 25. ch. xiii. 9. ch. xiii. 15. As to the Greek ſtyle of this epiſtle, it is obſerved to be different from that of every other book in the New Teſtament. It is likewiſe ſuperior to that of every other book, if we except the ſpeeches of St. Paul, recorded in Acts, xvii. 22—31. xxiv. 10—21. xxvi. 1—21. But though the language of theſe ſpeeches is equally good and fluent with that of the epiſtle to the Hebrews, it is ſtill of a very different kind.

Another inquiry relating to this epiſtle reſpects the author of it. Many of the ancients aſcribe it to the apoſtle Paul. Ignatius and Polycarp, in the beginning of the ſecond century, allude to this epiſtle; but the earlieſt writer, who expreſsly and frequently cites it as St. Paul's, is Clement of Alexandria, about the year 194. It is alſo received and quoted as Paul's by Origen, about 230; and by the manner in which this learned father cites it, it is evident that many churches and writers, who were ancient with reſpect to him, had one common tradition, that St. Paul was author of the epiſtle to the Hebrews. Dr. Lardner enumerates the Greek fathers and later Greek writers, who concurred not only in receiving this epiſtle as genuine, but in aſcribing it to St. Paul. Euſebius, biſhop of Cæſarea, in particular, about A.D. 315, often quotes it as St. Paul's, and as ſacred ſcripture. With regard to the Latin writers, though it was not expreſsly quoted as Paul's by any of them in the three firſt centuries, it was received as his by many of them in the fourth, fifth, and following centuries. Moreover, there is nothing in the epiſtle itſelf that renders it impoſſible or unlikely to be his. For it appears to have been written before the deſtruction of Jeruſalem, as was of old obſerved by Chryſoſtom and Theodoret, and as has been argued by many modern writers; and this is agreeable to paſſages that occur in the epiſtle itſelf, *e. g.* ch. viii. 4. ch. xiii. 10. and alſo to the ſcope of the author's reaſoning. There are alſo ſeveral exhortations in this epiſtle, that much reſemble ſome in the acknowledged epiſtles of St. Paul; *e. g.* Heb. xii. 3. compared with Gal. vi. 9. 2 Theſſ. iii. 13. Eph. iii. 13. —Heb. xii. 14. compared with Rom. xii. 18.—Heb. xiii. 1., &c. compared with Eph. v 2, 3, 4—Heb. xiii. 16. compared with Philip. iv. 18. See alſo Acts, ii. 42. Rom. xv. 26. 2 Cor. viii. 24. ch. ix. 13. Beſides, there are ſome inſtances of agreement in the ſtyle or phraſes of the epiſtle to the Hebrews, and the acknowledged epiſtles of St. Paul. Heb. ii. 4. compared with Rom. xv. 19 2 Cor. xii. 12. 2 Theſſ. ii. 9.—Heb. ii. 14. compared with 2 Tim. i. 10. 1 Cor. xv. 26—Heb. iii. 1. compared with Philip. iii. 14. 2 Tim. i. 9.—Heb. v. 12. compared with 1 Cor. iii. 2.—Heb. viii. 1. Eph. i. 21.—Heb. viii. 6. ix. 15. xii 24. Gal. iii. 19, 20. 1 Tim. ii. 5.—Heb. viii. 5. x. 1. Col. ii. 17.—Heb. x. 33. 1 Cor. iv. 9. Further, St. Paul often alludes, in his acknowledged epiſtles, to the exerciſes and games which were then very reputable and frequent in Greece and in other parts of the Roman empire. There are alſo divers alluſions in this epiſtle, which have alſo great elegance. Ch. vi. 18. xii. 1, 2, 3, 12. ch. xii. 4—ch. xiii. 9. Eph. iv. 14.—Heb. xiii. 10. 1 Cor. ix. 13. x. 18.—Heb. xiii. 20, 21. compared with Rom. xv. 33. xvi. 20. Philip. iv. 9. 1 Theſſ. v. 23. 2 Cor. xiii. 11. Further, the concluſion of this epiſtle has a remarkable agreement with the concluſion of St. Paul's epiſtles in ſeveral reſpects. Ch. xiii. 18. Rom. xx. 30. Eph. vi. 18, 19. Col. iv. 3. 1 Theſſ. v. 25. 2 Theſſ. iii. 1.—Ch. xii. 18. 22. compared with Acts, xxiv. 16.—Ch. xiii. 20, 21. compared with Rom. xv. 30—33. Eph. vi. 19—23. 1 Theſſ. v. 23. 2 Theſſ. iii. 16.—Ch. xiii. 24. compared with Rom. xvi. 1 Cor. xvi. 19—21. 2 Cor. xiii. 13. Philip. iv. 21, 22.—Ch. xiii. 25. compared with 2 Theſſ. iii. 18. Col. iv. 18. 1 Tim. vi. 21. Eph. vi. 24. 2 Tim. iv. 22. Titus, iii. 15. Moreover, the circumſtances of the epiſtle lead us to the apoſtle Paul. Ch. xiii. 24. compared with Acts, xxviii.—Ch. xiii. 19. compared with Philem. v. 22.—Ch. xiii. 23. compared with Philip. ii. 19. 1 Tim. i. 2. 2 Tim. i. 2. 2 Cor. i. 1. Col. i. 1. 1 Theſſ. iii. 2. Titus, i. 4. 2 Cor. ii. 13. All the conſiderations above recited, and ſtated more at large by Dr. Lardner, make out an argument, which, added to the teſtimony of many ancient writers, may warrant our concluding that the apoſtle Paul is the writer of this epiſtle. One of the chief objections againſt this opinion is the ſuperior elegance of this epiſtle compared with that of St. Paul's other writings. Hence Grotius and Le Clerc conclude, that it was not written by this apoſtle. To obviate this objection ſome have ſuppoſed that St. Paul was aſſiſted in compoſing it. The ſentiments, ſays Origen, are the apoſtle's, but the language and compoſition are thoſe of another perſon, who committed to writing the apoſtle's ſenſe, and as it were reduced into commentaries the things ſpoken by his maſter. Dr. Lardner conjectures, that St. Paul dictated the epiſtle in Hebrew, and another, who was a great maſter of the Greek language, immediately wrote down the apoſtle's ſentiments in his own elegant Greek. The ancients, beſides Paul, have mentioned Barnabas, Luke, and Clement, as writers or tranſlators of this epiſtle. But there is an obvious difference between the ſtyle of this epiſtle and that of theſe other writers. Another objection that has been repeatedly urged againſt aſcribing this epiſtle to St. Paul is the omiſſion of his name, which occurs in all his thirteen epiſtles. The elegance of the ſtyle, and the want of a name and inſcription, which are the two great objections againſt this being a genuine epiſtle of the apoſtle, ſays Lardner, are both owing to ſome particular circumſtances of the writer, and of the people to whom it was ſent. The people to whom it was ſent are plainly Jews in Judea; and the writer, very probably, is Paul, whoſe circumſtances, at the breaking up of his confinement at Rome, and his ſetting out upon a new journey, might be attended with ſome peculiar embarraſſments; which obliged him to act differently from his uſual method. Michaelis is of opinion, that if there be any preponderance in the arguments on both ſides, which are nearly of equal weight, it is in favour of the opinion, that St. Paul was not the author; but he thinks it impoſſible abſolutely to decide upon this queſtion.

As to the time and place of writing this epiſtle, it ſeems moſt probable that it was written at Rome or in Italy, ſoon after Paul had been releaſed from his confinement at Rome, in the beginning of the year 63.

Another queſtion, which Michaelis has particularly conſidered, regards the canonical authority of this epiſtle; or whether it ought to be received as an infallible rule of faith, and placed among the canonical books of the New Teſtament. The ancients entertained different opinions on this ſubject. Allowing the principle laid down by this biblical writer, that a canonical book of the New Teſtament is a book written by an apoſtle, it will follow, that if the apoſtle Paul was the writer of it, it is canonical; but otherwiſe, it is not canonical; for, however excellent its contents may be,

they

they alone will not oblige us to receive it as a work inſpired by the Deity. Lardner's Works, vol. vi. Michaelis' Introd. by Marſh, vol. iv.

HEBRIDES, or HEBUDES, in *Geography*, the name of ſeveral iſlands, ſituated in the Atlantic ocean, on the N.W. of Scotland, of which kingdom they conſtitute an integral part. In a geographical point, they are found to be included within 56° and 59° of N. latitude, and 5° and 8° of W. long. The various inſulated tracts of ground and cluſters of rock, thus detached from the main land, are calculated to amount to 300; and are ſaid to ſupport a population of 48,000 perſons. Theſe iſlands have at different times, and by different perſons, been denominated Ebridæ, Hebudæ, and Weſtern Iſlands; the latter of which is the moſt popular appellation. The names of the moſt conſiderable of theſe are Lewis and its ſmaller dependent iſlands belonging to the diſtrict of Roſſ-ſhire; Harris, North Uiſt, Benbecula, South Uiſt, Skye, Barra, Eigg, attached to the county of Inverneſs; Rum, Muck, Canna, Call, Tyrie, Mull, Liſmore, Staffa, Lering, Scarba, Colonſay, Oranſay, Jura, Iſla, Gigha, Cara, and ſome ſmaller, are ſubject to the civil juriſdiction of the ſhire of Argyle. Some other iſlands, ſituated in the frith of Clyde, are alſo reckoned among the Hebrides, and are within a few leagues of the coaſt of Scotland. Theſe, called the Interior Hebrides, are named Bute, Arran, Cumblays, (Greater and Leſſer) and Inchmarnock. As theſe inſulated diſtricts are commonly called the Weſtern Iſlands, we ſhall refer to that article, in a ſubſequent part of our work, for a hiſtory and deſcription of the whole. The reader, if deſirous of ample information on the ſubject, is referred to Johnſon's "Tour to the Weſtern Iſlands;" Boſwell's "Journal of a Tour to the Hebrides;" Martin's "Deſcription of the Weſtern Iſlands," a ſcarce and intereſting work; Buchanan's "Travels in the Weſtern Hebrides from 1782 to 1790;" Pennant's Tours in Scotland; Mrs. Murrays "Companion and uſeful Guide to the Beauties of Scotland." But more particularly to Chalmer's elaborate and intereſting work, entitled "Caledonia," and Sinclair's Statiſtical Account of Scotland.

HEBRIDES, or *Hebudes, New*, a group of iſlands in the South Pacific ocean, particularly ſurveyed, with regard to their ſituation and extent, by Capt. Cook in the year 1774. The northern iſlands of this Archipelago were firſt diſcovered by Quiros in 1606, and conſidered by him as part of the ſouthern continent, which at that time, and till very lately, was ſuppoſed to exiſt. They were next viſited by M. de Bougainville in 1768; who, beſides landing on the iſle of Lepers, did no more than diſcover that the land was not connected, but compoſed of iſlands, which he called the "Great Cyclades." Capt. Cook ſurveyed the whole, and diſcovered ſeveral new ones, which were not known before, and named them the New Hebrides. They are ſituated between S. lat. 14° 29′ and 20° 4′, and between E. long. 166° 41′ and 170° 21′, and extend 125 leagues in the direction of N.N.W. ½ W. and S.S.E. ½ E. The moſt northern iſland is that called by M. de Bougainville Peak of the Etoile; it is ſituated, according to his account, in S. lat. 14° 29′. E. long. 168° 9′, and N. by W. 8 leagues from Aurora. The next iſland, which lies fartheſt north, is that of Tierra del Eſpiritu Santo. (See TERRA *Auſtralis de l'Eſpiritu Santo*.) The next conſiderable iſland is that of *Mallicollo*; which ſee. St. Bartholomew lies between the S.E. end of Tierra del Eſpiritu Santo, and the north end of Mallicollo, and the diſtance between it and the latter is eight miles. This is the paſſage through which M. de Bougainville went; and its middle is in S. lat. 15° 48′. The iſle of Lepers lies between Eſpiritu Santo and Aurora iſland, 8 leagues from the former and three from the latter, in S. lat. 15° 22′ and nearly under the ſame meridian as the S.E. end of Mallicollo. It is of an egg-like figure, and 18 or 20 leagues in circuit. At the N.E. part there is anchorage half a mile from the land. Aurora, Whitſuntide, Ambrym, Paoom, and its neighbour Apee, Three-hills, and Sandwich iſlands, lie all nearly under the meridian of 167° 29′ or 30′ E., extending from the lat. of 14° 51′ 30″ to 17° 53′ 30″. Aurora lies N. by W. and S. by E., and in that direction is 11 leagues long, and hardly any where exceeds 2 or 2½ in breadth. It has a good height, and hilly ſurface, and is every where covered with wood, except where the natives have their dwellings and plantations. Whitſuntide iſle, 1½ league S. of Aurora, is of the ſame length, and lies in the direction of N. and S., but is ſomewhat broader than Aurora iſland. It is conſiderably high, and clothed with wood, except ſuch parts as ſeemed to be cultivated, which were pretty numerous. From the S. end of Whitſuntide iſland to the N. ſide of Ambrym is 2½ leagues. This iſland is about 17 leagues in circuit. Its ſhores are rather low, but the land riſes to a tolerably high mountain in the middle of the iſland, from which aſcended great columns of ſmoke; but Capt. Cook and his companions could not determine whether or not it was occaſioned by a volcano. It is ſuppoſed to be fertile and well inhabited. Paoom towers up to a great height, in the form of a round hay-ſtack; and the extent of this and an adjoining iſle (if there are two) cannot exceed three or four leagues in any direction; for the diſtance between Ainbrym and Apee is hardly five; and they lie in this ſpace, and E. from Port Sandwich, diſtant about 7 or 8 leagues. The iſland of Apee is not leſs than 20 leagues in circuit. Its longeſt direction is about 8 leagues N.W. and S.E; it is of a conſiderable height, and has a hilly ſurface, diverſified with woods and lawns, eſpecially the W. and S. parts. Shepherd's iſles are a group of ſmall ones, of unequal ſize, extending from the S.E. point of Apee about 5 leagues, in the direction of S.E. The iſland Three-hills lies S. 4 leagues from the coaſt of Apee, and S.E. ½ S. diſtant 17 leagues from Port Sandwich. There is W. by N., 5 miles from the W. point, a reef of rocks, on which the ſea continually breaks. Nine leagues, in the direction of S. from Three-hills lies Sandwich iſland. Two-hills, the Monument, and Montagu-iſlands lie to the E. of this line, and Hinchinbrook to the W., as alſo two or three ſmall iſles, which lie between it and Sandwich iſland, to which they are connected by breakers. Sandwich iſland is 25 leagues in circuit, its greateſt extent is ten leagues; and it lies in the direction of N.W. by W. and S.E. by E. The diſtance from the S. end of Mallicollo to the N.W. end of Sandwich iſland is 22 leagues in the direction of S.S.E. ½ E. In the ſame direction lie Erromango, Tanna, and Annatom. The firſt is 18 leagues from Sandwich iſland, and is 24 or 25 leagues in circuit. The middle of it lies in S. lat. 18° 54′. E. long. 169° 19′; and it is of a good height. *Tanna*, (which ſee,) lies ſix leagues from the S. ſide of Erromango, extending S.E. by S., and N.W. by N. about 8 leagues long in that direction, and every where about three or four leagues broad. The iſle of Immer lies in the direction of N. by E. ½ E., 4 leagues from Port Reſolution in Tanna; and the iſland of Erronan or Footoona Eaſt, in the ſame direction, diſtant 11 leagues. This, which is the moſt eaſtern iſland of all the Hebrides, appeared to be about five leagues in circuit, of conſiderable height, and flat at top. On the N.E. ſide is a little peak, ſeemingly diſjoined from the iſle, but thought to be connected by low land. Annatom, which is the ſouthernmoſt iſland, is ſituated in S. lat. 20° 3′. E. long. 170° 4′, and S. 30° E., 11 or 12 leagues from Port Reſolution. It is of

of a good height, with a hilly ſurface. For an account of the natives and productions of theſe iſlands, ſee MALLICOLLO and TANNA. Cook's Second Voyage, vol. ii.

HEBRON, in *Ancient Geography*, one of the moſt ancient cities of Paleſtine, built ſeven years before Tanis, the capital of Lower Egypt. (Numb. xiii. 22.) Some think, that it was founded by Arba, an ancient giant in Paleſtine, and hence called Kirjath-arba, or Arba's city, (Joſh. xiv. 15.) which name was afterwards changed into that of Hebron. Some have ſuppoſed that Caleb, having conquered this city, gave it the name of one of his ſons; whilſt others think that it was more ancient, and that Caleb gave to his ſon the name of this celebrated place. It was ſituated on an eminence, 20 miles S. of Jeruſalem, and 20 miles N. of Beerſheba. Abraham, Sarah, and Iſaac were buried near Hebron, in the cave of Machpelah. (Gen. xxiii. 7, 8, 9) This city was allotted to Judah; and aſſigned to Caleb for inheritance. (Joſh. xiv. 13.) Joſhua firſt took it and ſlew its king; (Joſh. x. 3. 23. 37.) but Caleb again conquered it. It was appointed for a dwelling of the prieſts, and a city of refuge. David, after the death of Saul, made it the ſeat of his kingdom. During the Babyloniſh captivity, the Edomites took it, and therefore Joſephus makes it a part of Edom. Hebron, or Hebroun, is ſtill in being; ſituated, ſays Volney, (Travels in Egypt, &c. vol. ii.) ſeven leagues to the S. of Bethlehem. The Arabs call this village, for ſuch is its preſent ſtate, "El-kalil," the *Well-beloved*, which is the epithet they uſually apply to Abraham, whoſe ſepulchral grotto they ſtill ſhow. It is ſeated at the foot of an eminence, on which are ſome miſerable ruins, the remains of an ancient caſtle. The adjacent country is an oblong hollow, five or ſix leagues in length, agreeably varied by rocky hillocks, groves of fir-trees, ſtunted oaks, and a few plantations of vines and olive trees. The grapes are not uſed for wine, which is prohibited by the Mahometans, but dried for raiſins. The peaſants cultivate cotton, which is ſpun by their wives, and ſold at Jeruſalem and Gaza. They have alſo ſome ſoap manufactories, the kali for which they purchaſe of the Bedouins, and a very ancient glaſs-houſe, the only one in Syria. In conſequence of its manufacture, Hebron is the moſt powerful village in this quarter, and is able to arm eight or nine hundred men, who adhere to the faction Kaigi, and are the perpetual enemies of the people of Bethlehem. This part of the country is in almoſt a continual ſtate of contention, depredation, and anarchy.

HEBRON, in *Geography*, a town of America, in Grafton county, New Hampſhire, containing 281 inhabitants.—Alſo, a town in Cumberland county, Maine, on the N. E. ſide of Little Androſcoggin, incorporated in 1792; 35 miles N. by W. of Portland.—Alſo, a poſt-town in Waſhington county, New York, containing 2528 inhabitants.—Alſo, a poſt-town in Tolland county, Connecticut, ſettled in 1704, and containing 2266 inhabitants, lying between Lebanon and Glaſtenbury, about 18 miles S. E. of Hartford.—Alſo, a Moravian ſettlement in Pennſylvania, begun in 1757, and ſituated 16 miles from Litiz, which is 70 miles northerly from Philadelphia.

HEBRUS, in *Ancient Geography*, the largeſt river of Thrace, riſing from mount Scomius, running into two channels, till it comes to Philippolis, where they unite. It empties itſelf at two mouths into the Ægean ſea, near Melanes Sinus, between Ænos, on the E. and Sala, on the W. It was ſuppoſed to roll its waters on golden ſands.

HEBUDA CHANNEL, in *Geography*, a name given by Pinkerton to that part of the Atlantic, which paſſes between Scotland and the extreme range of the Hebrides, or Hebudæ, from Barra to Lewis.

HECATE, in *Mythology*, a name of the infernal Diana, repreſented with all the characteriſtics of fury, holding inſtruments of terror in her hands, and graſping either cords, or ſwords, or ſerpents, or flaming torches. Under this character ſhe was exhibited with three bodies, and invoked in inchantments. Prof. Voſs, in the firſt volume of the "Nova Acta Soc. Lat. Jenenſis," endeavours to trace the origin of this deity, which he finds in Thrace, with a view of ſhewing the probable cauſe of the great variety of attributes beſtowed on her, and of reducing them to ſome ſort of unity. He adopts it as a principle, the truth of which is confirmed by the hiſtory of Hecate, whoſe image Pauſanias found ſtill in a ſimple ſhape at Ægina, that all deviations from the noble figure of man in the repreſentation of deities owe their origin to later myſtics and artiſts; and he conſiders it as ſingular, that the triple goddeſs has never been transformed into one multiplied by the ſacred numbers 7 or 9, or even by 100; that, though the name of Hecate is often uſed for Selene, Artemis, and Perſephone, we never find a triple Selene, or Perſephone, but often a three-headed Artemis mentioned; and that frequently by the ſide of Hecate, an Artemis is introduced, and likewiſe three-headed.

HECATEA, in *Botany*, ſo called by M. Aubert du Petit Thouars; whether with any reference to ἑκατη, a ſurname of Diana, or more directly to the epithet of Apollo ἑκατος, *long-darting*, and whether the appellation is juſtified by the wood ſerving for darts or arrows, we are altogether in the dark, not having that author's book before us, nor any further information reſpecting this genus, than what occurs in Willdenow, who is totally barren on its hiſtory.—Willd. Sp. Pl. v. 4. 513.—Claſs and order, *Monœcia Monadelphia*. Nat. Ord. *Euphorbiæ*.

Eſſ. Ch. Male, Calyx in five deep ſegments. Corolla none. Anthers three.

Female, Calyx in five deep ſegments. Corolla none. Style one. Stigmas three. Berry with three ſeeds.

1. H. *oppoſitifolia*. Willd.—Aubert Hiſt. Inſ. Afr. 28. t. 5.—"Leaves of the branches oppoſite, or three together; the floral ones alternate. Flowers in corymboſe panicles."—Native of Madagaſcar. A *tree* or *ſhrub*. *Leaves* two inches long, entire, veiny, abrupt, with two glands underneath at the baſe. *Flowers* panicled in a corymboſe manner, the corymbs three-forked, leafy.

2. H. *alternifolia*. Willd.—"Leaves alternate. Flowers in cluſters."—Native of the ſame country. It differs principally in having much larger, as well as alternate, *leaves*, and racemoſe *flowers*. Aubert as above quoted.

HECATOMB, HECATOMBE, in *Antiquity*, a ſacrifice of a hundred beaſts of the ſame kind, at a hundred altars, and performed by a hundred prieſts, or ſacrificers.

The word is formed of the Greek ἑκατομβη, which properly ſignifies a *ſumptuous*, or *magnificent ſacrifice*. Others derive it from the Greek ηκατον, *centum*, a *hundred*, and βους, *bos*, *bullock*, &c. On which footing the hecatomb ſhould be a ſacrifice of a hundred bullocks. Others derive the word from ἑκατον, and πους, *pes*, *foot*; and on that principle hold, that the hecatomb might conſiſt of only twenty-five four-footed beaſts. They add, that it was of no importance what kind of beaſts were choſen for victims, provided the quota of feet were but had.

Pythagoras is ſaid to have ſacrificed a hecatomb to the Muſes, of a hundred oxen, in joy and gratitude for his diſcovering the demonſtration of the 47th propoſition of the firſt book of Euclid; *viz.* that in a rectangled triangle, the ſquare of the hypothenuſe is equal to the ſquares of the other ſides.

For the origin of hecatombs, Strabo relates, that there were

were a hundred cities in Laconia; and that each city uſed to ſacrifice a bullock every year, for the common ſafety of the country; whence the inſtitution of the celebrated ſacrifice of a hundred victims, called hecatombs. Others refer the origin of hecatombs to a plague, with which the hundred cities of Peloponneſus were afflicted; for the removal of which, they jointly contributed to ſo ſplendid a ſacrifice.

Julius Capitolinus relates, that for a hecatomb they erected a hundred altars of turf, and on theſe ſacrificed a hundred ſheep, and a hundred hogs. He adds, that when the emperors offered ſacrifices of this kind, they ſacrificed a hundred lions, a hundred eagles, and a hundred other beaſts of the like kind.

HECATOMBÆON, in *Chronology*. See ECATOMBÆON.

HECATOMPHONIA, Ἑκατομφονια, an ancient ſacrifice among the Meſſenians; offered by ſuch as had ſlain a hundred enemies in battle.

The word comes from ἑκατον, a *hundred*, and φονευω, *to kill*.

HECATOMPOLIS, in *Ancient Geography*, an appellation given to the iſland of Crete, from its hundred cities. The ſame appellation was alſo given to Laconia.

HECATOMPYLOS, the metropolis of Parthia, and royal reſidence of Arſaces, ſituated at the ſprings of the Araxes. The ſame name was alſo given to Thebes in Egypt, from its hundred gates.

HECATONIA, in *Botany*, is derived from ἑκατον, *an hundred*, becauſe each flower produces about an hundred naked ſeeds. Loureir. Cochinch. 302.—Claſs and order, *Dodecandria Polygynia*. Nat. Ord. *Ranunculaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of five leaves; leaflets ovate, concave, coloured, reflexed. *Cor.* Petals five, ovate, ſtriated, ſmooth, ſpreading, about the length of the calyx. *Stam.* Filaments eighteen, thread-ſhaped, erect, unequal, ſhorter than the corolla, ſtanding round the baſe of an elongated receptacle; Anthers ovate, of two cells, upright. *Piſt.* Germens lenticular, about an hundred, placed round the ſame receptacle, which is raiſed in the ſhape of a column; ſtyle none; ſtigma a little prominent point at the top of each germen. *Peric.* none. *Seeds* lenticular, equal in number to the germens, affixed to the ſame cylindrical receptacle.

Eſſ. Ch. Calyx of five leaves, inferior. Petals five. Seeds numerous, naked.

1. H. *paluſtris*. Loureir.—"Leaves wedge-ſhaped, ſmooth. Germens collected into a cylinder."—Found in moiſt places near Canton in China.—An annual herb. *Stem* a foot high, nearly erect, thick, hollow, branched, ſmooth. *Leaves* ſtalked, ternate, wedge-ſhaped, cut, ſmooth *Flowers* ſmall, yellow, on nearly terminal, ſimple, ſolitary ſtalks.

2. H. *piloſa*. Ibid.—"Leaves lanceolate, hairy. Germens collected into a globe."—Plant hairy, and not quite ſo tall as the laſt. *Leaves* ternate, lanceolate, ſerrated, ſome of them cloven. *Flowers* yellow. *Fruit* globular, found with the laſt.

We know nothing of this genus but what we have taken from Loureiro. Dr. Smith has ſuggeſted that the plants are moſt probably ſpecies of *Ranunculus*, but this however cannot be determined with certainty, as the author ſays nothing of the peculiar nectary of that genus, with which ſurely he could not be totally unacquainted.

HECATONSTYLON, Ἑκατονστυλον, in the *Ancient Architecture*, a porch with a hundred columns. This deſignation was peculiar to the great porch of Pompey's theatre at Rome.

HECHINGEN, in *Geography*, a town of Swabia, the reſidence of a prince, which gives name to a branch of the family of Hohenzollern; 30 miles S. of Stuttgart.

HECK, among *Huſbandmen*, a rack, at which horſes are fed with hay.

It is alſo uſed as the name of an engine, wherewithal to take fiſh in the river Ouſe. A ſalmon heck is a grate for the catching that ſort of fiſh. See *Salmon*-FISHING.

Hence alſo *Heckagium*, or *Heccagium*, which occurs in ancient records for a rent paid the lord for the liberty to uſe ſuch engines.

HECK, in *Rural Economy*, a name frequently applied to a ſort of ſmall or half door, often employed in farm buildings.

HECKILA, in *Geography*, a town of Sweden in the province of Tavaſtland; 50 miles N. N. E. of Jamſio.

HECKLE, among *Hemp Dreſſers*. See HATCHEL.

HECKLING OF HEMP. See HEMP.

HECLA, or HEKLA, *Mount*, in *Geography*, a mountain ſituated in the ſouthern part of the iſland of Iceland, about four Britiſh miles from the ſea coaſt, above which it riſes to the height of about 5000 feet. The ſummit is covered with ſnow, except ſome ſpots where the heat predominates. On the higheſt point, where Fahrenheit's thermometer was at 24° in the air, it roſe to 153° when placed on the ground. The barometer ſtood at 22°.247. The craters of this volcanic mountain are numerous, but the eruptions rare; there having been only ten from the year 1104 to 1693, after which it remained quiet till 1766, when it emitted flames and lava, and when ſome of the ignited matter was thrown to the diſtance of 150 miles, and a circuit of between 60 or 70 miles laid waſte by the lava. In 1772 Hecla was viſited by Dr. Van Troil, a Swediſh gentleman, accompanied by Mr. Crow, ſir Joſeph Banks, Dr. Solander, and Dr. James Lind of Edinburgh. The lava, which they obſerved on their firſt landing, covered a tract of land 60 or 70 miles in extent, and appeared to have been in the higheſt ſtate of liquefaction. Having travelled 300, or 360 Engliſh miles, over an uninterrupted tract of lava, in their way to the top of the mountain, they had the pleaſure of being the firſt who had arrived at the ſummit of the mountain. On the ſummit they experienced at the ſame time a high degree of heat and cold, the thermometer being in different ſituations as above ſtated, and the wind became ſo violent, that they were ſometimes obliged to lie down for fear of being blown down the moſt dreadful precipices. The mountain ſeems to be compoſed, not of lava, but of ſand, grit, and aſhes; which are thrown up with the ſtones partly diſcoloured, and partly melted by the fire. Several ſorts of pumice ſtones were obſerved; among which was found one with ſome ſulphur. Some pumice was ſo much burnt, that it was as light as tow. Its form and colour were very fine, but ſo ſoft that it would not bear being removed from one place to another. The common lava was found in pieces of different ſizes; and likewiſe a quantity of black jaſper, burnt at the extremities, and reſembling trees with their branches. Among the ſtones thrown out by the volcano was obſerved ſome ſlate of a ſtrong red colour; and in one place the lava had taken the form of chimneys half broken down. In their deſcent they obſerved three openings; in one, every thing appeared as red as brick; in another, the lava had flowed in a ſtream about 50 yards broad, and in its progreſs had divided into three large branches. Further they perceived an opening, at the bottom of which was a mountain, in form of a ſugar-loaf, in the accumulation of which the fire ſeemed to have exhauſted itſelf. Moſt kinds of lava found in other volcanic countries are to be found about Hecla, and other Iceland volcanoes; as the dark, grey, perforated kind, reſembling

the Derbyſhire lead-ſtone; the Iceland agate, pumex vitreus, both the black and green, which ſome have thought to be the lapis Obſidianus, of which the ancients formed ſtatues. The lava is ſeldom found near the places of eruption, but looſe grit and aſhes, which compoſe the greateſt part of the Iceland mountains; but when it is grown cold, it aſſumes an arched form, the upper cruſt becoming hard and ſolid, and the melted matter under it remaining liquid. This forms large cavities, whoſe walls, bed, and roof are of lava, and in which great quantities of ſtalactite lava are found. In the iſland there are many caves of this kind, ſome of which, being large, are uſed by the inhabitants for ſheltering their cattle. The largeſt in the iſland is 5034 feet long, and from 50 to 54 broad, and between 34 and 36 h' ,h. See Iceland and Volcano.

HECQUET, Philip, in *Biography*, a celebrated French phyſician, was born at Abbeville, in Picardy, on the 11th of February, 1661. At the age of ſeventeen, after having received a domeſtic education under the eyes of pious parents, he went to Paris, where he ſtudied philoſophy and theology; to which laſt ſcience he retained an attachment, which greatly influenced his character and writings. By the perſuaſion of his uncle, however, he ſtudied medicine for two years, and in 16'4 went to Rheims, where he took his degree of M. D., and then returned to Abbeville to commence the practice of his profeſſion. But his deſire for knowledge induced him to return and ſettle in the metropolis; which, not being a member of the faculty there, he was about to quit in deſpair, when he was made phyſician to the religious foundation of Port-Royal, in 1688. He entered into all the auſterities of the place, and devoted himſelf ardently to attending the poor; and by exceſs and over-exertion in theſe reſpects he almoſt deſtroyed his health and conſtitution, ſo that his friends prevailed upon him to quit Port-Royal in 1693. In the year following, he was entered of the faculty at Paris, and in 1697 again received the doctor's cap from that more honourable faculty. He roſe to high reputation, both as a practitioner and teacher of medicine, which was probably favoured rather than impeded by the religious ſeverity of his manners. He was a declared enemy to all luxury of the table, and a patron of abſtinence and vegetable diet. His fondneſs for the uſe of the lancet and diluents was expoſed by Le Sage, in his character of *Sangrado:* yet he was much in faſhion, eſpecially among thoſe of the Janſeniſt party. He refuſed his aſſiſtance to no one, however, while his health allowed him; but he always attended the poor moſt readily, to whom his door was at all times open. In 1710, he was choſen phyſician to the hoſpital of La Charité, the duty of which he performed with all the zeal of principle, carrying his exertions and attention to the poor objects of his care beyond his ſtrength. In 1712 he was elected dean of the faculty, in which office he introduced a new code of medicines, or pharmacopœia. About the end of the year 1726, infirmities multiplied upon him, and he ſuffered an almoſt total loſs of power in the legs and right arm; upon which he determined to quit public life: and among the various offers of accommodation, and invitations which he received, he at length acceded to that of the Carmelite nuns, in the ſuburb of St. Jacques, to whom he had acted as phyſician upwards of thirty years. He there occupied a ſmall apartment, continuing the auſterities of his regimen with great rigour. Even in this retreat, he did not abandon the duties of his profeſſion; for ſtill his door was never ſhut againſt thoſe who wiſhed to conſult him, particularly the poor, of whom he was the friend and father. At whatever hour, or whatever might be his occupation, they were ſure of a kind reception; and when he knew their inability to purchaſe the medicines, or to purſue the regimen which he recommended, he generouſly furniſhed them with the means. He died in April 1737, at the age of 76, and was buried in the church of the Carmelites, where his tomb is diſtinguiſhed by a Latin epitaph, compoſed by Rollin.

Hecquet was a man of great reading, and a voluminous writer, a great advocate of the principles of the mechanical ſchool, and adverſe to the uſe of chemical medicines; he entered warmly into controverſy upon theſe ſubjects, and exhibited much falſe reaſoning in his works; and in practice he allowed obſervation to be clouded and falſified by hypotheſis. It is unneceſſary to copy the titles of works no longer read; but it ſhould be mentioned, to the author's credit, that, although ſo much attached to the Janſeniſts, he wrote againſt the fanatics, who exhibited their convulſions in the cemetery of St. Medard, and proved that there was nothing preternatural in their exhibitions. See Eloy. Dict. Hiſt. Gen. Biog.

HECTIC Fever, in *Medicine*, a ſlow, and irregularly remittent fever, commonly accompanying ſome local diſeaſe, and eſpecially a ſuppuration or ulceration of ſome part of the body, either internal or external.

The word is derived from the Greek, *hexis*, ἕξις, the *habit of body*, whence *hectica*, ἑκτικὴ, or *hectic-fever*, ſignifies an habitual or *conſtitutional fever;* becauſe it was believed by the ancients that the whole habit was diſeaſed in this fever, which they attributed to a conſtant preternatural degree of heat, generated and inherent, as it were, in the ſolids of the body. The hectic has received various other denominations from different authors; ſuch as *febris lenta*, or ſlow fever; *febricula*, or little fever; ſuppurative fever, &c. The Greek phyſicians, however, did not conſider the hectica as always a ſecondary complaint, depending merely on internal ſuppuration, or any local defect; but alſo as ariſing from a failure of ſtrength in old age, from an exhauſted ſtate of conſtitution, occaſioned by fatigue, long faſting, anxiety, or loſs of ſleep; and ſometimes a conſequence of *cauſus*, or other fevers. Actuarius particularly diſtinguiſhes the ſecondary ſpecies of hectic, connected with internal inflammation, ſuppuration, and ſcirrhus. (Med. lib. ii. cap. 1. See alſo Galen, de Maraſmo, et de Different. Pulſ. cap. 10. Paulus Ægineta, lib. ii. cap. 32, &c.) Several modern writers have likewiſe viewed the ſubject in a ſimilar light; of whom we may mention Etmuller (Opera Omnia, tom. ii. part 1.), Sauvages (Noſol. Method. claſs ii. gen. 5.), and Dr. Willan (Reports on the Diſeaſes of London); as well as Hoffman, Sydenham, and other writers of authority.

The hectic fever, under all its modifications, is characterized by the recurrence of a train of febrile ſymptoms every twenty-four hours, or ſometimes every twelve hours, with a remiſſion, rather than a complete intermiſſion, of thoſe ſymptoms in the intervals. Dr. Cullen, indeed, has affirmed, that there are two exacerbations every day. The firſt of theſe, he remarks, occurs about noon, ſometimes a little ſooner or later; and a ſlight remiſſion of it happens about five in the afternoon. This laſt, he ſays, is ſoon ſucceeded by another exacerbation, which gradually increaſes till after midnight; but after two o'clock of the morning a remiſſion takes place, which becomes more and more conſiderable as the morning advances. The exacerbations are frequently attended with ſome degree of chilline's and ſhivering; or, at leaſt, the patient is exceedingly ſenſible to any coolneſs of the air, ſeeks external heat, and often complains of a ſenſe of cold, when to the thermometer his ſkin is preternaturally warm. After the chilline's goes off, a general increaſe of heat ſucceeds; and the face, which is commonly pale,

pale, becomes of a florid red, the redneſs generally appearing in a circumſcribed ſpot, however, on one or both cheeks. Before the remiſſion of the morning takes place, a ſweat generally breaks out; and theſe ſweats continue to recur, and become more and more profuſe, through the whole courſe of the diſeaſe.

Of the two daily exacerbations, of which Dr. Cullen ſpeaks, "that of the evening," he obſerves, "is always the moſt conſiderable." It muſt be remarked, however, that other phyſicians have not generally witneſſed this double exacerbation, and uſually deſcribe the hectic as conſiſting only of one, and that an evening exacerbation, terminating in the morning ſweats.

It may be obſerved, that the progreſs of the paroxyſm above deſcribed reſembles in ſeveral reſpects the paroxyſm of intermittent fever, or common ague; and in popular language it is in fact uſually denominated an intermittent fever. But in the recurrence and the phenomena of theſe exacerbations, there is nothing approaching to the regularity and uniformity of the true intermittent, as Dr. Heberden has well pointed out. "The hectic fever," ſays that accurate obſerver, "will return with great exactneſs, like a quotidian, or tertian, or quartan, for two, or perhaps three fits; but I do not remember ever to have known it keep the ſame period for four fits together. The fit will now and then keep off for ten or twelve days; and at other times, eſpecially when the patient is very ill, it will return ſo frequently on the ſame day, that the chilline ſs of a new fit will follow immediately the ſweat of the former. It is not unuſual to have many threatenings of a ſhivering in the ſame day."

The ſeries of ſymptoms are not leſs irregular in their variety and ſucceſſion, than the whole exacerbation in its periods of return. "The chilline ſs of hectic fever," ſays the ſame author, "is ſometimes ſucceeded by heat, and ſometimes immediately by a ſweat, without any intermediate ſtate of heat; and the heat will ſometimes come on without any remarkable previous chilline ſs, and the chilline ſs has been obſerved to go off without being followed either by heat or ſweat. The duration of theſe ſtages is ſeldom the ſame for three fits together." "The hectic patient is little or not at all relieved by the coming on of the ſweat; but is often as anxious and reſtleſs in the ſweat, as in the chilline ſs and heat. When the ſweat is over, the fever will ſometimes continue, and in the middle of the fever the chilline ſs will return, which is a moſt certain mark of this fever: almoſt all others begin with a chilline ſs; but the return of this, ſo as to laſt half an hour or longer, while the fever is ſtrong upon the patient, is what I never ſaw, except only in this fever." (Heberden, in Medical Tranſact. of the College, vol. ii. art. 1. Alſo in his Commentar. de Morbor. Hiſt. et Curat. cap. 39.)

The urine is frequently clear in the early parts of the exacerbations, and depoſits a copious pink ſediment at the decline of it, and during the interval, as in the true intermittent. But there are all ſorts of irregularities in this reſpect in the hectic. Sometimes it will be equally clear or equally turbid in both ſtages; or even turbid in the fits and clear in the intervals; and ſometimes almoſt from the firſt appearance of the diſeaſe the urine is high coloured, and depoſits a copious branny red ſediment, which ſeldom falls cloſe to the bottom of the veſſel.

In the hectic, the appetite for food is generally leſs impaired than in any other kind of fever. The thirſt is ſeldom very conſiderable; the mouth is commonly moiſt; and as the diſeaſe advances, the tongue becomes free from all fur, appears preternaturally clean, and, in the advanced ſtages of the diſeaſe, it appears, as well as the throat, to be ſomewhat inflamed, and more or leſs of an aphthous ulceration takes place. For ſome time in the courſe of the diſeaſe the bowels are bound: but in the advanced ſtages of it, a diarrhœa almoſt always comes on, and continues to recur frequently, alternating in ſome meaſure with the ſweatings mentioned above.

Hectic fever is always attended with debility, which gradually increaſes during its progreſs, and emaciation takes place to a greater extent, than in almoſt any other diſeaſe. Towards the end, the feet are often affected with œdematous ſwellings. The exacerbations of the fever are ſeldom attended with any head-ache, and ſcarcely ever with delirium; the ſenſes and judgment commonly remaining entire to the very cloſe of the diſeaſe.

The *diagnoſis* of this fever, as it is commonly ſymptomatic of ſome internal or external diſeaſe, does not conſiſt ſo much in diſtinguiſhing it from the true intermittent or remittent fever, (from which the difference is very obvious from the hiſtory of the diſeaſe, as above detailed,) as in aſcertaining the ſeat and nature of the local affection by which it is excited. This is to be done, of courſe, by inveſtigating the derangement of the functions in particular organs, *e. g.*, the lungs, liver, glands, and other parts. Where the progreſs of the fever is inſidious, however, and the preſence of local diſeaſe is obſcure, an attention to the ſtate of the pulſe, as Dr. Heberden ſuggeſts, is one of the greateſt helps to detecting the degree of diſeaſe going on. "Gentle as the ſymptoms may ſeem," he ſays, "if the pulſe be quicker than ordinary, ſo as to have the artery beat at leaſt ninety times, and perhaps a hundred and twenty times in a minute, there will be the greateſt reaſon to be apprehenſive of the event. There is perhaps no diſorder of the body, in which the pulſe is of more uſe to guide our judgment, than in the complaint which has been deſcribed. And yet even here we muſt be upon our guard, and ought not to truſt entirely to it; for one in about twenty patients, with all the worſt ſigns of decay from ſome incurable cauſe, which irreſiſtably goes on to deſtroy his life, will ſhew not the leaſt degree of quickneſs, nor any other irregularity of the pulſe, to the day of his death." Loc. cit.

The cauſes of hectic fever have been the ſubject of conſiderable difference of opinion. The ancients conſidered it as often the conſequence of internal diſeaſe; and many moderns, among whom Dr. Cullen ſtands conſpicuous, deemed it in all caſes a ſecondary fever, and aſcribed it excluſively to the abſorption of *pus*. "I have never ſeen it in any caſe," that able phyſician obſerved, "when there was not evidently, or when I had not ground to ſuppoſe there was, a permanent purulency or ulceration in ſome external or internal part. Indeed it appears to me to be always the effect of an acrimony abſorbed from abſceſſes or ulcers, although it is not equally the effect of every ſort of acrimony; for the ſcorbutic and cancerous kinds often ſubſiſt long in the body without producing a hectic. What is the preciſe ſtate of the acrimony producing this I cannot determine, but it ſeems to be chiefly that of a *vitiated purulency*." (Firſt Lines, parag. 861.) In favour of this opinion the great majority of inſtances of hectic may undoubtedly be cited. The moſt numerous caſes are certainly connected with the ſuppuration of the lungs, in pulmonary conſumption: with cancerous, ſcrofulous, and other ſlow ulcerations and ſuppurations, in the glands of the ſurface and in the abdomen, with the progreſs of deep-ſeated abſceſſes in membranous and muſcular parts, as in the pſoas abſceſs, &c. But very many caſes are alſo recorded, and frequently obſerved, in which a variety of other cauſes have been connected with hectic, and which agree with each other in one common operation, as well as with thoſe ulcers and ſuppurating tumours, namely, in keeping

up a conſtant *irritation* in the ſyſtem. Dr. Gregory, the preſent profeſſor of medicine at Edinburgh, ſeems to be juſtified, therefore, in aſcribing hectic in general to ſome great local irritation. So far from a "*vitiated* purulency" being the chief cauſe of hectic, according to Dr. Cullen's hypotheſis, we have the authority of Dr. Heberden for ſtating that "this anomalous fever is never leſs dangerous, than when it belongs to a kindly ſuppuration, into which all the diſeaſed parts are melted down, and for which there is a proper outlet."

Among the varieties of hectic enumerated by Sauvages, few are referable to the preſence of ſuppuration. The Hectica *infantilis*, H. *chlorotica*, H. *à calculis*, H. *hydropum*, H. *cachectarum*, H. *verminoſa*, H. *noſtalgica*, all ariſe independently of any ſuppuration in the body, and ſeem to depend either upon ſome extraordinary irritation, corporeal and mental, or upon an increaſed debility and irritability of the habit, which render it too ſuſceptible of the operation of ordinary irritations. Dr. Willan has made ſome obſervations worthy of attention on this ſubject. After remarking, that he employs the *hectica* in the ſignification given to it by the Greek phyſicians, among whom it was not conſidered merely as a ſecondary complaint, depending on internal ſuppuration, or any local defect; but as ariſing from a failure of ſtrength in old age, from an exhauſted ſtate of conſtitution, occaſioned by fatigue, long faſting, anxiety, or loſs of ſleep, and ſometimes as a ſequel of *cauſos* or other fevers;—Dr. Willan ſtates, that "in infancy, childhood, youth, and old age, hectic takes place, without any local affection, from changes in the conſtitution, connected with the different ſtages of life." (Reports on the Diſeaſes of London, pref. x.) "A ſpecies of hectic," he obſerves in another place, "occurs in infants and children from conſtitutional circumſtances, without any apparent local affection. It is attended with a very quick pulſe; with heat and fluſhing during the paroxyſm; and throughout with an extreme degree of irritability and inquietude; ſometimes with loſs of appetite, ſometimes with a craving for ſtrong food; and an equal irregularity reſpecting the ſtate of the bowels. Theſe ſymptoms continue for a length of time, and occaſion a waſting, with loſs of ſtrength; they uſually precede a conſiderable increaſe of ſtature." (Reports, p. 19.) Again "in the liſt of periodical diſeaſes, the complaint termed hectica *adoleſcentium* frequently affects young perſons, during the period of their growth, after the age of puberty. It is characterized by febrile paroxyſms occurring every day, pain in the limbs, often with painful ſwellings in the joints, loſs of ſleep and appetite, and great emaciation. If a cough does not ſupervene, the patients recover in ten or twelve weeks." (loc. cit.)

Dr. Willan obſerves, moreover, that a ſimilar ſtate of diſorder is often produced in perſons of the middle age, when the conſtitutional vigour firſt appears to decline, not reſiſting as uſual the operation of cold, fatigue, and other occaſional cauſes of diſeaſe; and that this ſtate is moſtly accompanied with aphthous ulcerations of the tongue and fauces, and a large ſecretion of frothy phlegm. This he calls hectica *aphthoſa*, and has detailed its progreſs minutely. He concludes the hiſtory of it by obſerving, that, "after the tongue, fauces, &c. have been healed, the aphthous ulcerations return again, with internal heat, general uneaſineſs, and the ſame train of ſymptoms as at firſt. By frequent relapſes of this kind, the patient is often reduced to an extreme degree of debility and emaciation; and the whole duration of the complaint is from five to twelve weeks." Ibid. Pref.

For an account of the hectica *ſenilis*, or that form of the hectic which occurs in old age, Dr. Willan refers to Hoffmann; who, we find, ſpeaks of it under the denomination of *maraſmus ſenum*. "The hectic," he ſays, "which is common and fatal in old people, is called by the Greek term μαράσμος. The appetite fails, the ſtrength gradually decays, the body waſtes, and the bones appear like a ſkeleton covered with ſkin. The mouth is dry, the ſaliva viſcid, the ſkin cold, parched, and rigid; the internal parts are hot; the pulſe is hard and frequent; the ſleep ſcanty and unrefreſhing; there is ſome dyſpnæa, and the voice is hoarſe. Theſe ſymptoms gradually increaſe until the patient, in the courſe of five or ſix months, ſinks under them." (Hoffmann, Med. Ration. Syſt. tom. ii. ſect. ii. cap. xiii.)

Treatment of Hectic.—It muſt be obvious, from the preceding obſervations, that, ſince hectic fever is moſt commonly a ſecondary diſeaſe, and depends upon ſome local irritation or derangement of ſtructure, no one ſyſtem of treatment can be expected to cure it. The cure, indeed, under ſuch circumſtances, can only be effected by the removal of the primary diſeaſe. Therefore to deſcribe the method of cure for hectic, would be to give a general detail of the modes of treating conſumption, tabes meſenterica, ſcrofula, and other diſeaſes, in which a ſlow ſuppuration or ulceration is going on. The general indications, however, ſo far as relate to the alleviation of the febrile ſymptoms of heat, thirſt, languor, ſweating, diarrhœa, &c. are to withdraw every ſtimulus, which may add to the morbid irritation from the local diſeaſe; to leſſen the ſuſceptibility to ſtimuli; and to ſupport the ſtrength by the mildeſt nutriment; as well as to check the urgency of particular ſymptoms, which tend to reduce the powers of the conſtitution.

1. The abſtraction of ſtimuli is effected partly by diet and regimen, ſuch as has already been preſcribed under the head of CONSUMPTION; namely, by excluding all ſolid animal food, and vinous, ſpirituous, or fermented liquors, and confining the patient to a diet of milk, and vegetables; including whey, butter-milk, and the milk of various animals, the farinaceous ſubſtances, ſummer fruits, &c.; with aqueous liquors, as various infuſions of herbs, ptiſan, &c. rendered grateful by the juices of ſub-acid fruits, with ſugar. Exerciſe, performed without much muſcular exertion, and not carried to fatigue, eſpecially geſtation, ſailing, and ſwinging, may in many caſes be employed with advantage. (See EXERCISE.) The oppoſite irritations of cold and heat ſhould be carefully obviated; the former being guarded againſt by warm clothing, a warm apartment, and avoiding expoſure to the immediate influence of cold air; and the latter, which is generally troubleſome and prejudicial in the paroxyſm only, by a partial and temporary removal of the coverings of the patient, and by diminiſhing with caution the temperature of his apartment.

2. The ſuſceptibility to the impreſſion of irritations, is principally to be diminiſhed by medicines of the narcotic claſs, ſuch as opium, the extract of poppy, conium, (hemlock), hyoſcyamus (henbane), &c. It is probably by their operation in this manner, by giving relief to the feelings of the patient, and by rendering the whole of the involuntary organs of circulation, ſecretion, and excretion, leſs ſuſceptible of excitement, that the conium or cicuta eſpecially has contributed ſo extenſively to the relief and cure of glandular ulcerations. In this way opium is alſo exceedingly beneficial, in allaying inordinate actions of the bowels, in procuring ſleep, and in preventing the debilitating effects of purging and watching.

3. The neceſſity of ſupporting the ſtrength by the mildeſt forms of aliment, has already been inſiſted on above. The ſtrength is ſcarcely more depreſſed by the want of nutri-

ment, than by the uſe of that which is too heavy for the weakened powers of digeſtion, and which, while it fails to afford the requiſite nutrition, excites an additional febrile irritation in the ſyſtem.

4. The occaſional ſeverity of particular ſymptoms is to be reſtrained by medicines adapted to the circumſtances. Thus where a diarrhœa, as is not uncommon in hectic of ſome continuance, becomes violent, reducing the body by the frequency and quantity of the diſcharge from the bowels, the uſe of opiates, with or without the addition of cretaceous or aſtringent medicines, muſt be reſorted to; or, on the other hand, when the morning ſweats, which terminate the exacerbation, become profuſe and colliquative, the adminiſtration of the mineral acids, eſpecially the ſulphuric (or vitriolic) acid, diluted, will generally contribute to diminiſh the diſcharge. The ſweating and diarrhœa are very apt to alternate with each other, and the medicines which ſuſpend the one, are rather liable to induce the other.

Soon after the general introduction of the Peruvian bark into practice in this country, the ſimilarity of hectic to the intermittent fevers, and alſo ſome prevalent hypotheſis, that the bark "rendered ſuppuration more kindly," it was given copiouſly in the different modifications of hectic; but Dr. Heberden, while he affirms, that he never ſaw any material harm done by the bark in hectic, yet he acknowledges, that he had never ſeen any good from it. We believe that experience has now decided upon its rejection from the practice in hectic from ulceration, at leaſt from that connected with pulmonary conſumption; and the ſteel draught of Dr. Moſes Griffith has nearly met with the ſame fate. Theſe medicines, however, as well as the mineral acids, have been preſcribed with advantage in the hectica adoleſcentium, where there was little or no cough, and where the hectic ſeemed to originate from a general debility of habit, approaching to the chlorotic ſtate.

On the whole, perhaps, theſe few lines of Dr. Heberden contain the ſum of the practical precepts relative to hectic in general. "In moſt caſes, the principal, if not the ſole attention of the phyſician muſt be employed in relieving the ſymptoms, by tempering the heat, by preventing both coſtiveneſs and purging, by procuring ſleep, and by checking the ſweats; and if, at the ſame time, he endeavours to put the body into as good general health as may be, by air, exerciſe, and a proper courſe of mild diet, he can perhaps do nothing better, than to leave all the reſt to nature." (See Medical Tranſactions, vol. ii p. 12.)

HECTO, in the new *Meaſures* and *Weights* of France, ſignifies 100 times, when uſed as a prefix; thus hectometre ſignifies 100 metres, and hectogramme ſignifies 100 grammes; ſo hectolitre ſignifies 100 litres = 10 cubic metres; hectoſtere ſignifies 100 cubic metres, &c.

HECTOR, in *Geography*, a military townſhip in New York, on the E. ſide of Seneca lake, near the Sead.

Hector, in *Ancient Hiſtory*, the ſon of Priam and Hecuba, and the father of Aſtyanax, celebrated for the valour with which he defended the city of Troy againſt the Greeks. He was killed by Achilles, who dragged his body, faſtened to his chariot, thrice round the walls of Troy, and afterwards reſtored it to Priam for a large ranſom. See Troy.

HECUBA, in *Fabulous Hiſtory*, the ſecond wife of Priam, and mother of Hector and Paris, was, according to Homer, the daughter of Dymas, or as Virgil, following Euripides, ſays, of Ciſſeis, king of Thrace, and ſiſter of Theano, the prieſteſs of Apollo at Troy during the war. After the capture of Troy, ſhe attempted to revenge the death of her ſon Polydorus, and was ſtoned to death by the Greeks. Some ſay that ſhe became a ſlave to Ulyſſes, and that this prince left the unfortunate princeſs in the hands of her enemies, who cauſed her to be ſtoned. It is probable, however, that Ulyſſes himſelf was the cauſe of her death. Becauſe, it is ſaid, that upon his arrival in Sicily, he was ſo tormented with dreams, that in order to appeaſe the gods, he built a temple to Hecate, who preſided over dreams, and a chapel to Hecuba.

HED, in *Geography*, a town of Sweden, in Weſtmanland; 25 miles W. N. W. of Weſteraks.

HEDAGIUM, anciently ſignified a toll or cuſtom, paid at the hythe or wharf, &c. for landing merchandize, goods, &c.

The word is formed from *heda, a hythe, port*, or *wharf*. From ſuch toll or cuſtomary duty, exemptions were ſometimes granted by the ſovereign to particular perſons and ſocieties.

HEDDING, in *Geography*, a town of Denmark, in the iſland of Zealand; 32 miles S. S. W. of Copenhagen.

HEDE', a town of Sweden, in Harjedalen; 10 miles S E. of Langaſahantz.—Alſo, a town of Sweden, in the province of Weſt Gothland; 32 miles N. W. of Uddevalla.

Hede', a town of France, in the department of the I le and Vilaine, and chief place of a canton, in the diſtrict of Rennes. The place contains 685, and the canton 9494 inhabitants, on a territorty of 175 kiliometres, in 11 communes. N. lat. 48° 18'. W. long. 1° 43'.

HEDEMORA, a town of Sweden, in the province of Dalecarlia, and one of the principal towns of the kingdom, ſituated near a lake, well built and commercial. In this town is a large manufacture of gun-powder; 53 miles N. W. of Upſal. N. lat. 60° 13'. E. long. 15° 54'.

HEDEN, a town of Sweden, in Weſt Bothnia; 30 miles N. W. of Lulea.

HEDERA, in *Botany*, has been ſaid to owe its derivation to the word *hædus*, a kid, becauſe it was given to goats by the ancients, in order to make them have abundance of milk for the nouriſhment of their kids. It has alſo been ſpelled thus, *edera*, and then its origin is ſuppoſed to be from the word *edita*, either becauſe it [illegible] in *lofty* ſituations, or becauſe it lays waſte whatever it [illegible]heres to, and thus may be ſaid to *eat* it; for this plant is vulgarly ſuppoſed to appropriate to its own uſe the eſſential juices of ſuch trees as ſupport it. It is called [illegible] in Greek, from Ciſſos, a favourite of Bacchus, whom the poets fable to have been transformed into this plant, and hence it became ſacred to that god.—Linn. Gen. 111. Schreb. 155. Willd. Sp. Pl. v. 1. 1179. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 267. Ait. Hort. Kew. v. 1. 281. Juſſ. 214. Tournef. t. 384. Lamarck Dict. v. 3. 511. Illuſtr. t. 125. Gærtn. t. 26.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Hederaceæ*, Linn. *Caprifolia*, Juſſ.

Gen. Ch. *Cal.* Perianth very ſmall, five-toothed, encircling the germen. *Cor.* Petals five, oblong, broad at the baſe, ſpreading, their tops incurved. *Stam.* Filaments five, awl-ſhaped, erect, as long as the corolla; anthers cloven at the baſe, incumbent. *Piſt.* Germen turbinate, encircled by the receptacle; ſtyle ſimple, very ſhort; ſtigma ſimple. *Peric.* Berry globoſe, of one cell, (or, according to Gærtner, of five cells). *Seeds* five, large; on one ſide gibbous, on the other angular.

Eſſ. Ch. Calyx five-toothed. Petals five, dilated at the baſe. Berry with five ſeeds, encircled by the calyx.

Among the ſpecies of this well-known and ornamental genus, the *quinquefolia* has been referred by Juſſieu to *Vitis*, and we think with great propriety. *Hedera helix* is the only ſpecies indigenous to Great Britain.

1. *H. Helix.* Common Ivy. Linn. Sp. Pl. 292: Engl.

Bot. t. 1267.—"Leaves ovate and lobed."—"Every one is acquainted with the ivy, ſo common and ſo pictureſque upon old walls and the trunks of aged trees. Nor does it leſs commonly creep on the ground in dark woods, forming an evergreen carpet. It is the lateſt of all our flowering plants, bloſſoming in October and November, and ripening its berries in the ſpring. The whole plant partakes of a peculiar aromatic flavour. From the old ſtems, when bruiſed, a very fragrant reſin exudes."—*Stem* and *branches* long and flexible, creeping, attached cloſely to trees or walls by ſhort fibres; upper branches ſpreading, round and ſmooth. *Leaves* evergreen, dark, having white veins, upper ones ovate, lower ones five-lobed, all ſtanding on footſtalks. *Flowers* green, of many umbels, forming a corymbus. *Berry* globular, black, mealy within.

Mr. Curtis remarks, that when ivy trails on the ground its branches are ſmall and weak, its leaves divided into three lobes. Hence, this difference of appearance induced old botaniſts to ſeparate the plant in queſtion into two or three diſtinct ſpecies. In its variegated ſtate it ſometimes appears almoſt white, and may, perhaps, be the *Hedera alba*, or *pallentes Hederæ* of Virgil.

2. H. *pendula*. Swartz. Ind. Occ. v. 1. 512.—"Leaves ovato-lanceolate, entire. Umbels ſomewhat capitate. Stems very long, pendulous."—Native of high mountains in the weſt of Jamaica, flowering in May.—The *trunk* of this ſhrub is about ten or twelve feet high, having a ſmooth bark. *Branches* ſpreading, ſubdivided; leſſer ones erect. *Leaves* on long footſtalks, ſcattered, oppoſite, or ternate, very ſmooth and ſomewhat rigid. *Umbels* axillary, on long ſtalks, pale.

3. H. *nutans*. Swartz. Ind. Occ. v. 1. 514.—"Leaves elliptical, leathery. Umbels drooping, hemiſpherical. Stems erect."—Native of the Blue mountains in the ſouth of Jamaica, and gathered on their very ſummit.—It is nearly allied to *H. pendula*, but differs in its leaves; the *ſtems* alſo are ſhorter and nearly erect; and the *umbels* are ſmaller.—*Branches* round, furrowed, grey. *Leaves* on footſtalks about their own length, extremely ſmooth. *Petals* ovate, acute, reflexed, deciduous. *Filaments* inſerted into the baſe of the calyx.

4. *H. capitata*. Swartz. Ind. Occ. v. 1. 516. Smith. Ic. Pict. Rar. t. 4. (Aralia capitata; Jacq. Amer. 89. t. 61.)—Leaves elliptical, ſcattered. Cluſters compound, terminal, downy. Flowers capitate.—Native of mountains in the Caribbee Iſlands and Jamaica, where it flowers in February. It exiſted in the collection of the late marquis of Rockingham long before 1777, but whence that plant was procured is not known. It flowered for the firſt time in Europe in the ſtove of the late marchioneſs in the year 1787, from which period it has continued flowering annually, but as no ſeed has been produced it muſt be propagated by cuttings. This ſpecies was tranſferred from *Aralia* to *Hedera* by Dr. Smith, who has been followed by Swartz, and hence the latter was induced to refer *Aralia arborea* in like manner to the ſame genus. This plant is rendered extremely ornamental by its browniſh grey *bark*, aſcending *branches*, and innumerable *flowers* terminating each branch in doubly compound, pale, downy cluſters, which are white, and form denſe heads at the extremity of each ſtalk.

5. *H. arborea*. Swartz. Ind. Occ. v. 1. 518. (Aralia arborea; Linn. Sp. Pl. 392. Jacq. Amer. 89. Hedera arbor folio haſtato; Plum. Ic. 139. t. 148.)—Leaves elliptical, ſcattered. Cluſters ſimple, terminal, ſmooth. Flowers umbellate, with a ſimple, many-toothed involucrum.—Native of Jamaica, and other parts of the Weſt Indies, flowering in December. Jacquin ſays this is an inelegant tree, 15 feet high, with a diſagreeable ſmell. Its *leaves* greatly reſemble the laſt, but the infloreſcence eſſentially diſtinguiſhes it. The radiating, many-toothed involucrum under each of the little umbels is very peculiar.

6. *H. Sciodaphyllum*. Swartz. Ind. Occ. v. 1. 519. Brown Jam. 190. t. 19. f. 1.—Leaves in terminal tufts. Cluſters compound, very long, drooping.—Native of the woody parts of the Blue mountains in Jamaica, flowering in February. This has the habit of *H. capitata*, and is remarkable for its leaves forming a ſort of umbel. *Bark* unequally furrowed, grey, of a brittle corky ſubſtance. *Leaves* from eight to ten or more, in a terminal, umbel-like tuft, ovato-lanceolate, on longiſh ſtalks; the central ones being largeſt. Cluſters a foot and half long, cylindrical, compoſed of innumerable, ſcattered umbels, on ſhort ſtalks.

7. *H. heptaphylla*. (Vitis heptaphylla; Linn. Mant. 212. Willd. Sp. Pl. v. 1. 1182.)—Leaves of ſeven-ſtalked, elliptical leaflets. Cluſters compound, very long; partial flower-ſtalks whorled.—Native of the Eaſt Indies. We have never ſeen it but in the Linnæan herbarium. *Stem* climbing. *Leaves* alternate, compound, on long ſtalks; leaflets alſo ſtalked; radiant, from five to ſeven, broader and ſhorter than in the laſt. *Cluſter* long, pendulous, compoſed of numerous ſtalks, whoſe ſhort partial ſtalks are irregularly whorled; the terminal ones tufted, all downy. *Flowers* ſmall. We refer it to this genus on account of its ſtrict affinity to the three preceding ſpecies.

8. *H. terebinthinacea*. Willd. Sp. Pl. v. 1. 1179.—Leaves of ſeven-ſtalked, elliptical leaflets. Cluſters compound; partial flower-ſtalks umbellate.—Native of woods in Ceylon. This we have not ſeen. Willdenow deſcribes it as differing from the laſt in its infloreſcence, and ſmooth *calyces*.

Hedera, in *Gardening*, compriſes plants of the ſhrubby, climbing, ever-green, and deciduous kinds; of which the ſorts moſtly cultivated in this climate are the common ivy (H. helix), and the five-leaved ivy (H. quinquefolia.) The firſt of which is a ſhrub of the paraſitical kind, which raiſes itſelf to a conſiderable height by means of the ſupport of walls, buildings, trees, or other ſimilar ways, inſinuating its fibres into their joints, crevices, barks, and other parts, and thereby eſtabliſhing and ſecuring itſelf. But where none of theſe ſorts of ſupports are met with, its ſtems trail upon the ſurface of the ground, and ſtrike root through the whole of their length, cloſely covering it ſo as to be eradicated with difficulty, as wherever the ſmalleſt portion of the ſtem is left it ſoon ſpreads and multiplies itſelf. But while the ivy plant is fixed to any kind of ſupport, or trails upon the ſurface of the ground, the ſtalks are ſlender and flexible; though after it has reached the extent of its ſupport, they become ſhorter and more woody, forming themſelves into large buſhy heads, their leaves being larger and more oval in their ſhape, but not divided into lobes in the manner of the lower leaves. And while the ſtems continue to trail on the ground, the plants do not produce any flowers, in which ſtate the ivy is denominated *barren* or *creeping* ivy; however, when the branches get above their ſupport, they produce flowers at the end of every ſhoot, which are ſucceeded by berries, formed into round bunches, that turn black before they get ripe. In this ſtate it is called *climbing* or berried ivy. In the old trees the bark is covered with an aſh-coloured chopped bark, which, in the young branches, is of a green or purple tinge.

It has been remarked by the late Mr. Curtis, that but few people are appriſed of the beauty of the ivy plant, when it is permitted to run up a ſtake, and ultimately to form itſelf into a ſtandard, as the ſingular complication of its branches, and

and the vivid hue of its leaves give it one of the firſt places among plants of the ever-green kinds in ſhrubbery grounds.

There are varieties of ivy with ſilver-ſtriped leaves, and with yelloviſh leaves on the tops of the branches.

The latter ſpecies has long ſlender ſhrubby climbing ſtems that riſe upon ſupport to a great height, by means of fixing themſelves in the crevices of the walls as they advance in height.

This plant is admirably calculated to cover the naked walls of elevated buildings, which it effects in a very ſhort period, as it is capable of ſhooting nearly twenty feet in the courſe of a year, but in conſequence of the leaves falling off in the autumnal ſeaſon, and being late before they appear in the ſpring, it is not held in much eſtimation by the gardener. But as it is but little affected by ſmoke or confined air, it may be found very convenient for covering buildings in large towns and ſome other places.

Method of Culture.—Both theſe ſpecies and varieties of plants are capable of being readily increaſed by their trailing branches, which throw out numerous roots to their very extremities. Alſo by planting the cuttings of the young branches in the autumnal ſeaſon in a ſhady border, which, as ſoon as they have ſtricken root, in the following autumn ſhould be removed into the ſituations where they are to remain and grow.

And they may be raiſed by ſowing the ſeed in the early ſpring months in a moiſt ſhady ſituation, providing ſuch as has been perfectly ripened.

In regard to the buſineſs of training the plants, nothing more is required than to direct a few of the principal branches againſt the walls or other places at firſt, when they will ſpeedily attach themſelves to them, and advance in their climbing growth.

It is obvious that theſe plants are capable of being made uſe of in many different ſituations of gardens and pleaſure grounds in the way of ornamental effect.

HEDERA *terreſtris*. See GLECHOMA.

HEDERICK, BENJAMIN, in *Biography*, was born at Giethen, a town of Miſnia, and loſt his father at a very early age, but having at this period laid the foundation of claſſical learning, he was ſent to Leipſic, and then to Wittenberg to finiſh his ſtudies. He next engaged as private tutor in a family, in which he continued more than ſix years, and being allowed free acceſs to the univerſity library, he improved himſelf in different branches of learning till he became teacher in the ſchool of a monaſtery near Magdeburg. In 1705 he was appointed rector of the ſchool of Groſſenhagen, where he ſpent the remainder of his life, employed either in the education of youth or in the compoſition of uſeful books. He died in the year 1748. His principal works are "Reales Schul-Lexicon," a dictionary of every thing that relates to geography, chronology, hiſtory, antiquities, &c.: and "Lexicon manuale Græcum." This was firſt publiſhed at Leipſic in 1722, and has been re-printed in almoſt all the countries of Europe; in England it has gone through many editions, and has been augmented by the labours of Patrick, Young, and Morell. The laſt-mentioned editor has given extracts from the preface of Auguſtus Erneſtus, in which he ſays "Hedericum illum, virum bonum cetera et laborioſum, ſed Græce doctum, et ad tale lexicon rite conficiendum ſatis a lectione Græcorum ſcriptorum inſtructum non fuiſſe; that Hederick was a good man, and laborious, but by no means a profound ſcholar in the Greek language, nor properly qualified to compile a lexicon for the illuſtration of Greek authors." Gen. Biog.

HEDESUNDA, in *Geography*, a town of Sweden, in the province of Geſtricia; 18 miles S. of Geſſle. N. lat. 60° 25'. E. long. 16° 49'.

HEDGE, in *Agriculture*, a name applied to ſuch fences as are formed from ſome kind of underwood plants, either in their living or dead ſtate; hence they are diſtinguiſhed into *living* and *dead* hedges. The former are conſtantly compoſed of ſome deſcription of hedge plants in their living ſtate, ſuch as the white-thorn, holly, &c.; while the latter are always conſtituted wholly of dead ſubſtances, ſuch as various kinds of bruſh-wood, thorn, hazel, &c., which have been cut down at a proper ſeaſon with this intention.

Live hedges, properly formed of white-thorn, are conſidered by many as not only the moſt common, uſeful, and ornamental, but, in ſoils ſuited to their growth, the moſt proper and leaſt expenſive of any. The methods of planting and rearing hedges of this ſort are extremely various, proceeding from the difference of ſoil, ſituation, and expoſure. See FENCE.

In conſtructing dead hedges, the moſt ſuitable materials are thoſe of the thorn kinds; which ſhould be well wattled together, by having proper ſupplies of good ſtakes and edders. See FENCE.

HEDGE, in *Gardening*, a ſort of fence employed occaſionally both for uſe and ornament in gardens, as for incloſing and dividing the internal parts of the ground and ſeveral other purpoſes.

Fences of this ſort are of two kinds, *dead* and *living*; but it is only the latter kind that is made uſe of in gardens. They are the cheapeſt and moſt ornamental fences that can be employed where walls, &c. are not neceſſary, for planting wall-trees againſt, and other ſimilar purpoſes.

And there are a great variety of ſhrub and tree plants, both of the deciduous and ever-green kinds, that may be occaſionally employed for hedges in garden grounds; the principal of which are, in the firſt ſort, white-thorn, black-thorn, crab-tree, alder, elder, poplar, willow, hornbeam, beech, elm, lime, privet, berberry, ſweet-briar, roſe, ſyringa, and honey-ſuckle.

Alſo in the latter kind, holly, yew, furze, laurel, lauruſtinus, phillyrea, alaternus, box, ever-green oak, ſavin, roſemary, pyracantha, and ſea-purſlain ſhrub, &c.

For outſide Hedges.—It is obvious that for this purpoſe the white or haw-thorn plant forms the beſt material, which, by being properly trained, by trimming or clipping annually, is rendered a quite cloſe, hardy, and durable fence. Hedges of this ſort may be formed by planting young plants or ſets raiſed from ſeed in the nurſery, which, when a year or two old, or when as big as a gooſe-quill, up to the ſize of the little finger, are proper for this purpoſe. See CRATÆGUS.

And the black or ſloe-thorn is alſo proper for garden-hedges, and forms a very ſtrong durable fence; but by its producing ſuch abundance of ſuckers from the root, it is leſs eſteemed; but as it is well armed with thorns, and of quick growth, it may be uſeful where the white-thorn cannot be procured in ſufficient quantity.

With reſpect to hedges of this nature, they may be raiſed by ſowing or ſetting the ſeed or ſloes in autumn, when fully ripened, in one or two ſmall drills or trenches in the place where the hedge is to be, at the diſtance of five or ſix inches, or more, from each other, and to the depth of two or three inches. Where there are two rows, they may be about ſix or eight inches apart, ſo as to have room for cleaning them.

But it is a much better method to firſt raiſe the plants in the nurſery

nurſery till of a proper ſize, as two years old, and then plant them out in rows as above-directed.

Plants of the crab-tree, of the apple, as well as thorny ſorts, are ſometimes planted for hedges; but the plants for this purpoſe ſhould be ſuch as are raiſed from the kernels of the wild crabs, which come up more thorny than thoſe of the cultivated kinds, and ſhoot more branchy and cloſe, quite from the bottom. Theſe ſhould, however, only be made uſe of, as being of quick growth, and where the others cannot be procured in plenty.

The hedges of theſe kinds may either be raiſed by ſowing the kernels of the fruit in autumn or winter, in the place where the hedge is intended, in drills, the whole length an inch deep, covering them that depth with earth, or the plants raiſed firſt from ſeed in the nurſery, which, when a year or two old, may be planted out. Some of the plants of the hedge may, in this way, be ſuffered to grow up, and afford an annual crop of crabs for verjuice. A proper number of the plants may likewiſe be uſed, as they ſtand in the hedge, for ſtocks to graft on with uſeful family or cyder apples. Theſe methods however ſeldom anſwer any good purpoſe.

Elder plants are alſo uſed for outward hedges, where a fence is wanted as quickly as poſſible, as being very expeditious in their growth, though not the moſt beautiful. Hedges are likewiſe readily formed by planting large truncheons or cuttings of the ſtraighteſt upright ſhoots and branches, from two or three, to ſix feet long, planted either upright, a foot diſtance, and wattled along the top to preſerve them firm and even, or placed ſlanting acroſs one another checquer-wiſe, forming a ſort of lattice-work, which is the moſt effectual method. In either way of planting the lower ends of the cuttings, muſt be ſharpened, making holes to receive them, fifteen or eighteen inches deep, either in the level ground, or the ſides or tops of the banks, where they are to be planted.

And the alder is alſo proper to plant for hedges in wet or marſhy grounds, as being an aquatic, and growing readily by ſmall or large cuttings like the elder. It quickly forms a hedge.

This is very proper on the borders of rivers, brooks, or other waters, as its roots, and numerous ſuckers ariſing from their lower parts, form ſuch a cloſe thicket, as effectually to preſerve the earth of the banks from being undermined, and waſhed down by the water.

Alſo the Lombardy poplar, as emitting numerous ſide-branches quite from the bottom, and being of very quick growth, is alſo occaſionally employed to form an expeditious outward hedge along the ſide or top of a bank or ditch, or to train as a loftier hedge for ſhelter, ſhade, blind, and other purpoſes.

Indeed, hedges of this plant are formed at once, if wanted, of five or ſix feet or more in height, by having young trees, well-branched from the bottom, heading the top to the above height, and planting them in a ſingle row a foot or two aſunder. Younger ſets of two or three feet in height may be planted and trained. When deſigned as an outward hedge, they ſhould generally have an outſide ditch. They may be kept to an orderly thick growth, by proper clipping in the ſummer ſeaſon when it may be neceſſary.

Willow is alſo ſometimes planted to form outward hedges along the ſides of watery ditches, brooks, rivulets, &c. or any marſhy or moiſt ſituation. They are planted either by ſmall cuttings, or larger long ſets of ſeveral feet, and inſerted in the manner directed for the older cuttings, ſo as to form an immediate hedge. In either method they run up quickly, and may be kept cloſe and regular by proper cutting in the ſummer ſeaſon.

And the holly forms an excellent and beautiful hedge. It is the beſt evergreen hedge that can be planted for an outward fence, as it grows cloſe, and is well furniſhed with leaves, which being armed with thorns, no cattle browſe upon them; and being always in foliage, it affords good ſhelter in winter, and is ornamental at all ſeaſons. The only objection to it is, its ſlowneſs of growth the firſt four or five years. The holly makes a beautiful garden hedge in mixture with the hawthorn.

Hedges of this ſort of plants are formed either by ſowing the ſeeds at once in the places where the hedges are to be, in drills an inch and a half deep; or by planting young plants of two or three years old from the nurſery: this is rather the beſt practice. They may be planted in one or two rows; though two rows planted a foot aſunder, and the ſame diſtance in each row, form the thickeſt and moſt effectual hedge. They may be kept in order by clipping once or twice a year, or as there may be occaſion.

Yew is occcaſionally uſed as a boundary hedge, and when full grown, is very thick and cloſe, and has a good appearance.

It is neceſſary that theſe hedges ſhould be guarded by a ditch or bank on the outſide. They are beſt raiſed by ſetting the young plants after they have been raiſed from the berries.

The furze plant is ſometimes uſed for an outward evergreen hedge, but which makes only an indifferent one, being apt to die off in gaps. As it grows well, however, upon dry banks, or any poor dry ſoil, it may be uſed for a hedge in ſuch caſes: theſe are raiſed by ſowing the ſeeds in autumn at once in the place where it is deſigned to have the hedge, in drills an inch and a half deep, or more.

With regard to the general management of theſe hedges, it may be obſerved that all outward ones, deſigned as fences, ſhould have a ditch and bank; the ditch, &c. ſerving as a defence to the young hedge againſt cattle, &c. till it is grown up, and afterwards rendering the whole a more effectual outward fence. When planted on the level ground, they ſhould be defended with railings, open pales, hurdles, or a ſtake and buſh dead hedge, till advanced to the above growth. Where a ditch and bank is intended, the ditch on the outſide ſhould be three feet wide at top, two or three deep, ſloping to one ſide at bottom; raiſing a low bank on the inſide on which to ſet the plants, which may be planted either on the ſide of the inner bank in two rows one above the other a foot aſunder, as commonly practiſed for quick hedges, putting them in, in forming the ditch and bank; or be planted entirely on the top of the bank, firſt forming the ditch and bank, and levelling the top ſo as to form a ſort of border or bed extending longways, planting the ſets in one or two rows the whole length; but two rows a foot aſunder is the moſt eligible for all outward fences, as they always form the thickeſt, ſtrongeſt, and moſt effectual hedge-fences.

In which-ever way the planting is performed, the roots of the ſets ſhould always be bedded in on the fineſt looſe mellow mould that can be procured. With this care large plants will ſucceed in the moſt perfect manner, and ſoon form excellent hedges.

For Diviſion Hedges.—When hedges are deſigned for middle fences to divide grounds, two-ſided banks are uſually raiſed a yard high, and as broad at top, having a ſlight ditch on each ſide of the bank, and the different ſides of the bank formed with ſquare ſpit-turfs from the adjoining ground,

ground, and the middle filled up with mould from the ditches on each ſide; ſo that, when finiſhed, it forms a yard-wide bed all the way on the top. Along the middle of this plant two rows of hedge-ſets, or ſow the ſeed in drills as has been directed above.

But where no ditch or raiſed bank is required, the place for the hedge ſhould be marked out on the level ground, two or three feet broad, digging it along, one or two good ſpade's depth. The ſets ſhould then be planted in one or two rows, ranging along the middle; or the ſeeds ſown at once, where it is intended to have the hedge in two drills, a foot aſunder, the whole length. For interior garden hedges one row is generally ſufficient, either of ſets planted or ſeeds ſown. In this mode, where the ſets are of a tolerable large ſize and ſtrength, it will be proper to form a trench, in which to plant each row, with the roots all a regular depth, and the tops upright; or, if quite ſmall young ſets, they may be planted with a dibble, but the former is the better mode.

In the firſt method, one or two narrow branches ſhould be formed longways, for a ſingle or double row of ſets with the ſpade, by cutting out a narrow trench ſix or eight inches deep all along, for each row of plants, making one ſide upright; then the ſets ſhould be placed in the trench againſt the upright ſide, ſix, eight, or ten inches aſunder in the row, with their tops all upright, ſeveral inches above the ground; turning in the earth directly upon the roots, &c. to the depth of the trench, treading the earth thereto moderately firm, to fix the plants in the proper poſition as the work proceeds;—and if intended to plant two rows of ſets to form a double hedge, make another trench a foot diſtance; placing thoſe of the ſecond trench oppoſite to the interval ſpaces of the firſt row of ſets, earthing them in regularly as the others, and treading the whole down cloſe to the ſets, evenly along the ſurface in the line of the hedge.

And in trench-planting, the ſets may likewiſe be put in, by planting them as you proceed in digging the trench out, working out with the ſpade a foot-wide trench, digging out a ſpade depth of earth at one end, the width of the trench, then placing a ſet therein cloſe to one ſide; or, if intended to have a double hedge, placing two ſets, one to each ſide of the trench; and then, in either method, proceeding in digging, turning one or two ſpades of earth in upon the roots of the ſets; and at eight or ten inches from theſe, plant one or two ſets more in the ſame order, digging and earthing them in as the others; and thus proceed, digging along and planting the rows of ſets as the work advances; obſerving in double rows to place the ſets oppoſite to the intervals in the rows of each other.

In planting with the dibble, the ground ſhould be previouſly well dug over a ſpade's depth; then trimming the ſtraggling roots and tops of the plants with the dibble, make a hole for each ſet at the above diſtances, inſerting the roots a proper depth, and cloſe the earth well about each ſet as they are planted.

In forming hedges by ſowing the ſeeds at once in the intended places for the plants to remain, the ground ſhould be properly dug, and then either one drill for a ſingle row, or two for a double hedge, ſhould be formed a foot aſunder, ſowing the ſeed tolerably thick in them, and covering it an inch or two in depth with the earth. The place ſhould be kept very clear from weeds, both before and after the plants appear; and if the plants are any where too thick, they may be thinned out at the proper ſeaſon.

All ſuch hedges as are expoſed to cattle, muſt, as ſoon as planted, be protected either with a ſtake and buſh hedge, hurdles, or rails, for four or five years till they grow up. They ſhould alſo be duly hoed and weeded while young, and kept very well cleared from all ſorts of weeds. This ſhould be particularly attended to the firſt two years of their growth.

And where deſigned to be trained, they ſhould be annually clipped over in ſummer, being topped ſparingly while young, only juſt trimming off the tops of the ſtraggling and run-away ſhoots, to preſerve a little regularity, that the whole may advance equally, and promote lateral wood to thicken them as they advance, and cut in moderately on the ſides. But when arrived at nearly their proper height, as four, five, or ſix feet, or more, they may be trimmed in cloſe on the ſides and tops annually, to preſerve them thick and within their proper bounds, cutting the ſides always firſt as even as poſſible; then the tops, which ſhould alſo be cut as even as a line, always cutting in nearly to the old wood of the former year's clipping, otherwiſe the hedges will be too broad; the tops being always kept narrower than the bottoms, in order that they may not become thin.

The neateſt mode of cutting them at the tops is that of the ridge form, which is eaſily done by a proper tool.

It is well known that regular hedges were formerly in great requeſt in gardens: almoſt all the different compartments and diviſions of pleaſure-grounds were ſurrounded with them, being formed of various ſorts of trees and ſhrubs, both evergreens and deciduous, which being neatly trained and clipped once or twice annually, ſometimes appeared very ornamental; but from their ſurrounding, ſhutting out, and obſtructing the ſight of the different ſhrubbery borders, clumps, and other parts, as well as their concealing the grounds, and appearing ſtiff and formal, they are at preſent little in uſe. They are only introduced occaſionally, either as outward or diviſion fences, or for ſhelter, ſhade, &c. in particular compartments, and to cover unſightly objects, or parts of the gardens.

The hedges formed of lofty elm, lime, beech, and ſome other ſorts of deciduous trees in pleaſure-grounds, for ornamental training, are alſo laid aſide, as being ſtiff, aukward, and troubleſome in keeping in order. And the various fancy devices in hedge-work have likewiſe given way to a better and more eaſy rural taſte in garden grounds.

In addition to what has been ſaid on hedges, formed of the more common ſorts of plants, it may be obſerved, that the laurel, though a ſingularly beautiful evergreen adorned with a noble large foliage, forming various ſhoots, never grows ſo compact, or is ſo eaſily kept in form as ſome other ſorts; beſides its leaves being very large, when clipped with ſhears, they are unavoidably cut through, and ſo ſtubbed and mangled as to have a diſagreeable appearance. In theſe hedges, therefore, inſtead of performing their annual trainings with ſhears, the ſhoots ſhould be trimmed off with a knife, to preſerve the leaves entire. This plant is proper to train hedge-faſhion to hide any diſagreeable fence, and will grow either under trees, in the ſhade, or in an open expoſure, and is of quick growth. Hedges of this nature ſhould be planted in one row, at from 18 inches to three feet diſtance, according to the ſize of the plants at the time of planting them out in the line of the fence.

The lauruſtinus, from its being not only an evergreen, but a beautiful flowering ſhrub, forms a delightful hedge for ornament, as it is covered with flowers in winter and ſpring. It is alſo well adapted for training hedge-faſhion againſt any ſhabby fence or naked wall. In either method, it ſhould be planted in one row, at from 18 inches to three feet diſtance in the line.

The phillyrea and alaternus, being beautiful evergreens, form very ornamental hedges. They greatly reſemble each other;

other; but the phillyrea being the ſtrongeſt grower, as well as thickeſt ſhooter, is the more proper for a hedge; for variety both may be uſed: they are alſo good evergreen ſhrubs for training hedge-faſhion againſt unſightly or naked walls, or paling fences, as they ſoon cover them; and if the common green and variegated kinds are intermixed, in either mode of hedge-work, they have a delightful effect at all ſeaſons of the year. They ſhould be planted in one row, at from about 15 or 18 inches, to two or three feet diſtance between plant and plant in the lines of the fences.

The bay is alſo capable of forming a tolerable evergreen hedge for variety, and may be led up ſix or ſeven feet high, placing the plants half a yard diſtance from each other in the lines.

The evergreen oak is likewiſe a proper plant to form a tall hedge, as it may be trained 15 or 20 feet high, if required. It ſhould be planted in one row, ſetting the plants one, two, or three feet aſunder, according to their ſize or ſtrength.

The evergreen privet will alſo form a handſome good hedge, five or ſix feet high, by planting the ſets a foot aſunder, and training it up narrow at top in the manner noticed above.

The tree box makes a very cloſe and beautiful low evergreen hedge, four or five feet high, when the ſets are planted about a foot aſunder in the rows of the hedge.

The leſſer ſorts of evergreens are ſometimes employed for variety to form moderate hedges, from about three or four to five or ſix feet in height; they ſhould be planted in a row at from 12 to 18 inches, to two feet aſunder in the lines.

All ſorts of evergreens are proper for hedges, when from about 12 or 18 inches, to two or three feet in height, though the holly ſucceeds better when planted in its younger growth.

The proper ſeaſon for planting them is either in autumn or in the ſpring; for it is not ſafe to tranſplant evergreens in the middle of winter. Where the ſoil is moiſt, the latter is the beſt period; but in dry gravelly ſoils, the former anſwers perfectly.

In planting theſe ſorts of evergreens, for middle or internal hedges, no ditches or banks are neceſſary as for outward hedges or fences; ſo that in the place where the hedge is deſigned, a ſort of border ſhould be marked out the whole length, two or three feet wide, and dug or trenched over for the reception of the plants: the plants need only, in theſe caſes, be planted in a ſingle row or line.

Among the deciduous plants, the hornbeam forms a beautiful ſummer hedge, being a moderate but very cloſe ſhooter, well furniſhed with leaves, and capable of being trained up from ſix or eight, to about 12 or 15 feet high; but the leaves, though they wither in autumn, remaining firmly attached to the branches all winter, make but a ſhabby appearance at that ſeaſon. It is, however, on this account ſuperior to moſt other deciduous hedges for the purpoſe of forming ſhelter in the winter. For hedges it ſhould be planted in ſingle rows, at about half a yard aſunder in the plants, to form a cloſe moderate hedge as ſoon as poſſible; but if deſigned to be brought up pretty tall, and the plants are ſpreading, they ſhould be ſet about three feet diſtant in the rows or lines.

The beech alſo forms a cloſe regular hedge, from about ſix or eight to fifteen or twenty feet high: the leaves withering on the branches in autumn, continue dropping off moſt part of the winter. Theſe plants ſhould be planted in the ſame manner as the hornbeam.

The elm forms a cloſe, even, and beautiful hedge, and may be trained from ſix or eight, to ten, twenty, or thirty feet high, forming a cloſe fence from top to bottom. The plants for this purpoſe may be from three or four, to eight or ten feet or more in height, and ſhould be planted in a ſingle row from two or three, to ſix or eight feet diſtant, according as they are leſs or more ſpreading, and as wanted to form a cloſe hedge as ſoon as poſſible.

The lime-tree is ſometimes employed for ornamental hedges for variety, but is much inferior to the other deciduous ſorts, as it becomes thin and ſhabby by clipping, and is thinly leaved.

Other low kinds of ſhrubs of this ſort are ſometimes employed for variety: ſome ſorts, ſuch as roſes, honey ſuckles, and ſyringas, when formed into low hedges, beſides their property as hedges, produce great quantities of flowers, and afford a fine fragrance.

The plants for this uſe are of a proper ſize when from about one foot to a yard in height, according to the ſorts. It is beſt to plant them young, chooſing ſuch as are well furniſhed with plenty of ſide or lateral ſhoots, that they may form a cloſe head quite from the bottom. They may all be planted either in autumn or early ſpring, in open weather. The method of planting them is nearly the ſame as in the evergreen kinds.

Theſe ſorts of hedges ſhould be trained and clipped in the ſame manner as directed above.

In order to keep garden hedges in perfect good order, they ſhould be clipped twice every ſummer: the firſt time about Midſummer, when they have made their ſummer ſhoot; and the ſecond clipping towards the middle or latter end of Auguſt. But where this is done only once in the ſummer, the clipping ſhould not be performed until the beginning of Auguſt, as when cut ſooner the plants ſhoot again, and appear almoſt as rough the remainder of the ſummer, and all winter, as if it had not been done at all, which renders ſuch hedges very unpleaſant to the eye. See FENCE.

HEDGES, *Eſpalier*. See ESPALIER.

To line a HEDGE, in *Military Affairs*, is to plant muſketeers along it under cover; either to fire upon an enemy that is advancing to ſave themſelves from the horſe, or to defend a paſs or defile.

HEDGE-*hog*, in *Zoology*. See ERINACEUS.

Sea-HEDGE-*hog*. See CENTRONIA and ECHINODERMA.

HEDGE-*hog*, in *Botany*. See MEDICAGO.

HEDGE-*hog-thiſtle*. See CACTUS.

Spaniſh HEDGE-*hog-thorn*. See ANTHYLLIS.

HEDGE-*hog*, or *Weir-hedge*, in *Engineery*, is a temporary erection of wood, to collect the ſilt and contract the wide parts of rivers. See Smeaton's Report, v. i. p. 118.

Sir Thomas Hyde Page, Mr. Samuel Crawley, Mr. Anthony Tatlow, and others, have practiſed this method of gaining land from wide rivers; on the Trent this was accompliſhed on a conſiderable ſcale by merely ſtaking down rows of furze faggots, as mentioned in our article CANAL.

HEDGE-*hyſſop*, in *Botany*. See GRATIOLA.

HEDGE-*muſtard*. See ERYSIMUM.

HEDGE-*nettle*. See GALEOPSIS.

HEDGE-*nettle-ſhrub*. See PRASIUM.

HEDGE-*ſparrow*, in *Ornithology*. See MOTACILLA *Modularis*.

HEDGE-*clipping Machine*, in *Gardening*, a ſort of machine ſcaffolding, or ſtage, formed ten, twenty, or thirty feet high, or more, with platforms at different heights, to ſtand upon, the whole being made to move along upon four low wheels. It is compoſed of four long poles for uprights, well framed together, eight or ten feet wide at bottom, narrowing

narrowing gradually to four or five at top, having a platform or ſtage fixed at every ſeven or eight feet of height, with one near the top, each having a rail waiſt-high: there is a ſort of ladder formed on one ſide to aſcend by, &c. Upon this machine a man or two may be employed on each ſtage or platform, trimming the hedge with ſhears, and ſometimes with a light garden hedge bill, fixed in a handle from three to five or ſix feet long, which is more expeditious, though it will not make ſo neat work as cutting with ſhears. It is very uſeful in clipping high hedges or trees. And it may be employed for dreſſing, cleaning, pruning, and nailing different ſorts of trees, as well as various other purpoſes. In extenſive pleaſure-grounds and gardens theſe machines are eſſentially neceſſary in various intentions.

HEDGE-*fence*, a term applied to that ſort which conſiſts of ſome kind of hedge. See FENCE.

HEDGE-*row*, a term denoting the line or direction of a hedge-fence; which in general ſhould be ſet out as ſtraight as poſſible. It is of great advantage to have the hedge rows well cleared up and freed from all ſorts of trumpery both of the weed and buſhy kind, as by ſuch attention much land is not only gained, but great convenience experienced, as well in feeding as ploughing ſuch grounds.

HEDGE-*row-timber*, a name applied to that kind which is raiſed in the hedge rows of fields. The growing of timber in hedge-rows, is not, however, by any means, a method of practice that ought to be generally adviſed, though, in particular inſtances, it may perhaps be had recourſe to with propriety and advantage. The great inconveniences in ſuch caſes are, that the trees ſoon produce gaps in the hedges by their ſhade and droppings, and at the ſame time do great injury to the crops; while their roots obſtruct the operations of the plough. Great numbers of trees in the ſtate of pollards, are frequently met with in particular diſtricts, which, while they diſguſt by their appearance, are alſo highly injurious to the hedges, and ſhould never be ſuffered to continue in ſuch ſituations longer than can poſſibly be avoided. See POLLARD and TIMBER.

HEDGING, the practice of forming and repairing fences of the hedge kind. This is a ſort of work that is but ſeldom well executed, though it is of the utmoſt importance to the proprietor of lands to have it performed in the moſt perfect manner, in the view that he may be as ſecure as poſſible from the danger of ſtock breaking in, and at the ſame time have his hedges in neat order.

The proper ſeaſon for the performance of work of this nature, is any time during the winter months, when the ſtate of the weather will admit of it; as from about the beginning of November to the latter end of March, but not by any means earlier or later, as in the former caſe the buſineſs could not be properly done; while in the latter there would be danger to the plants from the riſing of the ſap in them.

It is always a good practice to have the hedges of farms made and repaired in a complete manner, as ſoon as poſſible after the tenants enter upon them; they being afterwards apportioned in ſuch a way as that a certain extent may be done annually. By this means they may be kept in a proper condition with much greater eaſe and facility.

In regard to the moſt proper modes of executing this ſort of buſineſs, they can only be directed by the nature and ſtate of the hedges. It ſhould, however, be a rule to avoid as much as poſſible all ſorts of dead hedges, as they are not only conſtantly attended with great expence but of ſhort duration. As there ſhould always be as little mixture as poſſible of living and dead materials in hedge fences, plaſhing is a practice that anſwers well in old thin hedges, as it keeps them up, and they conſequently laſt much longer than where much dead matters are made uſe of in them; and form a far better defence againſt live ſtock.

Immediately after the hedges have been properly made and repaired, the ditches on their ſides, where they may have any, ſhould be well ſcoured and cleaned out in order that the water may readily get off from them. All the bruſh and other wood ſhould likewiſe be faggotted, and brought away, in the view of being placed in proper ſtacks near the farmſtead, and thus the field be left free from all ſorts of rubbiſh of that nature. See FENCE.

HEDJADIE, in *Geography*, a town of Aſiatic Turkey, in the government of Diarbekir, on the Tigris; 35 miles S.S.E. of Tecrit. N. lat. 60° 25'. E. long. 16° 49'.

HEDJAS, a province of Arabia, lying along the Arabic gulf, between Mount Sinai and Yemen, and extending inland as far back as to the confines of Nedsjed; it is bounded on the E. by Nedsjed, on the N. by the deſart of Sinai, on the S. by Yemen, and on the W. by the Arabic gulf. From the ſea-ſhore, a plain, varying in breadth, ſtretches backwards to the bottom of a chain of mountains, running in a direction parallel to the Red ſea. This plain is ſandy and barren, with the exception of the openings of the vallies, watered by torrents from the mountains. This barren plain cannot be populous. Jambo, Jidda, and Ghunfude are the only towns or harbours on the whole of this extenſive coaſt. The other villages interſperſed here and there are too few and too inconſiderable to deſerve notice. In the interior parts there is no city of any importance except *Taaif*; which ſee. The two capitals of Hedjas are *Mecca* and *Medina*; which ſee reſpectively. The highlands of Hedjas produce abundance of fruits, and other commodities of various kinds. Balm of Mecca is obtained from theſe lofty regions, and chiefly from the extenſive mountain of Safra, at the diſtance of three days journey from the Arabic gulf. Theſe highlands are poſſeſſed by a number of independent ſovereign ſcheicks; of whom the moſt powerful is the ſcheick of the tribe of Harb, who can bring into the field 2000 men. His domains contain ſeveral cities and a number of villages. During the months favourable for paſturage the moſt diſtinguiſhed perſons of this tribe live in tents; and in the other parts of the year, they inhabit towns and villages. Thoſe of the lower claſs live, commonly through the whole year, in huts thatched with graſs. This principality is ſituated upon the mountains between Mecca and Medina. The other independent ſcheicks in this province live with their ſubjects in towns and villages, through the whole year, and for their defence occupy ſome caſtles built upon precipitous rocks. They ſometimes join their neighbours to attack the Turkiſh caravans; but theſe never paſs through *their* dominions. The chief of the tribe of Harb is the perſon who principally haraſſes the caravans, and lays them under contribution. The moſt remarkable and leaſt known of theſe highland communities, is that which the Jews have formed upon the mountains lying N E. of Medina, in a tract of country called "Kheibar;" they have independent ſcheicks of their own, and are divided into three tribes. They are very odious to the Mahometans, who unjuſtly accuſe them of pillaging the caravans, ſo that in Syria the greateſt affront that can be offered to a perſon is to call him "Beni Kheibar." Theſe Jews do not ſeem to keep up any intercourſe with their brethren who are diſperſed over Aſia. They belong to the ſect of the Karaites, who are not numerous, and are much ſcattered; and by the other Jews, who are in general attached to the ſect of the Phariſees, are ſtill more deteſted than the Chriſtians or Mahometans.

The grand ſignior ſtyles himſelf ſovereign of Hedjas, and

ſome of our geographers take occaſion from hence to repreſent this part of Arabia as a province of the Turkiſh empire. But the authority of the ſultan is a mere ſhadow, and his power in Arabia conſiſts ſolely in a few trivial prerogatives. He ſends annually caravans to Mecca, with troops to protect them, that are often obliged to advance by force of arms. When he chooſes to oppreſs a weak neighbour, he can depoſe the reigning ſherriffe, and exalt another, while his caravan lords it at Mecca. He ſends a pacha to Jidda, who ſhares the government of the city with the ſherriffe, but who dares neither to go to the ſeat of his government, nor to return from it, unleſs when he can be protected by the great caravan. Laſtly, the Arabs ſuffer the Turkiſh ſovereign to maintain, for the ſecurity of the pilgrims, and in order to guard the walls, a few Janiſaries, cooped up in ſome wretched towns. The revenues which the ſultan draws from this province, and ariſing chiefly from duties paid at the cuſtom-houſe of Jidda, are not ſufficient to defray the expences of the pacha's houſhold. But in return for theſe ſcanty revenues, he is obliged to ſecure the favour of the Arabs by annual preſents, to allow penſions to the ſherriffes, and to the principal nobility of Hedjas, or guardians of the ſacred family. With theſe penſions, and the freight of four or five large veſſels, ſent every year to Jidda, laden with proviſions, he ſupports almoſt all the inhabitants of Mecca and Medina. While the pilgrims remain in the city of Mecca, as much water as 2000 camels can bear is daily diſtributed gratis, not to mention the great number of preſents with which he adorns the "Caaba," and gratifies the deſcendants of Mahomet. The ſultan no longer commands reſpect upon the Arabic gulf. Poſſeſſing only a precarious authority over Egypt, and having but a poor navy, he cannot hinder the Arabs from plundering Turkiſh ſhips, whenever they approach near enough to the ſhore, nor yet puniſh ſuch acts of inſolent piracy. Niebuhr's Travels.

HEDLINGER, John Charles, in *Biography*, an artiſt and die-cutter, was born at Schweitz in the year 1691. He was intended by his father for buſineſs, but his own inclination led him to ſtudy the fine arts, and while he was very young, he determined upon becoming a die-cutter, for which he had prepared himſelf by learning to draw. He reſolved to be his own inſtructor, not being able to bear the tedium of regular leſſons from a maſter in the profeſſion. He accordingly began to cut dies without any aſſiſtance, forming the tools which he employed, and he ſoon gave promiſe of excelling in the art. He was at length placed under the care of William Cramer, director of the mint, by whoſe aſſiſtance he made a rapid progreſs. In 1712 he ſerved as a lieutenant among the volunteers at the battle of Toggenbrug; and in 1717 he viſited Paris, where he applied himſelf to his buſineſs with great ardour, and where he was ſoon engaged to execute ſome medals for his majeſty, by whom he was preſented with a gold box. He next went to Sweden, and was made director of the mint, a place that was conferred upon him for life, and, independently of the ſalary, he was paid for all the pupils he inſtructed in his art. In 1723 he was invited to Ruſſia, with the offer of being appointed medalliſt to Peter the Great, an honour which he declined, being well ſatisfied with the protection and patronage of the queen of Sweden. He conceived an earneſt deſire of viſiting Italy, and having obtained permiſſion for this purpoſe, he left Stockholm in 1726, and continued his tour as far as Naples, where he not only examined every thing worthy of notice, but extended his acquaintance with eminent artiſts. At Rome he executed a medal of pope Benedict XIII., and made an excellent likeneſs, though he had only ſeen him occaſionally. In about eighteen months he returned to Stockholm, and ſtruck ſeveral medals relating to Swediſh commerce, manufactures, and mines, with a chronological ſeries of the Swediſh kings. He was now invited by many of the crowned heads in Europe, and ſtruck medals of the empreſs of Ruſſia; the princeſs Anne of Mecklenburg; and other diſtinguiſhed perſonages. In 1741 he returned to his native land, where he married. After paſſing ſome years, partly in Switzerland, and partly at Stockholm and Berlin, at length he ſettled in his own country, and died at Schweitz of a fit of apoplexy in March 1771, at the age of eighty. All his medals were engraved and publiſhed in Switzerland, under the title of "Œuvres de Chevalier Hedlinger," to which is prefixed an account of his life. Gen. Biog.

HEDON, or Heydon, in *Geography*, a borough, market town, and pariſh, in the diſtrict of Holderneſs, and Eaſt-Riding of Yorkſhire, England, is ſeated on a ſmall creek of the Humber, at the diſtance of ſeven miles from Hull, and 178 north of London. In the year 1800 its population was aſcertained to conſiſt of 592 perſons, and its houſes 144. Here were formerly three churches, but only one remains. It ſent members to parliament in the 23d year of Edward I.; but diſcontinued to return again till the firſt of Edward VI. The corporation conſiſts of a mayor, recorder, two bailiffs, and nine aldermen; and the number of freemen, having the right of voting, is about 140. The right of election is obtained either by deſcent, by apprenticeſhip, or by honorary gift. Here are a weekly market on Saturdays, and four annual fairs.

HEDONA, in *Botany*, from *ἡδονη*, *pleaſantneſs*, on account of the elegance of its flowers.—Loureir. Cochinch. 286.—This genus, which was founded by Loureiro, and which he conſiders as cloſely allied to *Dianthus*, having miſtaken the bracteas for ſcales of the calyx, appears to be the *Lychnis coronata*, Willd. Sp. Pl. v. 2. 808; *L. grandiflora* of Jacquin, fig. 3 in his Icon. Rar. t. 84.

HEDWIG, John, in *Biography*, a botaniſt particularly celebrated for his diſcoveries relative to the fructification of Moſſes, and for a new and very ingenious generic diſtribution of them, which was the reſult of thoſe diſcoveries, (ſee Fringe *of Moſſes*,) was born Oct. 8. 1730, at Cronſtadt, in Tranſylvania, where his father filled a reſpectable ſtation in the magiſtracy. After the firſt rudiments of domeſtic education, and with them an ardent fondneſs for the cultivation and obſervation of plants of all kinds, had been imbibed under his parents' roof, he ſtudied for four years at the public ſchool of his native town. On the death of his father in 1747, though he inherited but a very ſlender patrimony, he was enabled to go for further improvement to the univerſity of Preſburg in Hungary, where he remained two years, and then proceeded to Zittau in Upper Luſatia, led by the fame of the rector Gerlach, a learned grammarian, a relation probably of Stephen Gerlach; ſee that article. In 1752 he removed to Leipſic, where his diligence and talents, as well as his perſonal character, procured him the favour and friendſhip of the celebrated Ludwig in particular, by whoſe lectures of various kinds, as well as thoſe of Hebenſtreit, Boehmer, and others, he rapidly and abundantly profited. Hedwig uſed often, in after life, to expreſs his regret, that Ludwig had been too much occupied by the practice of phyſic and other buſineſs, to perfect a ſyſtem of botanical arrangement which he had in contemplation, as well as to bring the phyſiology of plants to greater perfection. So much eaſier is it to ſpeculate than to execute! ſo greatly do the miſts which envelope unexecuted ſyſtems magnify their ingenuity! Ludwig had already publiſhed on botanical phyſiology as well as arrangement. His works are marked with genius, but not of the firſt order. They

are rather the performances of a profeſſor, who felt himſelf obliged to do ſomething, but would have found it difficult to go much further, nor did even Hedwig under him imbibe any thing of the true philoſophical principles of arrangement, the talents for which are granted to very few, and are ſcarcely ever of German growth. We mean no invidious reflections on any nation or people. Each has its appropriate merits, and all are uſeful together in ſcience, like different characters on the theatre of human life.

In 1756 young Hedwig was taken into the houſe of profeſſor Boſe, to aſſiſt him in the demonſtration of plants in his botanical lectures, as well as in the care of patients at the Infirmary; and it is ſuppoſed that this engagement was full as advantageous to the maſter as to the pupil. Like Haſſelquiſt, he was obliged to turn his abilities to various methods for the augmentation of his ſcanty income, and his ſobriety and economy enabled him to live decently on what he could procure, and to purſue every means of improvement within his reach. Having finiſhed his ſtudies, he was deſirous of ſettling as a phyſician in his native place, but was prevented by an excluſive law in favour of ſuch as are educated in ſome Auſtrian ſchool. In 1759 he took his degree of Doctor of Phyſic at Leipſic, on which occaſion he publiſhed a theſis on the uſe of emetics in acute fevers, and was induced, by the perſuaſion of a mercantile friend at Chemnitz in Saxony, to eſtabliſh himſelf there, having married a young woman of good family at Leipſic. He was now ſo far maſter of his own time, that he found himſelf able to alleviate the labours of his profeſſion by almoſt daily attention to his favourite ſtudies. No longer under the guidance of profeſſors, he was now left to improve himſelf, in the very beſt of all ſchools, that of Nature. His morning hours in ſummer, from five till breakfaſt-time, were ſpent in the fields and woods, and his evenings in the inveſtigation of what he had collected, or elſe in the care of a little garden of his own. The acquiſition of an excellent compound microſcope, from his friend Koehler of Dreſden, proved of the utmoſt importance in deciding and aſſiſting the peculiar bent which his mind was now taking, for the ſtudy of the minuteſt kinds of plants, as well as for ſcrutinizing the anatomy of all. To purſue with ſucceſs his enquiries relative to theſe matters, he found it neceſſary, at 40 years of age, to learn drawing, as well to aſſiſt his own memory, as to communicate his diſcoveries to others. Hence he has been enabled to publiſh ſome of the moſt curious and authentic botanical figures.

The firſt and greateſt fruit of Hedwig's labours, was the determination of the male and female flowers of moſſes, the parts of which had been made out by Micheli, at leaſt in a great meaſure, and even the true office of each ſuggeſted; but the theory of the whole was firſt clearly detailed, as it was ſubſequently illuſtrated on every poſſible occaſion, by Hedwig. Juſt ſo Linnæus reviſed the obſervations of preceding philoſophers on the ſexes of plants in general, confirmed them by new ones, founded, in conſequence, a ſyſtem of arrangement, and to his lateſt hour elucidated both the one and the other by practical application. Yet the ſexual doctrine in both inſtances has been attacked, and Hedwig has ſtill a liberal adverſary in M. Paliſot de Beauvois, of whoſe opinions we propoſe to ſpeak in their proper place, under the article Moss.

Our author is recorded to have firſt beheld the bladder-like anther, of the Linnæan *Bryum pulvinatum*, diſcharging its pollen, on the 17th of January 1770. He was already ſatisfied that what Linnæus, miſled by Dillenius againſt his own previous opinion, had taken for anthers, were in fact the capſules of moſſes, and produced real ſeed. A hiſtory of his diſcoveries was publiſhed in a German periodical work, at Leipſic in 1779. In 1782 appeared his valuable *Fundamentum Hiſtoriæ Naturalis Muſcorum Frondoſorum*, a handſome Latin quarto, in two parts, with 20 coloured microſcopical plates. The earlieſt account given of Hedwig's opinions in England, was from the communications of the late profeſſor J. Sibthorp, who had juſt then viſited him, to the writer of the preſent article, in 1786, and it is annexed to a tranſlation of Linnæus's *Diſſertation on the Sexes of Plants*, publiſhed that year.

Hedwig loſt his firſt wife in 1776. She had brought him nine children, ſix of whom ſurvived their mother. This loſs, though deeply felt, was ſpeedily, and, as it ſeems, effectually ſupplied, by his marrying a very accompliſhed lady the following year, who was likewiſe a native of Leipſic. She perceived that the merits of her huſband were in a manner buried at Chemnitz, where his time was laboriouſly occupied for a ſlender remuneration, ſcarcely ſufficient to maintain and educate his family. Theſe conſiderations induced her to urge his removal to Leipſic, which took place at Eaſter 1781, and the following year the work above-mentioned was there publiſhed, on which his fame as an original phyſiologiſt and botaniſt moſt ſecurely reſts. The ſame ſubject is happily followed up in his *Theoria generationis et fructificationis plantarum cryptogamicarum Linnæi*, publiſhed at Peterſburg in 1784. This work gained its author the prize from that academy in 1783, of 100 gold ducats, which Linnæus had in 1759 obtained for his Diſſertation on the Sexes of Plants above-mentioned. In it the fructification and germination of Moſſes is further illuſtrated, and a view is alſo taken of the fructification of the other cryptogamic families, the author being very naturally deſirous of extending his diſcoveries throughout that obſcure tribe of plants. His ſucceſs has not been equal in all. In the *Hepaticæ* he has indeed fully eſtabliſhed his own doctrine, confirming what had been obſerved or believed by preceding writers, which may alſo perhaps be ſaid of his account of the *Fungi*, the obſcure, though not properly cryptogamic genus, *Chara*, and *Lichen*. His entirely novel explanation of the impregnation of *Equiſetum*, ſee that article, though wonderful, has not been controverted; but of the flowers of the proper ferns, neither he, nor any one elſe, has, in our opinion at leaſt, detected the ſecret; ſee Filices. A new and encreaſed edition of this work appeared in 1798.

The literary fame of Hedwig, and his medical practice, were now every day encreaſing. He was made phyſician to the town guards, profeſſor of phyſic and of botany at Leipſic. The latter appointment, in which he ſucceeded Dr. Pohl removed to Dreſden in 1789, was accompanied with a houſe, and the ſuperintendance of the public garden. In 1791 the ſenate appointed him phyſician to the ſchool of St. Thomas. The duties of all theſe various ſtations might be ſuppoſed to have fully occupied his time, yet he ſtill found leiſure to attend to new communications from his friends. Many nondeſcript moſſes were ſent him from Pennſylvania by the Rev. Dr. Muhlenberg, and many Weſt Indian ones by Dr. Swartz. A fine collection of new or rare ferns, in full fructification, was forwarded to him by ſir Joſeph Banks, at the ſuggeſtion of the writer of this, in hopes that he might be induced to take up their examination; it not being then known, in this country, that he was already intent on the ſubject, and preparing his eſſay for the Peterſburgh academy. The fruits of theſe communications were not given to the world in his life-time. But the former ones contributed, with other matter, to a poſthumous work, publiſhed by his able pupil Dr. Schwaegrichen, entitled *Species Muſcorum*, in 4to. with 77 coloured plates; and the

latter to ſome ſubſequent works of his ſon. If the plates of the *Species Muſcorum* be leſs elaborate or full than thoſe of his great work hereafter mentioned, the book is extremely valuable as a ſynopſis of ſpecies, and a ſummary of his knowledge on that ſubject.

The great and truly excellent work to which we allude, is his *Cryptogamia*, as it is generally called, entitled *Deſcriptio et Adumbratio microſcopico-analytica Muſcorum Frondoſorum, nec non aliorum vegetantium e claſſe Cryptogamicâ Linnæi novorum dubiiſque nexatorum*, in four volumes folio, with 40 excellent coloured plates to each. Of this the firſt volume came out in 1787; the laſt in 1797. In the figures the moſt minute parts are detailed with a fidelity rarely to be elſewhere ſeen, except in the cryptogamic publications of Hoffmann, Schrader, and Perſoon, for theſe are unrivalled. The letter-preſs is equally complete. Scarcely any thing can ever be added to the illuſtration of the ſubjects treated in theſe volumes of Hedwig, at leaſt of the moſſes, which compoſe the whole of them, except 14 plates in the ſecond.

The author lived to witneſs the general applauſe which his labours received, notwithſtanding ſome attacks made on his theories of impregnation by Gærtner, Necker, and others, and he enjoyed alſo the general reſpect of thoſe who knew or correſponded with him. But he was not exempt from domeſtic afflictions. Of ſeven children brought him by his ſecond wife, ſix had died in their infancy, and the only remaining one, a darling daughter, was taken from him at the age of 16, by a conſumption, in December 1797. His grief, locked up in his own breaſt, could not be diſſipated even by the ſcientific purſuits, to which he wiſely reſorted for the occupation of his thoughts. His health declined. A ſucceſſion of feveriſh attacks impaired his conſtitution, and he died of a typhus, after nine days confinement, on the 17th of Feb. 1799, aged 68. He left four children, all the offspring of his firſt marriage, two daughters and two ſons. Of the former, one married profeſſor Beck of Leipſic, the other Dr. Sulzberger of Burgſtaedt in Saxony. One of his ſons is an eminent painter at Magdeburg; the other, named Romanus Adolphus, adopted his father's taſtes and purſuits, ſettled as a phyſician at Leipſic, publiſhed two faſciculi of a ſplendid work on ferns, with coloured plates, as well as ſome phyſiological treatiſes, but unfortunately did not long ſurvive his diſtinguiſhed parent.

To ſum up the ſcientific character of Hedwig; as an obſerver and faithful deſcriber he cannot be ranked too high; as a vegetable phyſiologiſt, if not always infallible, he ſtands in the firſt order, and his knowledge was enhanced by modeſty, candour, affability, the ſtricteſt probity, and the moſt elevated piety. His ſyſtematic talents were inferior to his phyſiological ones. His methodical diſtribution of moſſes, and the genera he has eſtabliſhed, are altogether artificial in principle, though they prove in many caſes natural, without his having adverted to it. His ſpecific characters are ſeldom well conſtructed or defined, and his phraſeology liable to much exception. He adopts the expreſſion *ductorum faſciculus*, inſtead of the Linnæan *nervus* or *coſta*, for the ribs of the leaves of moſſes, though it is a diſtinction without a difference, and far leſs conciſe and commodious. We have already mentioned his overſight in calling the ſeeds of moſſes *ſporæ*, ſee GEMMA; though the adoption of that word tended only to overſet his own theory of impregnation, the whole end and aim of which were to prove them real *ſemina*. Hence he uſes *ſporangium* for *pericarpium*, or rather for that kind of ſeed-veſſel called a capſule, ſo that his term is both indefinite and ſuperfluous.

The ſame objections lie in full force againſt his *truncus*, which is a real *caulis*. We poſtpone all further remarks till we come to treat of the natural order of moſſes in its proper place. The memory of this illuſtrious botaniſt is preſerved by his friend Swartz in a fine Weſt Indian tree; ſee HEDWIGIA. For much of the above account we are indebted to a hiſtory of his life, annexed to his *Species Muſcorum*, by Schwaegrichen. He appears by a miniature portrait, in a ring ſent by his now deceaſed ſon to the writer of the preſent article, to have had a countenance marked with benevolence and intelligence. The latter perhaps is ſtill more ſtrongly indicated in a German print publiſhed ſeparately, while the medallion in the antique ſtyle, prefixed to his great folio work, has more of a mild and placid expreſſion. His complexion and hair were light, and his eyes of a blueiſh hazel. S.

HEDWIGIA, in *Botany*, ſo named by Swartz in honour of the great muſcologiſt; ſee HEDWIG. This juſt tribute had been paid him already by Ehrhart in the Hanover Magazine for 1781, and accepted by himſelf in his *Fundamentum Hiſtoriæ Naturalis Muſcorum*, part ii. p. 86; but the genus to which it was applied was afterwards ſunk in *Gymnoſtomum* by Swartz and others. Now it is, we believe with great propriety, reſtored, by the appellation of *Anictangium*, it muſt ever be regretted that the original name had been taken away, a moſs being much more appropriate to Hedwig than any other plant could be. See GYMNOSTOMUM.—Swartz. Prodr. 62. Ind. Occ. 670. t. 13. Schreb. 800. Willd. Sp. Pl. v. 2. 332. Mart. Mill. Dict. v. 2.—Claſs and order, *Octandria Monogynia*. Nat. Ord. *Tribilatæ*, Linn. *Meliæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cup-ſhaped, with four minute, ovate, acute, upright teeth. *Cor.* of one petal, tubular; tube the length of the calyx, contracted upwards; limb in four ovate, acute, erect, converging ſegments. *Stam.* Filaments eight, broad, inſerted into the baſe of the corolla, lying upon the germen; anthers minute, oblong, acute, converging over the ſtigma. *Piſt.* Germen ſuperior, conical, with eight furrows; ſtyle none; ſtigma obtuſe. *Peric.* Capſule large, three-lobed, (as if compoſed of three ovate pointed ones,) of three cells. *Seeds*, Nuts ſolitary, ovate, pointed, convex and very ſmooth on one ſide, rugged and uneven on the other; kernel of the ſame ſhape.

Eſſ. Ch. Calyx inferior, four-toothed. Corolla tubular, four-cleft. Style none. Capſule three-lobed, three-celled. Nuts ſolitary.

Obſ. This genus ſhould be placed between *Guarea* and *Amyris* in the Linnæan ſyſtem.

1. H. *balſamifera*. Swartz. Ind. Occ. 672. (Bois cochon; Nicolſon. Hiſt. de St. Domingue, 169, according to Swartz.)—Native of woods on the hills in the weſtern part of Hiſpaniola. A tall *tree*, rendered conſpicuous at a great diſtance in the woods by the whitiſh grey bark of its trunk. The branches are rather aſcending, but their extremities are often drooping or pendulous. *Leaves* alternate, ſcattered, erect, pinnate, a foot long, ſmooth; their leaflets on ſhort partial ſtalks, oppoſite, ovato-lanceolate, pointed, entire, ribbed, veiny, ſomewhat rigid. *Cluſters* about the ends of the branches, terminal and axillary, ſhorter than the leaves, erect, ſtraight, compound, with angular ſtalks. *Flowers* ſmall, whitiſh. *Capſule* as big as a large hazel-nut, with a coriaceous ſkin, full of an aromatic gum. *Nuts* hard, with an oily bitter kernel to each.—This tree flowers in May, and is called by the inhabitants of its native country *Bois de cochon*, or Wild-boar's tree, becauſe thoſe animals are, when wounded, reported to ſtrip off its bark, and heal their wounds with the gum that exudes from it.

it. This exudation is, according to Swartz, of a balſamic nature, very like balſam of Copaiva, both in ſcent and virtues. It is given in complaints of the cheſt or lungs, and is copiouſly procured by wounding the trunk of the tree.

HEDYCARYA, from ἡδὺς, *ſweet*, and καρυα, *a nut*, becauſe the tree in queſtion bears extremely ſweet nuts.—Forſt. Gen. 64. Linn. Suppl. 67. Schreb. 702. Mart. Mill. Dict. v. 2. Juſſ. 401. Lamarck Dict. v. 3. 78. Illuſtr. t. 827.—Claſs and order, *Diœcia Icoſandria*. Nat. Ord. *Scabridæ*, Linn. *Urticæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, flat-wheel-ſhaped, eight or ten-cleft; ſegments lanceolate, nearly equal. *Cor.* none.—Male, *Stam.* Filaments none; anthers numerous, about fifty, oblong, four-furrowed, barbed at the top, arranged along the whole baſe of the calyx.—Female, *Piſt.* Germens numerous, flat-globe-ſhaped, each ſtanding on a cylindrical pedeſtal, in the middle of the calyx; ſtyles none; ſtigmas little protuberances ſcattered over the germens. *Peric.* none. *Seeds*, ſix to ten ſtalked, globular, bony, ſingle-ſeeded nuts; kernels ſolitary, globular. *Recept.* woolly, in the middle of the calyx.

Eſſ. Ch. Calyx eight or ten-cleft. Corolla none.—Male, Filaments none; anthers in the bottom of the calyx, four-furrowed, bearded at the tip.—Female, Germens ſtalked. Nuts ſtalked, ſingle-ſeeded.

1. H. *dentata*. Linn. Suppl. 431. Forſt. Gen. t. 64. This is the only ſpecies known, and is a native of New Zealand.—A ſmooth *ſhrub*. *Leaves* alternate, oblong, ſerrated, on ſhort foot-ſtalks, very ſmooth, veins running almoſt tranſverſely. *Cluſters* axillary. *Calyx* hairy. *Nuts* very ſweet.

HEDYCHIUM, from ἡδὺς, *ſweet* or *pleaſing*, and χιων, *ſnow*, alluding to the fragrance, elegance, and whiteneſs of the flowers, at leaſt of the firſt and original ſpecies.—Kœnig in Retz. Obſ. Bot. faſc. 3. 73. Willd. Sp. Pl. v. 1. 10. Roſcoe Tr. of Linn. Soc. v. 8. 342. t. 20. f. 6. Sm. Exot. Bot. v. 2. 95. Dryandr. in Ait. Hort. Kew. ed. 2. v. 1. 3. Juſſ. 448. (Gandaſuli; Lamarck. Dict. v. 2. 603.) Claſs and order, *Monandria Monogynia*. Nat. Ord. *Scitamineæ*, Linn. *Cannæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, tubular ſheathing, membranous, ſplitting on one ſide. *Cor.* of one petal, reverſed; tube very long, cylindrical, curved; outer limb in three, equal, ſpreading, oblong, involute ſegments; inner two-lipped, the upper lip of two elliptical divaricated lobes, lower rounded, or inverſely heart-ſhaped, broadeſt, turned uppermoſt. *Stam.* Filament one, reverſed, declining, ſimple, linear, channelled, about as long, or longer than the corolla; anther attached by its back, direct, oblong, recurved, of two linear marginal lobes, meeting round the ſtyle, burſting at their outer edge. *Piſt.* Germen inferior, ſmall, roundiſh; ſtyle thread-ſhaped, embraced by the filament; ſtigma obtuſe, concave, fringed, projecting a little beyond the anther. *Peric* . . . . .

Eſſ. Ch. Anther two-lobed, recurved, terminal, embracing the ſtyle, without any appendage. Outer limb of the corolla in three equal linear lobes; inner in three parts, two-lipped. Flower reverſed. Tube longer than the limb.

1. *H. coronarium*. Sweet-ſcented Garland-flower. Curt Mag. t. 708. Sm. Exot. Bot. t. 107. (Gandaſulium; Rumph. Amb. v. 5. 175. t. 69. f. 3.)—Leaves leanceolate. Bracteas imbricated, elliptical. Lip cloven.—Native of the Eaſt Indies, where alſo it is very generally cultivated for ornament. The Malay women decorate their heads with the flowers, which they uſe alſo emblematically, according to the oriental manners, ſending them to any young man whom they wiſh to reproach with inconſtancy in love, perhaps becauſe the duration of each flower is ſo very tranſient. Dr. Buchanan found this plant, or at leaſt a pale yellowiſh variety of it, wild about the borders of fields among the elevated mountains of Upper Nepal, a country rich in the moſt beautiful and uncommon vegetable productions. In our ſtoves it is now not uncommon, blooming in autumn, and is not difficult of cultivation. The *root* is perennial, fleſhy, producing many offsets. *Stem* ſimple, leafy, three feet high, herbaceous, ſmooth. *Leaves* ſpreading in two rows, alternate, lanceolate, pointed, a foot long, downy or ſilky beneath; their footſtalks claſping the ſtem, and each crowned with an oblong ſtipula. *Spike* terminal, erect, many-flowered. *Bracteas* large, cloſely imbricated, elliptical, obtuſe, hairy at their points. *Flowers* two, three, or four to each bractea, large, pure white, with more or leſs yellow on the diſk of their broadeſt ſegment, and in Nepal they are all over yellowiſh; yet we can find no reaſon to ſuſpect any ſpecific difference. They are very ſweet-ſcented. The *fruit* is unknown, the plant being ſaid never to produce ſeed, even in Indian gardens, probably as it increaſes ſo much by root. The Nawars, or primæval inhabitants of Nepal, call this flower *Lutiſu Swa* in their language.

2. H. *ellipticum*. Broad-leaved Garland-flower.—Leaves elliptical, ſmooth. Bracteas imbricated, elliptical. Lip entire.—Gathered by Dr. Buchanan, July 26, 1802, at Narainhetty, in Upper Nepal, where it grows about the borders of fields among the mountains. No other botaniſt has ever obſerved this ſpecies, which would be as deſirable an acquiſition to our gardens as the foregoing. The *root* is fleſhy, perennial, encreaſing much. *Stem* two feet high, compreſſed, erect, covered with the long ſheathing foot-ſtalks. *Leaves* in two ranks, ſix or eight inches long, broadly elliptical, pointed, ſmooth on both ſides. *Spike* terminal, drooping, of numerous, denſe, ſomewhat level-topped, whitiſh *flowers*, one only to each *bractea*, whoſe lip is rather rounded and undivided than heart-ſhaped, and whoſe filament and ſtyle are longer than in *H. coronarium*. The tube alſo of each flower is longer and more expoſed.—This ſpecies, according to Dr. Buchanan, ſerves as commonly for ornament as the former in its native country, where it is called *Tocucha Swa*.

3. H. *ſpicatum*. Long-ſpiked Garland-flower.—Leaves lanceolate. Spike elongated. Bracteas convoluted, ſingle-flowered. Stamen much ſhorter than the lip.—Native of the borders of fields, among the hills of Upper Nepal, where it is called *Wohatty Swa*, and admired for its beauty and fragrance, the latter being, according to Dr. Buchanan, of a very powerful kind. Its habit is rather moſt like the firſt, the *ſtem* being three feet high, and *leaves* lanceolate, pale and ſomewhat ſilky beneath. But the inflorescence is totally different, conſiſting of a long, ſlender, curved *ſpike*, a foot in length, yet not riſing above the top leaf. The *flowers* as they expand become diſtant, each enveloped at the baſe by its own ſheathing, convoluted, obtuſe *bractea*, which, however, is ſhorter than the calyx. The *corolla* is white; two ſegments of the inner limb linear and widely ſpreading, the third, or lip, deeply divided or obcordate, with a claw which exceeds in length the unuſually ſhort and inflexed filament and ſtyle.

4. H. *thyrſiforme*. Denſe-ſpiked Garland-flowers.—Leaves elliptic-lanceolate. Spike ovate, denſe. Bracteas convoluted. Stamen longer than the corolla.—Gathered by Dr. Buchanan in Auguſt 1802, at Narainhetty, in Upper Nepal, with the laſt, from which the natives do not by name diſtinguiſh it. It differs, however, in its much ſhorter and very denſe *ſpike*, and long *ſtamen* and *ſtyle*. The *calyx*, moreover,

over, has three teeth, and the lip of the *flower* is finely toothed. The *leaves* too, in our ſpecimens, are ſhorter, and conſequently of a broader proportion. In other reſpects the plants agree.

5. H. *coccineum*. Scarlet Garland-flower.—Leaves lanceolate, ſmooth. Spike elongated, cylindrical. Bracteas convoluted, many-flowered. Stamen very long.—Native of the woods of Upper Nepal, where it is known by the name of *Gunculo Swa*. Dr. Buchanan gathered our ſpecimen at Suembu, June 8, 1802.—The *root* is perennial, fleſhy, lobed, and proliferous, as in the reſt of the ſpecies. *Stem* erect, leafy, ſix feet high. *Leaves* twelve or eighteen inches long, lanceolate, pointed, ſmooth on both ſides, with long, ſheathing, carinated ſtalks. *Spike* terminal, erect, long, but not ſurmounting the leaves, cylindrical, many-flowered; its common ſtalk hexagonal and downy. *Bracteas* generally three together in whorls, except a few of the upper and lower ones, an inch long, horizontally ſpreading, elliptical, obtuſe, convoluted, rather hairy and ſomewhat coloured. *Flowers* three or four to each bractea, large, ſcarlet. Outer ſegments of their limb lax and twiſted, two of the inner lanceolate and blunt, the third, or lip, very broad but ſhort, roundiſh, two-lobed, ſupported by a claw. *Stamen* much exceeding the corolla, rigid, and prominent.—Dr. Buchanan obſerved what he conceived to be a variety of this fine ſpecies, chiefly differing in its more denſe imbricated ſpike, and orange-coloured inner ſegments of the flowers. Its flower-ſtalk indeed was ſmooth, and calyx terminating in two teeth. We have ſeen no ſpecimen of this, but are inclined to preſume it may be a diſtinct ſpecies. S.

HEDYCOME, in the *Ancient Muſic*, a dancing air for the flute.

HEDYCREA, in *Botany*, is derived from ἡδυς, *ſweet*, and κρεας, *fleſh*, becauſe the pulp of its fruit is ſweet.—Schreb. 160. Mart. Mill. Dict. v. 2. (Licania; Aublet Guian. v. 1. 119. Juſſ. 340. Lamarck Illuſtr. t. 122.) Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Pomaceæ*, Linn. *Roſaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, hemiſpherical, with five acute, ſpreading teeth. *Cor.* none. *Stam.* Filaments five, inſerted into a ring ſurrounding the mouth of the calyx, oppoſite to, and ſhorter than the teeth; anthers roundiſh. *Piſt.* Germen ſuperior, roundiſh, woolly; ſtyle longer than the calyx, briſtly, woolly; ſtigma obtuſe. *Peric.* Drupa oval, ſoft, internally fibrous, of one cell. *Seed.* Nut ovate, covered with fibres, of one cell, with a hard ſhell.

Eſſ. Ch. Calyx inferior, hemiſpherical, five-toothed. Petals none. Drupa with an oval nut, encompaſſed with fibres.

1. *H. incana*. Mart. Mill. Dict. v. 2. (Licania incana; Aublet. Guian. t. 45.)—This is the only ſpecies known. It is a native of Guiana, and flowers in Auguſt; its fruit, which is called *Caligni* by the natives, ripens in October.—This *tree* riſes to the height of four or five feet, having an aſh-coloured *bark*. *Wood* hard and whitiſh, with a ſmell like rancid oil. *Leaves* alternate, ſomewhat ſeſſile, ovate, pointed, entire; green above; white beneath. *Stipulas* oblong, narrow, acute. *Flowers* ſeſſile, with two bracteas at their baſe, in axillary and terminal *ſpikes*. *Drupa* white, marked with red dots, eatable.

HEDYOSMUM, a name adopted by Swartz, from ἡδυοσμος of Dioſcorides, ſo called by the Greeks from ἡδυς, *ſweet*, and οσμη, *ſmell*, becauſe the plant was of a ſweet favour. The ancient plant appears to have been Mint. Swartz. Ind. Occ. v. 2. 957. Schreb. 650. Willd. Sp. Pl. v. 4. 476. Mart. Mill. Dict. v. 2.—Claſs and order, *Monœcia Polyandria*. Nat. Ord. *Amentaceæ*, Linn. et Juſſ.

Gen. Ch. Male, *Cal.* Catkin without ſcales, covered all over with ſtamens; perianth none. *Cor.* none. *Stam.* Filaments none; anthers numerous, heaped together in rows, erect, oblong, pointed at the top, converging at the baſe into an oblong catkin, inſerted into a linear receptacle.—Female, *Cal.* Perianth of one leaf, covering the germen, three-toothed at the top; teeth minute, erect. *Cor.* none. *Piſt.* Germen oblong, triangular; ſtyle very ſhort, three-ſided; ſtigma ſimple, obtuſe. *Peric.* Drupa roundiſh, with three ſlight angles, ſmall, ſuperior. *Seed* ſolitary, hard, three-cornered, ſhining.

Eſſ. Ch. Male, Catkin naked. Calyx none. Corolla none. Anthers imbricated.—Female, Calyx three-toothed. Corolla none. Drupa triangular, ſingle-ſeeded.

Obſ. Swartz has remarked that the female flowers of *H. arboreſcens* are found copiouſly in Auguſt, but the males he fought for in vain, and hence ſuſpects that the plant is dicecious.

1. *H. nutans*. Swartz. Ind. Occ. v. 2. 959.—"Stem ſhrubby, branches ſcattered, leaves lanceolate, pointed."—A native of the woods on the higheſt mountains of Jamaica, flowering throughout the year. The whole plant has a grateful ſmell, and a warm aromatic taſte. It is about five feet high. *Branches* ſquare, ſmooth. *Leaves* oppoſite, on ſhort footſtalks, ſerrated.

2. *H. arboreſcens*. Swartz. Ind. Occ. v. 2. 961.—"Stem arboreſcent. Branches ſtiff, erect. Leaves ovato-lanceolate."—Grows on the high mountains in the ſouth part of Jamaica. The freſh plant has an aromatic taſte and ſmell.

HEDYOTIS, a name given by Linnæus, and, as he informs us in his *Philoſophia Botanica*, derived from ἡδυς, *ſweet* or *pleaſant*, and ους, ωτος, *an ear*. But its application is founded in miſtake. Linnæus believed his *Hedyotis Auricularia* to be the fragrant herb *Auricularia*, more juſtly referred in Dale's *Pharmacologia*, 160, though with ſome prepoſterous European ſynonyms, to the genus *Mentha*, and ſaid to be very efficacious in deafneſs. This is, in fact, the *Mentha Auricularia*, Linn. Mant. 81. Willd. Sp. Pl. v. 3. 74, and by its habit and flavour appears really to be a Mint, with ſpiked flowers. The genus to which the name *Hedyotis* remains, and of which we are now to treat, cannot contend with it in ſweetneſs, nor, we preſume, in the marvellous virtue of curing deafneſs, being one of an inſipid and generally inactive tribe, except as diuretics. To this genus the original one of *Oldenlandia* muſt be united, for reaſons more particularly mentioned below.—Linn. Gen. 49. Schreb. 66. Willd. Sp. Pl. v. 1. 564. Mart. Mill. Dict. v. 2. Juſſ. 198. Lamarck. Dict. v. 3. 78. Illuſtr. t. 62. Gærtn. t. 30. (Oldenlandia; Linn. Gen. 61. Plum. Gen. 42. t. 36. Schreb. 83. Willd. Sp. Pl. v. 1. 674. Mart. Mill. Dict. v. 3. Juſſ. 198. Lamarck. Dict. v. 4. 531. Illuſtr. t. 61. Gærtn. t. 30. Dryandr. in Ait. Hort Kew. ed. 2. v. 1. 265, and in Roxb. Corom. v. 1. 2.)—Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Stellatæ*, Linn. *Rubiaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, ſuperior, permanent, in four deep, acute ſegments, broad at their baſe. *Cor.* of one petal, funnel-ſhaped, longer than the calyx; tube various in length; limb in four ſpreading, nearly equal, ſegments. *Stam.* Filaments four, awl-ſhaped, inſerted into the tube, alternate with the ſegments; anthers roundiſh. *Piſt.* Germen roundiſh, inferior; ſtyle thread-ſhaped, as long as the ſtamens, cloven; ſtigmas two, thickiſh. *Peric.* Capſule twin-globular, of two cells, opening within the crown-like calyx, by a tranſverſe cleft. *Seeds* few, angular.

Eſſ. Ch. Corolla of one funnel-ſhaped petal, four-cleft. Capſule inferior, of two cells, with ſeveral ſeeds.

Obſ.

Obſ. There has long been great ambiguity between the genera of *Hedyotis* and *Oldenlandia*, but Linnæus having, in the tenth and all following editions of the *Syſtema Naturæ* (or *Syſt. Vegetabilium*), attributed to the latter a corolla of four petals, that mark has been preſumed authentic. But it ſeems to have been adopted from Plumier, who, as being of the Tournefortian ſchool, might on this point at leaſt be expected to have obſerved faithfully; yet an examination of the ſpecies from which he took his generic character and figure, *Oldenlandia corymboſa*, proves him in the wrong. It is in vain that we look for any real difference of fruit, even in the excellent Gærtner, who, though he keeps them diſtinct, properly deſcribes the corolla of each as monopetalous. Schreber adviſes their union in his *Gen. Pl.* 820, and Lamarck, though he had previouſly deſcribed and figured them as diſtinct, finally, in the letter-preſs to his plates, ſinks *Oldenlandia* in *Hedyotis*.

But though this meaſure, which we ſhall adopt, is correct with reſpect to the original *Oldenlandiæ*, ſome ſpecies have been forced into that genus of late, unobſerved by any body, which do not really belong to it. Theſe are *O. digyna* and *pentandra* of Retzius and Willdenow, which have five petals, five ſtamens, and a five-cleft calyx, with perhaps two ſtyles, and conſtitute a very good genus, with which the name of *Oldenlandia* ought now to remain. Whether *O. depreſſa* of Willdenow be in the ſame predicament, we cannot decide, having ſeen no authentic ſpecimen; but we have an Eaſt Indian plant which nearly agrees with this deſcription, and is of the ſame genus with the two ſpecies juſt named. We now proceed to arrange the ſpecies of *Hedyotis*, thus augmented with what have been conceived *Oldenlandiæ*, as well as with ſome hitherto non-deſcript, according to their natural affinities.

1. H. *fruticoſa*. Linn. Sp. Pl. 147. (Valerianella foliis nervoſis acutis, floſculis in caulium ſummo quaſi umbellatis; Herm. Zeyl. 227. t. 107.)—Leaves ovato-lanceolate. Umbels aggregate, corymboſe, ſtalked, terminal and axillary.—Native of Ceylon, where it is called *Waeranya*. The *ſtem* is ſhrubby, knotty, round, much branched. *Branches* oppoſite, quadrangular when young, leafy and finely downy. *Leaves* oppoſite, ſtalked, from one to three inches long, more or leſs ovate, pointed, entire, roughiſh, ſtrongly ribbed; paler beneath. *Footſtalks* ſhort, thick and downy, connected by a pair of ſhort broad *ſtipulas*, which are each crowned with three or four long linear hairy teeth. *Flower-ſtalks* about the ends of the branches, axillary and terminal, ſhorter than the leaves, angular, downy, each bearing ſeveral deaſe downy *umbels*, and a pair or two of narrow oblong *bracteas*. The *germen* and *calyx* are downy; the latter recurved. *Corolla* many times longer than the calyx, apparently reddiſh or blueiſh, denſely bearded with white briſtles on its inſide, its ſegments long and revolute. Burmann's figure gives a wrong idea of the ſtipulas, and is not otherwiſe very characteriſtic.—We have formerly received from the Eaſt Indies, for *H. fruticoſa*, what turns out to be *Knoxia corymboſa* of Willdenow, v. 1. 582. Lamarck having never, as he ſuppoſed, ſeen this firſt ſpecies of *Hedyotis*, has, if we miſtake not, deſcribed it over again by the name of *paniculata*.

2. H. *Auricularia*. Linn. Sp. Pl. 147. (Valerianella paluſtris, foliis nervoſis oblongis, floſculis ad caulium nodos, inter foliorum finas, collectis; Burm. Zeyl. 227. t. 108. f. 1. Marigati; Rheede Mal. v. 10. 63. t. 32.)—Leaves elliptic-lanceolate, even, ſmoothiſh. Stem downy. Flowers denſely whorled.—Native of Ceylon and other parts of the Eaſt Indies, in ſandy ground. *Root* ſimple, pleaſantly ſcented, ſaid to be perennial. *Stems* ſeveral, proſtrate, but little branched, about a foot long, leafy, round, finely downy. *Leaves* an inch and half or two inches long, elliptic-lanceolate, ſometimes ovate, acute, entire, flat and even though ribbed; ſmooth and rather ſhining above; paler and often roughiſh beneath. *Footſtalks* half an inch long, nearly ſmooth, connected with a pair of finely downy ſheathing *ſtipulas*, crowned with ſeveral long, narrow, briſtle-like points. *Flowers* white, numerous, in denſe ſeſſile axillary tufts, being as truly whorled as in moſt plants with only oppoſite leaves. Their *calyx* and *germen* are nearly or quite ſmooth.

This ſpecies is confounded, in the *Materia Medica* and *Flora Zeylanica* of Linnæus, with *Mentha Auricularia*, as we have already ſaid. Yet, according to Rheede, it is not altogether uſeleſs in medicine, the bruiſed leaves, mixed with butter, ſerving to bring abſceſſes to maturity.

It does not appear that Lamarck's *H. nervoſa* is more than a variety of this, though he deſcribes the leaves as agreeing nearly with the following, than which nothing can be more unqueſtionably diſtinct from *H. Auricularia*.

3. H. *capitata*. Lamarck. Dict. v. 3. 80.—Leaves lanceolate, pointed, ſtrongly ribbed, hairy. Branches rough with deflexed hairs. Flowers in axillary, ſtalked, ſolitary tufts.—Native of Tranquebar. Remarkable for the reflexed ſhaggy hairs of the *branches*, which, in the dried plant at leaſt, are of a tawny or golden hue. The *leaves* are much narrower, and more pointed than in the preceding, hairy, deeply furrowed along the ſide nerves, or, in a manner, plaited. *Footſtalks* and *ſtipulas* very hairy. *Flowers* very ſmall, in little, round, hairy, axillary, ſtalked, ſolitary, alternate tufts or heads, and not by any means whorled. This character leaves us no doubt as to Lamarck's plant being the ſame with ours, though his ſpecimens ſeem to have been leſs hairy. Had he illuſtrated the genus by a figure of this, inſtead of copying Burmann's bad plate of the firſt ſpecies, which appears to have led him aſtray reſpecting that plant, he would have rendered a ſervice to botany.

4. H. *hiſpida*. Retz. Obſ. faſc. 4. 23. Willd. n. 4.—Leaves linear-lanceolate, briſtly on both ſides. Flowers whorled.—Native of China, near Canton. *Stems* ſix inches long, nearly ſimple, decumbent, ſquare, hiſpid. *Leaves* ſtalked, pointed, entire, hiſpid on both ſides. *Footſtalks* extremely hiſpid, united into a ſhort ſheath with the *ſtipulas*, which are torn into narrow ſegments. *Flowers* nearly ſeſſile, whorled. *Calyx* hiſpid. The deſcription of the parts of fructification agree with the generic character. We have no ſpecimen.

5. H. *verticillata*. (Oldenlandia verticillata; Linn. Mant. 40. Crateogonum minus, ſeu verum; Rumph. Amb. v. 6. 25.)—Leaves linear-lanceolate, ſmooth on both ſides. Flowers whorled. Calyx and angles of the ſtem minutely briſtly.—Native of open hills in Amboyna and Java. *Root* creeping. *Stems* ſeveral, about a foot long, weak or decumbent, leafy, quadrangular, the angles rough, with minute, crowded, prominent, rigid, ſhort briſtles, as are alſo the very ſharp ſegments of the *calyx*. *Leaves* numerous, croſſing each other in pairs, ſpreading, above an inch long, acute, narrow, entire, ſomewhat revolute, ſmooth on both ſides, very pale at the back. *Footſtalks* very ſhort. *Teeth* of the ſtipulas long and capillary. *Whorls* denſe, the upper ones of but few flowers. *Corolla* white.—Rumphius's *Crateogonum majus*, v. 6. t. 10, confounded with the above in Linnæus's quotation, appears to be a *Spermacoce*, by the deſcription of the fruit.

6. H. *trinervis*. (Oldenlandia trinervia; Retz. Obſ. faſc. 4. 23. Willd. n. 3.)—Leaves ovate, three-ribbed, ſomewhat fringed. Flowers axillary, ſolitary or in pairs. Fruit hairy. Calyx minute.—Native of the Eaſt Indies. Koenig gathered it in ſhady ſloping ſituations, where the

foil

ſoil is ſandy and wet, eſpecially under *Pandanus* trees. Dr. Rottler ſent what we deem the ſame, from rice-fields at Tranquebar, by the name of *O. orbiculata*. The *root* is ſlender and fibrous, apparently annual. *Stems* ſeveral, proſtrate, three or four inches long, branched, leafy, angular, ſlightly hairy. *Leaves* oppoſite, on ſhort hairy ſtalks, ovate, obtuſe, entire, ſmooth on both ſides, but more or leſs fringed at the edges, marked with two ſide-ribs in their lower part. *Stipulas* ſmall, fringed. *Flowers* one, or at moſt two, from the boſom of each leaf, on ſhort ſtalks. *Fruit* very hairy, pale. *Calyx-teeth* very ſmall.

7. H. *uniflora*. Lam. Illuſtr. 271. (Oldenlandia uniflora; Linn. Sp. Pl. 174. O. calycibus fructuum maximis coloratis; Gron. Virg. ed. 1. 138. ed. 2. 21. Alſine aquatica major repens, foliis acuminatis, virginiana; Pluk. Phyt. t. 74. f. 5.)—Leaves ovate, acute, rough-edged. Flowers axillary, ſolitary or in pairs. Fruit hairy, ſhorter than the calyx.—Native of Virginia, and, according to Browne, of Jamaica. The *ſtems* are much longer, and more branched, than in the laſt. *Leaves* more acute, longer, yet not an inch in length, ſcarcely three-ribbed, ſmooth, except that their edges and midrib are rough with minute briſtly hairs. *Germen* hairy, ſhorter than either the flower-ſtalk or ſegments of the *calyx*, the latter being unuſually large, ovate, acute, green, but little expanded, ſmooth, ſlightly fringed.

8. H. *hirſuta*. (Oldenlandia hirſuta; Linn. Suppl. 127.)—Leaves ovate, ſomewhat heart-ſhaped, ſtalked, hairy. Umbels axillary, ſolitary, ſtalked, of few flowers. Fruit hairy.—Gathered in Java by Thunberg. *Root* creeping. *Stems* proſtrate, nearly ſimple, hairy, three or four inches long. *Leaves* ſtalked, broad-ovate, or rather heart-ſhaped, acute, beſprinkled with ſoft hairs. *Stipulas* membranous, fringed. *Umbels* few, axillary, ſolitary, hairy, of very few flowers, their ſtalk not half the length of the leaf. *Fruit* turgid, hairy, longer than the lanceolate acute ſegments of the *calyx*. This herb, except being ſlightly hairy, bears a conſiderable reſemblance to the ſtem and leaves of our pretty *Lyſimachia nemorum*. It is nearly related to the two laſt, though all three are abundantly diſtinct.—H. *hirſuta*. Lamarck. Illuſtr. 270. is not this, but, as we preſume, our H. *auricularia*.

9. H. *debilis*. (Oldenlandia debilis; Forſt. Prodr. 10.)—"Leaves ovate, ſeſſile. Umbels axillary, ſtalked, of few flowers."—Gathered by Forſter in the iſland of Tongatabu, in the South Seas. We have no ſpecimen, nor any further information concerning this ſpecies.

10. H. *fœtida*. (Oldenlandia fœtida; Forſt. Prodr. 10.)—Leaves elliptical, thin, ſmooth. Panicle three-forked, terminal, ſpreading. Corolla ſmooth. Stipulas with a ſimple point, naked.—Gathered by Forſter in Tongatabu and Otaheite. The *ſtem* is rather ſhrubby. Whole *plant* ſmooth, turning black in drying. Young *branches* ſquare. *Leaves* ſtalked, oppoſite, an inch or inch and half long, elliptical, entire, flat, thin and ſmooth. *Stipulas* forming a ring within the footſtalks, permanent, ſhort, each tipped with a ſhort thick point, but not fringed. *Panicle* terminal, ſpreading, of three principal branches, each ſubdivided repeatedly in a three-fold manner, the central branch always ſhorteſt, affording a true idea of a trichotomous panicle. *Bracteas* ſmall, oppoſite, acute, in pairs under each ſubdiviſion. *Germen* and *fruit* ſhort or depreſſed; *calyx* ſtill ſhorter, recurved. *Corolla* much longer than the calyx, its tube cylindrical and ſmooth. The *ſtigma* in the only flower we can examine is capitate, but ſeems ſlightly two-lobed.—The habit of the plant is greatly at variance with all the foregoing.

11. H. *coriacea*.—Leaves elliptical, coriaceous, ſmooth. Panicle three-forked, terminal, denſe. Corolla externally downy. Stipulas with a ſimple point, naked.—Gathered in the Sandwich iſlands by Mr. Menzies, to whom we are indebted for a ſpecimen. It agrees in aſpect, ſhrubby habit, ſtipulas, and black hue when dried, with the laſt; but the *leaves* are larger, and remarkably coriaceous; *panicle* more denſe; *flowers* much larger, their tube club-ſhaped, near half an inch long, externally downy, the ſegments of the limb ſtrongly deflexed, with long, taper, recurved points. The *calyx*, *ſtalks*, and *germen* are downy. This ſpecies and the laſt appear more akin to the *Bouvardia*, Saliſ. Parad. t. 88. Dryandr. in Ait. Hort. Kew. ed. 2. v. 1. 245, than to the genuine ſpecies of *Hedyotis*, but we have not their fruit to decide this queſtion; and the following one, agreeing with them in ſtipulas and habit, ſeems without violence to connect them with the reſt.

12. H. *racemoſa*. Willd. n. 2. Lamarck. Dict. v. 3. 80. Illuſtr. 270. t. 62. f. 2. (Oldenlandia paniculata; Linn. Sp. Pl. 1667. Burm. Ind. 38. t. 15. f. 1. Tsjeru-talu-dama; Rheede Mal. v. 10. 49 t. 25?)—Leaves elliptic-oblong, thin, ſmooth. Flower-ſtalks partly umbellate, panicled, terminal. Stipulas pointed, ſomewhat toothed.—Native of ſandy ground in the Eaſt Indies. *Stem* rather woody, various in height, much branched and forked repeatedly; the *branches* quadrangular, leafy, ſmooth. *Leaves* elliptic-oblong, or ovate, ſtalked, ſmooth, or very finely downy, thin and even like thoſe of H. *fœtida*, with which they agree in ſize and ſhape. The *ſtipulas* alſo are like thoſe of the two foregoing, but beſides the central point of each, there are ſometimes a few ſmaller teeth. *Flowers* in ſeveral naked, panicled, terminal, or partly axillary, umbels or cluſters, ſmall, blueiſh, their corolla with a tube of moderate length, ſmooth. The *Hortus Malabaricus* deſcribes the ſeeds as only two in each capſule, which, if right, proves that ſynonym to be erroneous, our plant having, as it ought, numerous ſmall ſeeds; yet the figure and deſcription agree with it in every other point. Lamarck's deſcription alſo anſwers to our plant, but not at all to the figure of Plukenet, to which he refers in a parentheſis, t. 454. f. 2, and which is evidently the *Knoxia corymboſa* of Willdenow, mentioned under our firſt ſpecies; a genus with two ſeeds only to each flower.

13. H. *pumila*. Linn. Suppl. 119.—Leaves ovate, acute, rough-edged. Flower-ſtalks ſimple, axillary, alternate. Fruit oval. Gathered by Koenig in dry, barren places, or on walls, at Tranquebar. *Root* fibrous, annual. *Herb* ſomewhat like *Anagallis arvenſis*, ſcarcely a ſpan high, branched from the baſe, ſmooth in its general appearance, but the edges of the *leaves* and *calyx* are found rough when magnified. *Stipulas* membranous, pointed and fringed. *Flower-ſtalks* rather ſhorter than the leaves, erect, capillary, naked, ſmooth, ſingle-flowered. *Corolla* whitiſh, ſmall. *Capſule* elliptical, ſhining, beſprinkled with a few white, cloſe-preſſed hairs, its length exceeding that of the *calyx*, which is pointed and ſlightly ſpreading.

14. H. *diffuſa*. Willd. n. 7.—Leaves lanceolate, acute, rough-edged. Flower-ſtalks ſimple, axillary, alternate. Fruit nearly globoſe. Stem procumbent.—Native of the Eaſt Indies. *Stem* round, procumbent, diffuſe, very long, with oppoſite branches. *Leaves* nearly an inch in length, ſtalked, lanceolate, narrow, acute, ſmooth, roughiſh at the edge. *Flowers* axillary, ſolitary, ſtalked, the length of the leaf-ſtalks. *Corolla* funnel-ſhaped. *Capſule* nearly globoſe, crowned with the calyx. We know this only by Willdenow's deſcription.

15. H. *biflora*. Lamarck. Illuſtr. 272. (Oldenlandia biflora; Linn. Sp. Pl. 174. Antirrhinum humile anguſtifolium, floſculo gemello, ex alis foliorum producto; Burm. Zeyl. 22. t. 11.)—Leaves lanceolate, acute, rough-edged. Flower-ſtalks axillary, alternate, two-flowered.—Native of the

the Eaſt Indies. *Root* long, fibrous, apparently annual. *Stem* branched from the bottom, a ſpan high, leafy, angular, often rough-edged. *Leaves* an inch long or more, ſomewhat ſtalked, lanceolate, narrow, acute, ſmooth except about the edges, pale beneath. *Stipulas* membranous, fringed with a few ſlender teeth. *Flower-ſtalks* rather ſpreading, capillary, ſmooth, pale, ſhorter than the leaves, ſolitary, divided not half way down, each bearing two ſmall *flowers*, whoſe corolla, according to Burmann's account, is reddiſh and two-lipped, yet nothing can be more certain than that the calyx and fruit are thoſe of an *Hedyotis*, cloſely agreeing with thoſe of H. *pumila*, except the capſule being more round and leſs oval.—The diviſion of the flower-ſtalks in this ſpecies is not ſo conſtant as could be wiſhed. We have on the ſame ſpecimen ſome as above deſcribed, with others quite ſimple and ſingle-flowered; and the latter are either ſolitary or in pairs, or even three together, from the ſame leaf. Such is a ſpecimen which Linnæus, in his herbarium, confounded with his own *Oldenlandia umbellata*, hereafter deſcribed; but he does not ſeem to have adverted to this ſpecimen in any of his works, nor is the ſpecific character taken from it.

16. H. *graminifolia*. Linn. Suppl. 119. Vahl. Symb. faſc. 2. 27. (H. herbacea; Forſk. Arab. fel. 105. Oldenlandia ſtricta; Linn. Mant. 200. Alſine ſpergulæ foliis, capitulis brevioribus duris; Pluk, Mant. 9. t. 332. f. 2.) —Leaves linear-lanceolate, acute, roughiſh. Stem weak. Panicle cloven, racemoſe. Stipulas pointleſs, entire, membranous.—Native of Malabar, where, according to Plukenet, it is called *Arraveenampoondo;* we have it alſo from Tranquebar. The figure in Plukenet is very bad, but we know of no other. Linnæus deſcribed this plant twice over by mere inattention. It is ſufficiently diſtinguiſhable by its weak ſpreading *ſtems*, and narrow *leaves* about an inch and half long, but eſpecially by its inflorescence, which conſiſts of panicled cluſters, forked at their baſe. The *corolla* is purpliſh, exactly funnel-ſhaped. *Stigmas* capitate, diſtant. *Capſule* elliptic-oblong, ſmooth. Segments of the *calyx* ſhort, triangular, erect. The habit of this ſpecies is like ſomething between an *Aſperula* and a *Stellaria*.

17. H. *ſerpylloides*. Lamarck. Illuſtr. 271.—"Leaves ovate. Stipulas fringed. Flowers in denſe, ſeſſile, terminal cluſters."—Gathered in Guadaloupe by M. Richard. The *ſtems* are diffuſe, five or ſix inches long.—Such is Lamarck's ſhort account, in the letter-preſs of his *Illuſtrations*, which is all the information we have concerning this ſpecies, but the inflorescence appears to mark it as ſufficiently diſtinct.

18. H. *capenſis*. Lamarck. Illuſtr. 271. (Oldenlandia capenſis; Linn. Suppl. 127. Thunb. Prodr. 29.)—Leaves linear-lanceolate, acute, revolute, rough. Stems decumbent, rough-edged. Flower-ſtalks ſimple, axillary, alternate. Calyx fringed, nearly as long as the ſhort angular fruit.—Gathered by Thunberg at the Cape of Good Hope, and by Commerſon in the iſle of Bourbon. The *ſtems* are about a ſpan long, branched, ſquare, with rough angles. *Leaves* ſomewhat ſtalked, hardly an inch long, revolute and often recurved, their upper ſide, and their midrib beneath, more or leſs rough with minute briſtles, like a *Galium*. *Stipulas* membranous, pointed and ſomewhat fringed. *Flower-ſtalks* always ſhorter than the leaves, ſometimes very much ſo, thickiſh, ſpreading, angular. Tube of the *corolla* cylindrical, narrow, ſcarcely ſo long as the *calyx;* limb ſhort and obtuſe. Segments of the *calyx* ſpreading or recurved, triangular, keeled, fringed with briſtles, about equal in length to the ſhort roundiſh *fruit*, which is ſmooth, marked with four ribs running down from the keels of the calyx. The *flowers* are white. We preſume this muſt be diſtinct from the *diffuſa*, n. 14, as Willdenow expreſſes his having ſeen both; otherwiſe their deſcriptions might ſeem to be hardly ſufficiently clear of each other.

19. H. *tenuifolia*. (Oldenlandia tenuifolia; Forſt. Prodr. 11, but not of Burmann.)—Leaves linear-lanceolate, revolute, ſmooth, as well as the ſtem. Flower-ſtalks ſimple, axillary, alternate. Calyx ſmooth, recurved, keeled, as long as the fruit.—Gathered by Forſter in the iſle of Tanna, but we cannot aſſent to the ſynonym he has applied to it of Burmann, though, as the latter really belongs to *H. herbacea*, the name may remain with Forſter's plant, as we have left it. This is a larger ſpecies than the laſt, with very long trailing branched *ſtems*, and every part is nearly or quite ſmooth. The *leaves* are an inch long, very acute, narrow and revolute. *Flower-ſtalks* ſcarcely half that length, ſpreading, thick and firm. *Fruit* ſmooth, roundiſh, depreſſed, ſlightly ribbed from the decurrent keels of the broad and ſtrong ſegments of the *calyx*, which are about its length, recurved, ſmooth-edged, or now and then perhaps very ſlightly toothed.

20. H. *herbacea*. Linn. Sp. Pl. 147. Meerb. Ic. t. 2. (Oldenlandia tenuifolia; Burm. Ind. 37. t. 14. f. 1. Parpadagam; Rheed. Mal. v. 10. 69. t. 35.—*β* Schanganampuliu; ibid. 45. t. 23.)—Leaves linear-lanceolate, ſmooth. Stem very much branched, forked. Flower-ſtalks in pairs, ſimple. Fruit globoſe, with four furrows. Calyx erect, minute.—Native of various parts of the Eaſt Indies, in ſandy ground. The *root* appears to be annual, though ſometimes ſtrong and almoſt woody, tapering, branched, fibrous, with a ſimple crown. *Stem* ſolitary, 11 or 12 inches high, very much branched from the very bottom, repeatedly forked, buſhy, leafy, quadrangular, ſmooth, with rather ſwelling joints, which are often bent or zigzag. *Leaves* about an inch long, lanceolate, ſometimes nearly linear, acute, entire, flat, ſmooth in every part, paler beneath, ſomewhat ſtalked. *Stipulas* extremely ſhort, entire and beardleſs. *Flower-ſtalks* in pairs from the forks of the ſtem, ſpreading, capillary, ſmooth, ſimple and ſingle-flowered; ſhorter than the full-ſized leaves; longer than the ſmaller upper ones. *Flowers* very diminutive, their *corolla* white, long and ſlender. *Fruit* pale brown, ſmooth, nearly globoſe, with four ſlight furrows running down from the ſegments of the *calyx*. The latter are ſmall, green, diſtant, erect, acute, their points on a level with the prominent valves of the capſule, by which this differs from all the foregoing.—*β* is but a ſlight, rather more buſhy, variety. The name *herbacea*, not very diſcriminative when given, is far leſs ſo as the genus now ſtands, but it would not be eaſy to find one more expreſſive, if we were allowed to change it.

21. H. *ſtricta*.—Leaves linear, revolute, ſmooth, upright. Stem erect, ſtraight, ſlightly branched. Flower-ſtalks ſolitary or in pairs. Fruit globoſe. Calyx erect, minute.—Gathered at Sierra Leone by Dr. Afzelius. This is a very ſlender, annual, ſmooth, upright ſpecies, about a foot high, akin to the laſt, except that its *leaves* are revolute and much narrower, with ſome appearance of ſerratures towards their points. *Stipulas* very ſhort, but toothed. *Flower-ſtalks* one or two from between the diminutive upper leaves, widely ſpreading, capillary, ſimple. *Flowers* white, extremely ſmall and ſlender. *Fruit* like the laſt, but ſmaller, and ſcarcely furrowed, the ſummits of its valves extending even beyond the *calyx*, whoſe teeth are very ſmall, green and triangular.

22. H. *virgata*. Willd. n. 10.—"Leaves linear. Stem erect. Panicle forked, ſtraight. Flower-ſtalks lateral, in pairs."

pairs."—Native of Guinea. *Root* woody, perennial. *Stems* feveral, ſtraight, round, ſmooth, panicled in their upper part, with forked branches. *Leaves* linear, very narrow. *Flowers* in pairs at the ſides of the branches, without leaves; their *ſtalks* unequal. *Corolla* ſlender, funnel-ſhaped. *Capſule* globoſe.—Such is Willdenow's deſcription of this ſpecies, with which we are unacquainted. It appears to be nearly related to the laſt, but the perennial root, numerous ſtems, and unequal flower-ſtalks, without leaves, are expreſſive of a real difference.

23. H. *corymboſa*. Lamarck. Illuſtr. 272. (Oldenlandia corymboſa; ibid. t. 61. Linn. Sp. Pl. 174. O. humilis hyſſopifolia; Plum. Ic. 205. t. 212. f. 1. Ehret Pict. t. 2. f. 1. and t. 4.)—Leaves linear-lanceolate. Flower-ſtalks axillary, alternate, ſomewhat corymboſe, bearing ſeveral flowers. Fruit broader than long, rather compreſſed.—Native of the Weſt Indies; we have it alſo from the iſle of Banda, gathered by the late Mr. Chriſtopher Smith. Linnæus cultivated it in the Upſal garden, and Miller at Chelſea. The *root* is ſaid to be annual, but in our Banda ſpecimen it is woody. The *ſtem* is very much branched from the very bottom, ſpreading, and partly decumbent; leafy, ſquare, ſmooth, except in ſome degree at the angles, but never between them. *Leaves* about an inch long, lanceolate, narrow, acute, ſcarcely ever quite ſmooth, ſometimes conſiderably rough on their upper ſide, pale beneath; their baſe tapering into a ſhortiſh dilated footſtalk, united on each ſide with the pale, membranous, dilated *ſtipula*, which is fringed with a few long ſlender teeth. *Flower-ſtalks* numerous, alternate, ſolitary, axillary, longer than the leaves, ſlender, ſometimes roughiſh, ſpreading, bearing three, four, or five flowers, whoſe partial ſtalks are corymboſe, not umbellate, as they never ſpring exactly from one common point. There is a minute, membranous, acute *bractea* at the baſe of each. *Flowers* ſmall, white, their *corolla* ſhort and wide in compariſon with ſeveral of the laſt deſcribed. *Fruit* very abrupt and broad at the ſummit, ſo as to be almoſt hemiſpherical, a little compreſſed, with a ſtrong furrow at each ſide, ſmooth. Segments of the *calyx* acute, a little recurved, reaching much beyond the valves. In natural affinity this ſpecies comes nearer to *biflora* perhaps than to *herbacea*, though its habit reſembles the latter.

24. H. *coarctata*.—Leaves linear. Flower-ſtalks axillary, ſolitary or aggregate, ſomewhat corymboſe, rough all over like the ſtem. Fruit contracted at the mouth.—Native of the Eaſt Indies. *Root* tapering, annual. *Stems* branched from the baſe, a foot or two in height, ſpreading, round, or very ſlightly angular, rough all over with minute prominent points, as are alſo the *flower-ſtalks*, and ſometimes the upper ſurface of the *leaves*. The latter are narrower than in H. *corymboſa*, and in ſome meaſure revolute. *Stipulas* with about three long briſtly central points. *Flower-ſtalks* either ſolitary, or two or three together at each pair of leaves, bearing one, two, or three *flowers* like thoſe of the laſt. The *fruit*, however, is eſſentially different, more globular, very much contracted at the mouth, the *calyx-teeth* triangular, moſtly erect, reaching but little beyond the valves.

25. H. *umbellata*. Lamarck. Illuſtr. 272. (Oldenlandia umbellata; Linn. Sp. Pl. 174. Fl. Zeyl. n. 67. Roxb. Coromand. v. 1, 2. t. 3. Lyſimachiæ affinis, ſatureiæ folio maderaſpatenſis, capſulis in ſummitate ferè umbellatis; Pluk. t. 119. f. 4.)—Leaves linear-lanceolate, roughiſh like the ſtem. Flower-ſtalks terminal, umbellate or corymboſe. Capſule half naked.—Native of the Eaſt Indies, in light ſandy ground near the ſea, flowering in the latter part of the wet ſeaſon, and ripening ſeed in January. *Roxburgh.* *Root* biennial, rarely triennial, very long, ſomewhat woody, with an orange-coloured bark. *Stems* numerous, a ſpan high, much branched from the very bottom, ſpreading or diffuſe; when cultivated more erect, and about a foot high; leafy, round, all over rough with prominent points like the laſt deſcribed. *Leaves* oppoſite, ſometimes three or four together, not an inch long, narrow, acute, roughiſh. *Stipulas* pale, with a few, long, narrow, membranous ſegments. *Flower-ſtalks* terminal, cluſtered, partly umbellate, partly cymoſe, all ſhort and rough, with linear *bracteas*. Segments of the *calyx* nearly erect, triangular, keeled, ſtrongly fringed, inſerted about the middle of the ripe fruit, whoſe valves project conſiderably, though not ſo far as the points of the calyx, while the ſhort lower half is ſtrongly ribbed by the decurrent keels. Theſe diſtinctive characters of the calyx and fruit are not ſhewn by Dr. Roxburgh's Indian artiſt. The *corolla* is pale purpliſh, funnel-ſhaped, about twice as long as the calyx, with a ſpreading border.—This is the moſt valuable ſpecies of the whole genus, being the Clay root, or Eaſt Indian madder, much cultivated on the coaſt of Coromandel, though the wild roots are better, when they can be got. It is uſed for giving a red colour to cotton, either by dyeing, printing, or painting. Alkaline ſubſtances, added to either a watery infuſion or ſpirituous tincture of the root, produce this colour. Very long details of various proceſſes uſed by the natives of the country are given by Dr. Roxburgh, which it is probable might be much ſhortened, and perhaps improved, by an European dyer or chemiſt. As the roots will keep good for three or four years, experiments might eaſily be made in this country, where indeed the art of giving fine red colours to cotton has of late been much advanced, but whether by means of this plant or by ſome improved management of the common madder, or other ſubſtances, it is not eaſy to determine.

The above full hiſtory of the genus *Hedyotis* would be incomplete without mention of ſome ſpecies that have been erroneouſly referred to it, or to *Oldenlandia*. Of theſe we have in the introductory part of this article, mentioned *O. digyna* and *pentandra*, as conſtituting a very diſtinct genus, which we would ſtill call *Oldenlandia*, and of which we have a third ſpecies, poſſibly *O. depreſſa* of Willdenow; but the *Nela-Tsjira*, Rheede Mal. v. 10. 61. t. 31, quoted by him as a ſynonym, appears very doubtful. This ſynonym accords tolerably well with *Hedyotis maritima*, Linn. Suppl. 119, a plant we have ſtruck out of our liſt of ſpecies, as having a ſuperior germen, and belonging, we believe, to Juſſieu's order of *Lyſimachiæ*, certainly by no means to the genus in queſtion.—*Oldenlandia repens* of Linnæus we have long ſince referred to its proper place, as a diſtinct genus; ſee DENTELLA.—*Hedyotis rupeſtris*, adopted by Willdenow from Swartz, a very ſingular Weſt Indian plant, is now referred by the latter to *Buchnera*.—*H. longiflora* of Lamarck is, as he himſelf ſuſpected, *Rondeletia piloſa* of Swartz, being one of the tetrandrous ſpecies of the latter genus. S.

HEDYPNOIS, from ἡδὺς, *ſweet*, und πνέω, *to ſmell*, is recorded by Pliny as a name ſometimes given to the wild Endive or Succory. More recent writers have varied in its application. Some conſider it as a ſynonym of the *Aphace* of Dalechampius, which is the Linnæan *Crepis teſtorum*; and hence perhaps Hudſon was led to chooſe it for a genus eſtabliſhed by himſelf, which includes, though erroneouſly, this *Crepis*. Hudſon's genus, as far as it ſeemed to the author of the *Flora Britannica* and *Engliſh Botany* a good one, is adopted in thoſe works by the ſame name; but having been called by Scopoli *Apargia*, it ſo ſtands in the works of Schreber and Willdenow, who will no doubt be followed in this meaſure. The *Hedypnois* of theſe authors is, on the other

other hand, that of Tournefort, or *Hyoſeris Hedypnois* of Linnæus, which is alſo the *Hedypnois* of Juſſieu, though he includes under it *Zacyntha* of Schreber; and of Gærtner, though the latter, by a ſtrange error, quotes under it ſynonyms of Linnæus and Plukenet that belong to *Hyoſeris radiata*. The long unſettled and wandering name of *Hedypnois* may therefore now be conſidered as fixed, though, as to the propriety of its application in any of the above caſes, we can offer nothing very ſatisfactory. All that can be ſaid for the plants that have borne it is, perhaps, that they have not ſo bad a ſmell as ſome of their relatives, and therefore may, by compariſon, be termed *ſweet;* or having little or no ſcent, notwithſtanding the fœtid tribe to which they belong, their name may be juſtified on the principle of Martial, who ſays on a ſimilar occaſion, "*benè olet qui non olet.*"—Schreb. 532. Willd. Sp. Pl. v. 3. 1616. Juſſ. 169. Tourn. t. 271. Gærtn. t. 160.—Claſs and order, *Syngeneſia Polygamia-æqualis.* Nat. Ord. *Compoſitæ ſemiflоſculoſæ*, Linn. *Cichoraceæ*, Juſſ.

Gen. Ch. *Common Calyx* cylindrical, permanent, of about ten linear, erect, acute, equal leaves, accompanied at their baſe by fewer and narrower, ſhort, cloſe-preſſed ſcales. *Cor.* compound, ſomewhat imbricated, uniform; the florets numerous, all perfect, monopetalous, ligulate, linear, abrupt, with five teeth. *Stam.* Filaments five, capillary, very ſhort; anthers united into a hollow cylinder. *Piſt.* Germen oblong; ſtyle thread-ſhaped, the length of the ſtamens; ſtigmas two, reflexed. *Peric.* none, except the common calyx hardened, cloſed, ſomewhat globoſe, its leaves entirely covering the marginal ſeeds. *Seeds* ſolitary, oblong, ſlightly incurved, ſtriated, roughiſh, about the length of the calyx; the outer row crowned with a little membranous partial calyx, which is nearly upright, cup-ſhaped, obſcurely five-ſided, minutely toothed, without any proper ſeed-down; the inner ones crowned with an obſolete little partial calyx, which is very ſhort, conſiſting of numerous briſtles, encloſing a ſeed-crown of five, nearly upright, awned ſcales. *Recept.* naked.

Eſſ. Ch. Receptacle naked. Calyx with ſcales at the baſe. Seed-crown of the diſk double; the outermoſt obſolete, of many briſtles; the inner of five chaffy ſcales: of the radius ſingle, membranous, and toothed.

1. H. *monſpelienſis*. Willd. n. 1. (Hyoſeris Hedypnois; Linn. Sp. Pl. 1138. Gouan. Fl. Monſp. 353. Hieracium facie hedypnois; Lob. Ic. 239. H. falcatum alterum; Ger. em. 299.)—Stem branched, diffuſe. Leaves oblong, ſtrongly toothed, ſeſſile, contracted towards the baſe.—Native of the ſouth of Europe. *Root* annual, ſmall. *Stem* branched from the baſe, 12 or 18 inches high, ſtraggling, round, leafy, ſmooth. *Leaves* alternate, ſeſſile, and in ſome meaſure claſping the ſtem, a little briſtly, eſpecially their ribs and edges, three or four inches long; the upper ones narrow, taper, ſmall and entire. *Flowers* ſolitary at the ends of the branches, ſmalliſh, yellow; when young drooping. *Fruit* erect. The *ſeeds* are conſpicuous for the long taper ſcales which crown the inner ones, while thoſe of the circumference bear each a little browniſh fringed cup.—The herb is ſaid to be neither bitter nor milky. We have never ſeen it alive.

2. H. *mauritanica*. Willd. n. 2.—Stem upright, branched. Leaves oblong, ſlightly toothed, ſomewhat heart-ſhaped and claſping at their baſe.—Suppoſed to be a native of Barbary. Willdenow deſcribed it from ſome botanic garden, where it was called by the name of *Hyoſeris mauritanica*. We have from Gibraltar a plant gathered there by the Abbé Durand, flowering in May, which anſwers to the deſcription, but is ſo very near the firſt ſpecies, that we can find ſcarcely any difference. The *leaves* however are certainly very minutely and ſparingly toothed, and their baſes more heart-ſhaped than in the former. The keels of the *calyx-leaves*, when in fruit, are ſpinous, but we have them full as much or more ſo in various ſpecimens of *H. monſpelienſis*.

3. H. *rhagadioloides*. Willd. n. 3. (Hyoſeris rhagadioloides; Linn. Sp. Pl. 1139. H. cretica; Cavan. Ic. v. 1. 32. t. 43.)—Stem branched, diffuſe. Leaves oblong, toothed, tapering at the baſe, ſeſſile. Calyx of the fruit hairy.—Native of the ſouth of Europe, very common about Madrid, as Loefling and Cavanilles remarked, flowering in May and June. This is more rough or hairy than the foregoing, eſpecially the *calyx*, which is all over very briſtly and hairy; the flowering branches are alſo rough, and conſiderably more ſwelling than in any other ſpecies. The ſize of the teeth of the *leaves* is very variable. *Seed-down* ſmaller and ſhorter than in either of the former.

4. H. *cretica*. Willd. n. 4. (Hyoſeris cretica; Linn. Sp. Pl. 1139. Scop. Del. Inſub. v. 1. 36. t. 16.)—Stem branched, diffuſe. Leaves oblong, toothed, claſping the ſtem. Calyx of the fruit ſmooth; briſtly at the top. Seed-down of the radius ſomewhat compound.—Native of Crete, where Tournefort ſeems firſt to have obſerved it. The *leaves* are very deeply toothed, ſo as to become almoſt pinnatifid, and moſtly very rough. *Stem* decumbent. Flowering *branches* elongated and ſlender, nearly or quite ſmooth. Crown of the outer row of *ſeeds* much more leafy or divided, as well as longer, than in any of the above, and not that ſimple ciliated cup uſual in the genus. How far this may be conſtant we know not. The ſpecies are all very much alike, and many of the marks by which they have been, or might be ſuppoſed likely to be, diſtinguiſhed, prove fallacious. We have had no opportunity of ſtudying and comparing them alive. The following is known to us by Willdenow's account only.

5. H. *pendula*. Willd. n 5.—"Stem erect, panicled. Leaves oblong, hiſpid, deeply toothed. Calyx of the fruit ſmooth; briſtly at the top."—Native country unknown. Willdenow received a dried ſpecimen from Dr. Balbis, by the name of *Hyoſeris pendula*, which does not occur either in his Italian ſelection of plants found near Turin, nor in the catalogue of the garden there, printed in 1801. *Root* annual. *Stem* a foot and a half high, clothed, like the whole of the herb, with forked briſtles; panicled at the top. Lower *leaves* obovate, toothed and ſomewhat runcinate; the upper ones oblong, deeply toothed, claſping the ſtem. *Flower-ſtalks* ſwelling. *Flowers* pendulous before they open, as in the laſt.

HEDYSARUM, from ἡδὺς, *ſweet*, the name of a plant in Dioſcorides, which, he tells us, thoſe who make ointments call Ἡδύσαρον, or hatchet-plant, becauſe the ſeed reſembles a two-edged hatchet. This was probably ſome ſpecies of *Trigonella*, (Fenugreek,) or ſomething nearly allied thereto. He deſcribes it as "having minute leaves like thoſe of lentils, *Cicer arietinum*, and pods like little horns, in which is an orange-coloured ſeed, ſhaped as above deſcribed, with a bitter taſte;" all which, except the ſhape of the ſeed itſelf, agrees well with ſeveral *Trigonellæ*, whoſe peculiar ſcent would eaſily procure them the appellation of ἡδύσαρον. Dioſcorides attributes to his plant ſtomachic and reſtorative virtues, for which the ſeed of Fenugreek is, to this day, introduced into the curry-powders of that ancient people the Hindoos. Whatever the Greek plant might be, the name of *Hedyſarum* is now univerſally applied by botaniſts to a genus, with which its ancient hiſtory has no further agreement, than in the ſole point in which the above fails, the ſhape of the ſeed, or rather fruit, whoſe reſemblance to a two-edged hatchet is ſtill but obſcure, and con-

fined to a few ſpecies only.—Linn. Gen. 382. Schreb. 505. Willd. Sp. Pl. v. 3. 1171. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 63. Sm. Fl. Brit. 778. Juſſ. 362. Tourn. t. 225. Lamarck. Illuſtr. t. 628. Gærtn. t. 155. (Onobrychis; Tourn. t. 211. Alhagi; Tourn. t. 489.) —Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, inferior, divided half way down into five awl-ſhaped, erect, permanent ſegments. *Cor.* papilionaceous, ſtriated: ſtandard long, ovate-oblong, emarginate, the ſides bent downwards, and rather compreſſed; wings oblong, ſtraight, narrower than the other petals; keel ſtraight, compreſſed, broader towards the end, abrupt, ſo as almoſt to form a right angle, divided from the baſe to the angle, otherwiſe united into one petal. *Stam.* Filaments in two ſets, one compoſed of nine, the other ſolitary, all bent together upwards, at a right angle; anthers roundiſh, compreſſed. *Piſt.* Germen ſlender, compreſſed, linear; ſtyle awl-ſhaped, bent with the ſtamens; ſtigma perfectly ſimple. *Peric.* Legume of one or more roundiſh, compreſſed, ſingle-ſeeded joints, not burſting. *Seed* kidney-ſhaped, ſolitary.

Eſſ. Ch. Calyx five-cleft. Corolla with a tranſverſely obtuſe keel. Legume of ſingle-ſeeded cloſed joints.

This is a vaſt genus. The 14th edition of the *Syſtema Vegetabilium* contains 67 ſpecies; Willdenow has 117, though ſeveral of the Linnæan ones are removed to Swartz's *Styloſanthes*, and more to the *Hallia* of Thunberg. See HALLIA.—They are divided by their leaves into four pretty natural ſections. Firſt, ſuch as have ſimple leaves, of which there are properly but 16 of the above 117, for *H. veſpertilionis* has, when in perfection, ternate ones; ſecondly, two with conjugate leaves; thirdly, 64 with ternate leaves; and laſtly 35, whoſe foliage is pinnate.—The ſtructure of the legume, or its joints, is often very remarkable. They are ſometimes rough, ſometimes curiouſly reticulated, ribbed, or creſted, and the briſtles which border or cover ſome of them are hooked, ſo as to cling to the coats of animals. Theſe joints, whether ſolitary, as in *H. Onobrychis*, the common ſaintfoin, or attached to one another ſo as to reſemble a necklace, fall to the ground entire; nor do they let the ſeed go, till the young ſprouting plant forces its way through the decaying coats of the pericarp. In *H. criſtatum*, and ſome few others, the ribs or ſkeleton of the very curious ſeed-veſſel is often found inſeparable from the crown of the root in the full-grown plant.—Some recent botanical writers have given the name of *lomentum* to this kind of pod, which, ſtrictly ſpeaking, cannot be ſaid to conſiſt of two valves, as it does not burſt. But the diſtinction ſeems to us not very material, nor the name correct. *Lomentum* is either a kind of colour, or the meal or flour of beans uſed by the ancients, apparently in a ſort of waſh or lotion, to ſmooth the ſkin. Hence perhaps Linnæus called an order of large mealy-ſeeded plants, akin to pulſe, *lomentaceæ*; but that will not juſtify the application of this name to their ſeed-veſſels, for which we can find no authority, either in Linnæus or elſewhere. See Martyn's Language of Botany, and Milne's Botanical Dictionary, the learned authors of which, no ſervile copyiſts, have found it difficult to explain even the term *lomentaceæ*.

1. Of the ſimple-leaved ſpecies of *Hedyſarum*, the following are examples.

H. *Alhagi*. (Algul, or Agul; Rauwolf. It. 173. t. 94.) Leaves ſimple, lanceolate, obtuſe. Stem ſhrubby, ſpinous. —Native of Armenia, Georgia, Perſia, Syria, Meſopotamia, and ſome parts of Tartary; alſo of the iſlands of Syros and Tenos in the Archipelago, according to Tournefort, who has given a full account of this ſhrub, in his Voyage, v. 1. 123, and who eſtabliſhed it as a genus, diſtinct from *Hedyſarum*, on account of its ſimple alternate leaves. The *root* is woody. *Stems* about a yard high, branched from the bottom, pale, ſmooth, hard, pliable. *Leaves* not unlike thoſe of knot-graſs, (*Polygonum aviculare*,) ſeven or eight lines long, pale green and ſmooth. *Thorns* numerous, firm, ſharp, both axillary and terminal. Two or three elegant *flowers*, variegated with pink and purple, are ſituated on each of the terminal thorns. The *legume* is an inch long, curved, formed of ſeveral necklace-like joints, that eaſily ſeparate from each other when ripe. This plant produces the manna uſed in Perſia, very different from that of the flowering aſh, which is the common kind. The drug is principally collected about Tauris, and is known by the name of *Trungibin* or *Terenjabin*. The Arabian writers believed that it fell from the clouds upon this ſhrub, but it is a natural exudation from the leaves and branches, which takes place only in very hot weather. At firſt the manna reſembles drops of honey, but ſoon thickens into little ſolid grains, as big as coriander ſeeds at moſt. It is collected with more or leſs care, and is valued in proportion to its purity, which is evinced by the diſtinctneſs of the granulations. The coarſer ſort, formed into little balls like loaves, is of a reddiſh brown, full of dirt and leaves. Tournefort ſays the general doſe of either kind is from 25 to 30 drams, which, if there be no miſtake, ſhews it to be leſs active than our officinal manna, and we hope it is leſs nauſeous.

The reſt of this ſection conſiſts almoſt entirely of tropical plants, among which *H. ſtrobiliferum*, rudely figured in Linn. Fl. Zeyl. t. 3, is one of the moſt ſtriking, on account of the abundance of large pale downy bracteas, contraſted with the beech-like leaves. This fine ſhrub, a native of the Eaſt Indies, was firſt raiſed in England by A. B. Lambert, eſq., in his ſtove at Boyton, where it bloſſomed copiouſly about 1789.

2. The twin-leaved ſpecies are *H. diphyllum*, (Nélammári; Rheede Malab. v. 9. t. 82.), native of the Eaſt Indies; a ſmall herbaceous annual of no beauty; and *H. conjugatum* of Willdenow, reckoned by Linnæus a variety of the former; ſee *Burm. Zeyl. t.* 50. *f.* 1.

3. Of thoſe with ternate leaves, *H. veſpertilionis* ought to ſtand firſt; ſee Jacq. Ic. Rar. t. 566. This is a native of Cochinchina, very remarkable for its ſhallow, broad, ſingularly ſtriped, terminal leaflets, and has been often raiſed in our ſtoves. The flowers are white and inconſpicuous.

H. pulchellum, figured in Burm. Zeyl. t. 52, much reſembles *ſtrobiliferum* at firſt ſight, having long cluſters, with twin orbicular bracteas at each little tuft of bloſſoms. The Eaſt and Weſt Indies, North America, Japan, and ſome other parts of the globe, produce various ſpecies of this ſection. One of the moſt intereſting vegetables in the world ranges among them, the celebrated moving plant, *H. gyrans*, Linn. Suppl. 332. Jacq. Ic. Rar. t. 565, which is found on the ſhores of the Ganges in Bengal. This is biennial, though of a ſhrubby habit, bearing long ſpikes of pale particoloured flowers. Its great ſingularity conſiſts in the leaves, of which the central or terminal leaflet is large, elliptic-oblong, dependent, two or three inches in length, with a central glaucous ſtripe. The lateral leaflets are very ſmall, obovate, narrow, ſtanding a little below the former upon the common footſtalk. Theſe have a peculiar and ſpontaneous motion, both moving together from a pendent to an erect poſture, or the reverſe, with tolerable rapidity; or one of them will move, regularly by ſtarts, while the other is ſtationary. This motion does not take place in all the leaves of one plant or branch at a time, but is quite devoid of all uniformity, regularity, ſympathy, or conſent. It is likewiſe

likewiſe independent of all external ſtimulation, except that it requires a warm, cloſe, and quiet atmoſphere, being impeded by wind, or by a current of cool air, though the abſence or preſence of light is equally indifferent as to its performance. Young plants exhibit this phenomenon beſt. We have never ſeen it in ſo much perfection as by candle-light in a very warm cloſe apartment. The younger Linnæus in his full and animated account of this wonderful plant, to which nothing parallel is known, juſtly obſerves that "it loves ſhade, and rainy weather, and performs its movements very well during the whole night."

4. The laſt ſection comprehends ſome beautiful ſpecies; as *H. pictum*, Jacq. Ic. Rar. t. 567, a ſplendid native of Guinea. Each leaf has about four pair, with an odd one, of linear leaflets, ſix inches or more in length, narrow, moſt beautifully painted with a ſinuous, white, longitudinal ſtripe. The ſpikes are terminal, above a foot long, conſiſting of innumerable pale purple flowers, with a pair of white ſpots at the baſe of the ſtandard.

The Siberian *H. argenteum*, meanly delineated in Gmel. Sib. v. 4. t. 13, is a very ſhowy herbaceous plant, on account of its ſilvery leaves, and large white ſattiny flowers.

H. *alpinum*, and *obſcurum*, Curt. Mag. t. 282, are two handſome alpine ſpecies, with crimſon flowers. To theſe is akin *H. coronarium*, common in gardens by the name of French Honeyſuckle; and *H. roſeum*, Sims in Curt. Mag. t. 996, raiſed by the excellent Mr. Loddiges from ſeed obtained from Mount Caucaſus.

The only Britiſh ſpecies of *Hedyſarum* is one of thoſe, belonging to this ſection, which have the legume ſimple, or conſiſting of a ſolitary joint; *H. Onobrychis*, or ſainfoin. Jacq. Auſtr. t. 352. Engl. Bot. t. 96. A native of chalky hillocks and downs, in various parts of England, flowering in June and July, when it greatly adorns thoſe arid open ſpots, which it prefers to a more rank or moiſt ſoil. The name *Onobrychis* expreſſes its being a favourite food of aſſes. It is no leſs acceptable to their more noble congener the horſe, and to horned cattle, being now very commonly cultivated for fodder in places favourable to its growth, which fortunately are ſuch as do not ſo well ſuit corn or graſs. Profeſſor Martyn has proved that ſainfoin was firſt known amongſt us about the middle of the 17th century, and that the ſeed, with the name, came from France and Flanders.

HEE Grass, in *Rural Economy*, a name in ſome caſes provincially employed to ſignify the ſtumps or ſharp ſtubs of ſuch graſs as has been mown.

HEEDER, a term provincially employed in ſome caſes to ſignify a male ſheep; the female being denominated a *Sheeder*. See Sheeder.

HEEL, in *Anatomy*, the hind part of a foot.

In winter, the heels are liable to a kind of chilblains called *kibes*, which ſometimes tend to a mortification.

The bone of the heel is called *calcaneum*.

Heel *of a horſe*, is the loweſt hind part of the foot, comprehended between the quarters and oppoſite to the toe.

The heel ſhould be high and large, and one ſide not riſe higher on the paſtern than the other. The diſtempers incident to this part are ſcabbineſs and ſcratches.

Some narrow-heeled horſes have high heels, but ſo weak and tender, that by preſſing the two ſides of the heel one againſt another they will ſenſibly yield. See Hoof.

Heels, *to open the*, is to pare the foot and cut the heel low, almoſt cloſe to the fruſh; taking it down within a finger's breadth of the coronet or top of the hoof, ſo as to ſeparate the quarters, and by that means weaken and take away the ſubſtance of the foot, and make it cloſe and become narrow at the heels.

Heel *of a horſeman*. This being the part which is armed with a ſpur, the word is uſed for the ſpur itſelf; as, this horſe underſtands the heels well.

To ride a horſe from one Heel *to another*, is to make him go ſideways, ſometimes towards one heel, and ſometimes another.

Heel, in *Architecture*, a moulding, the ſame as the cima-reverſa. See Cymatium.

Heel *of a rafter*, the foot of the rafter, is cut to coincide with the top of the wall plate, when the rafter is put into its poſition in the inclined ſide of the roof.

Heel, in *Sea Language*, is a name often given to the after-end of a ſhip's keel; and alſo to the lower-end of the ſtern-poſt to which it is firmly jointed.

If a ſhip lean on one ſide, whether aground or afloat, they ſay ſhe heels a-ſtarboard or afloat, or ſhe heels offward or to the ſhore; that is, ſhe inclines more to one ſide than to the other.

Heel *of a maſt*, is that part of the foot thereof which is pared away ſlanting, that the maſt may be ſtayed afterward on it.

Heel *of a top maſt*, is the lower end, ſuſtained on the treſſel-trees by means of an iron bar, called the *fidd*.

HEELER, or *Bloody Heel Cock*, is a fighting cock which ſtrikes or wounds much with his ſpurs.

The maſters know ſuch a cock, even while a chicken, by the ſtriking his two heels together in his going.

HEEM, John David de, in *Biography*, an excellent painter of flowers and other articles of ſtill life, who was born at Utrecht in 1600. His father, David de Heem, firſt inſtructed him in the art, and guided his taſte in the objects of his purſuit; and he had the pleaſure of ſeeing his ſon riſe to a degree of eminence, far ſurpaſſing that which he was himſelf able to obtain.

John de Heem painted, with very great ſucceſs, compoſitions of conſiderable difficulty; made up of carpets, vaſes, fruits, flowers, &c.; which he wrought in a free rich ſtyle, with a flowing pencil, and full colour; with great correctneſs of imitation; not minute, but free characteriſtic exactneſs. His colouring is exceedingly tranſparent and brilliant, and his works were deemed ſo meritorious, that in his life time they were ſold at very conſiderable prices; and of courſe fell only into the hands of men of large fortunes; they are therefore very ſcarce to be met with. He died in 1674, at the age of 74, leaving a ſon, *Cornelius de Heem*, whom he inſtructed in the ſame line of art as he himſelf practiſed; but who never aroſe to the ſame degree of excellence with his father, though he was a very good painter, and his works are ſometimes ſold as of his father's production.

HEEMSKERK, James Van, a celebrated naval commander, was a native of Amſterdam, and devoted from his youth to the ſea. In 1596, he ſailed with others, in order to diſcover a north-weſt paſſage to China, but the hardſhips they had to endure were ſuch as to oblige them to abandon their enterpriſe. Heemſkerk was afterwards employed in the navy of Holland; he was ſent, in 1607, as vice-admiral, with twenty-ſix ſhips of war, to cruiſe againſt the Spaniards, an engagement enſued, in which Heemſkerk had his leg carried off, an accident which, in a few minutes, put an end to his life, but he died exhorting his men to perform their duty. Their efforts were crowned with ſucceſs, the Spaniſh admiral was killed, his ſon made priſoner, and many of their ſhips burnt or ſunk. The body of Heemſkerk was brought home, buried at Amſterdam

at

at the public expence, and a monument was erected to his memory. Moreri.

HEERAPOUR, in *Geography*, a town of Hindooſtan, in Gurry Mundella; 14 miles S.S.W. of *Mundella*.—Alſo, a town of Hindooſtan, in Malwa; 40 miles E. of Chatterpour.—Alſo, a town of Hindooſtan, in Guzerat; 30 miles N. E. of Surat.

HEERE, Lucas de, in *Biography*, a painter of very conſiderable reputation in his time; which, however, was not that of the beſt period of the art. He was born at Ghent in 1584. His father was the beſt ſtatuary of his time, and his mother, whoſe maiden name was Anne Smythers, had the reputation of an extraordinary paintreſs; ſo that Lucas ſet forth with conſiderable advantages. Having, under the inſtruction of his parents, learned the firſt principles of deſign, and to handle the pencil with eaſe and freedom, he was placed as a diſciple with Francis Floris, under whoſe tuition he made conſiderable progreſs, and Pilkington ſays, he became in ſome reſpects equal to his maſter, and in compoſition and invention his ſuperior; but this appears to be inflated encomium, and ariſes from De Heere being afterwards more employed by exalted perſons than Floris was.

When he quitted Floris he went to France, where the queen's mother employed him for ſome years in drawing deſigns for tapeſtry. It is ſaid, that while he was at Fontainbleau, he ſtudied much from the antique ſtatues; but whatever his ſtudies of that kind were, he might as well have ſaved the time he beſtowed upon them, as he never was able to adopt, or apply any of thoſe principles on which they are wrought to his ſubſequent works, which are in general tame and laboured imitations of nature as he found her; and not very correct either, being dry and ſomewhat Gothic in their ſtyle.

At his return to Ghent he painted ſeveral portraits very ſucceſsfully; and is ſaid to have had ſo tenacious a memory with regard to forms, that if he ſaw a perſon once, he would paint his likeneſs as ſtrong as if he had the model before his eyes. He alſo was employed at Ghent on ſeveral altar pieces. In the church of St. Peter's, he painted the Lord's Supper. In St. John's, the Reſurrection of Chriſt; and on the doors which covered the picture, Chriſt and the two diſciples of Emmaus.

De Heere came to England about 1557 or 8, and had the honour of painting queen Elizabeth; which picture is now in the royal collection at Kenſington palace. According to Walpole, the queen is repreſented in a rich dreſs with the emblems of royalty; and the goddeſſes Juno, Pallas, and Minerva, ſeem flying from before her. Juno drops her ſceptre, Venus her roſes, Cupid, alſo preſent, flings away his uſeleſs bow and arrows and clings to his mother; and on the old frame are ſome Latin verſes explanatory of this idle flattery; probably of the painter's own compoſing, who dabbled in both the ſiſter arts of painting and poeſy. Beſides this, he painted a great many portraits here, which are to be ſeen in the houſes of the nobility, and ſeveral of which Vertue has engraved. Lady Jane Grey, lord Darnley, huſband of Mary queen of Scotland, Frances, ducheſs of Suffolk, &c. and at Longleate, there is a large picture of a gentleman, his wife and family, conſiſting of eight other perſons. Soon after he came to England, he painted a naked man with different coloured clothes lying beſides him, and a pair of flowers in his hand, as a ſatire on our fickleneſs in faſhion; it is illuſtrative of a verſe by Andrew de Borde, who in his Introduction to Knowledge, has prefixed to the firſt chapter a naked man with theſe lines:

"I am an Engliſhman, and naked I ſtand here,
Muſing in mind what raiment I ſhall wear."

De Heere, before he died, which happened in 1584, in the 50th year of his age, returned to Ghent; but his laſt works are unknown. It was his cuſtom always to mark his pictures with the dates of their production; and with his own initials combined in one form.

HEERENBERG, in *Geography*, a town of Holland, in the county of Zutphen; 15 miles S. E. of Arnheim.

HEERENVEN, a town of Holland, in the ſtate of Frieſland, called, on account of its extent and neatneſs, the "Hague of Frieſland;" 15 miles S.S E. of Leewarden.

HEERINGEN, a town of Germany, in the county of Schwartzburg Rudolſtadt, on the Helm; ſix miles S.E. of Nordhauſen. N. lat. 51° 27'. E. long 10° 59'.

HEERLEN, a town of France, in the department of the Lower Meuſe; and chief place of a canton, in the diſtrict of Maeſtricht. The place contains 3218, and the canton 7231 inhabitants, on a territory of 90 kiliometres, in five communes.

HEERMUND. See Hindmend.

HEERS, Henry de, in *Biography*, a phyſician, was of a noble family of Tongers, an ancient town in the biſhopric of Liege, where it is believed he was born about the year 1570. He diſtinguiſhed himſelf while young, by his attainments in philoſophy and the mathematics; and ſpending ſome time in each of the countries of Europe, through which he travelled, namely, Germany, Italy, Spain, France, and England, he learnt their reſpective languages, to which he added a knowledge of the Latin, Greek, and Hebrew tongues. In the courſe of his travels he took the degree of M. D., and finally ſettled in the practice of his profeſſion at Liege, about the year 1605. He was phyſician to the princes Erneſt and Ferdinand of Bavaria during upwards of thirty years; and is ſaid to have died about the year 1636. De Heers, or Ab Heers, as he calls himſelf in his Latin works, was a man of no leſs acuteneſs of penetration and ſolidity of judgment, than of profound and extenſive erudition; and he perſiſted in ardent ſtudy to the end of his life. He left the following works; "Spadacrene, hoc eſt, Fons Spadanus, ejus ſingularia, bibendi modus, medicamina bibentibus neceſſaria," Leodij, 1614. This work underwent ten or more ſubſequent editions.—"Deplementum ſupplementi de Spadanis fontibus, ſive, Vindiciæ pro ſua Spadacrene," Leodij, 1624. This was an anſwer to John Baptiſt Van Helmont, whom he treats rather ſeverely.—"Obſervationes Medicæ oppido raræ in Spa et Leodij animadverſæ, cum aliquot medicamentis ſelectis," Leodij, 1631;—republiſhed at Leipſic, in 1635; and at Lyons in 1685. The author paſſed a few weeks annually at Spa. Eloy. Dict. Hiſt.

HEES, in *Geography*, a town of Holland; 17 miles S S.E. of Bois le Duc.

HEGAD, one of the Sooloo iſlands. N. lat. 6° 7'. E. long. 121°.

HEGAW, or Hegow, a part of Germany, in the circle of Swabia, which borders on the Boden ſee, or lake of Conſtance.

HEGEMONE, in *Mythology*, one of the *Graces*; which ſee.

HEGESIPPUS, in *Biography*, who flouriſhed in the ſecond century, was by birth a Jew, and educated in the religion of his fathers. He afterwards was converted to the Chriſtian faith, became a biſhop at Rome about the year 177, where he died in the reign of the emperor Commodus, about the year 180. He was author of an eccleſiaſtical hiſtory

hiſtory from the death of Chriſt to the time in which he lived, which, according to Euſebius, contained a faithful relation of the apoſtolic preaching, written in a very ſimple ſtyle. The principal value of the exiſting fragments ariſes from the teſtimony which may be deduced, from ſcriptural paſſages quoted in them, in favour of the genuineneſs of the books of the New Teſtament. Moreri. Lardner.

HEGIRA, in *Chronology*, a celebrated epocha, uſed by the Arabs and Mahometans for the computation of time.

The word is Arabic, formed of הגרת, *hagirath*, *flight*, or *departure*, of הגר, *to fly*, *to quit one's country*, *family*, *friends*, &c. It is written after the Arabic word *Hejerà*, the Arabic letters of which it is compoſed being *H*, *j*, *r*, *à*, or *ah*, and the ſupplied vowels are to be pronounced ſhort.

The event which gave occaſion to this epocha, was Mahomet's flight from Mecca to Medina. The magiſtrates of that city, fearing his impoſtures might raiſe a ſedition, reſolved to expel him: this, they accordingly effected in the year of our Lord 622, and of the Julian period 5335, on the evening of the 15th or 16th of July.

To render this epocha more creditable, the Mahometans affect to uſe the word hegira in a peculiar ſenſe, for an act of religion, whereby a man forſakes his country, and gives way to the violence of perſecutors and enemies of the faith; they add, that the Koreſhites, or Koreiſh, being then the ſtrongeſt party in the city, obliged their prophet to fly, having previouſly conſpired to kill him; as not being able to endure his aboliſhing of idolatry. Their conſpiracy, as it is pretended by Mahomet himſelf, was revealed to him by the angel Gabriel, who had now ordered him to retire to Medina. This flight was not the firſt of Mahomet's, but it was the moſt famous. It happened in the thirteenth year from his aſſuming the character of prophet and apoſtle, and promulgating his new religion.

The Orientals do not agree with us as to the time of the hegira. Among the Mahometans, Amaſi fixes it to the year of Chriſt 630, and from the death of Moſes 2347; and Ben Caſſem, to the year of the world 5800; according to the Greek computation, among the Chriſtians, Said Ebn Batrik refers the hegira to the year of Chriſt 614, and of the creation 6114. But there is another hegira, and the earlier too, though of leſs eminence. Theſe two hegiras the Mahometans, in their language, call *hegiratan*.

This event, which took place at the time and in the manner above ſtated, though little memorable in itſelf, and deriving no celebrity from the circumſtances attending it, was, 18 years after, diſtinguiſhed by Omar, the ſecond caliph, as the criſis of their new religion, and eſtabliſhed as an epoch, to which the dates of all the tranſactions of the faithful ſhould have reference in future time. This eſtabliſhment was made in imitation of the Chriſtians, who, in thoſe times, reckoned their years from the perſecution of Dioclefian. Previouſly to this, the people had been accuſtomed to compute from the commencement of a particular war, the day of a remarkable battle, or other occaſional event of importance to their little communities. In order to remedy this confuſion, the caliph enjoined the obſervance of a determinate era, in which the ſtrongeſt prejudices of the people ſhould be made to concur with the ſovereign authority. The date of the hegira was thenceforth expreſſed in all the public acts and letters. Omar did not think it expedient to attempt at any innovation as to the time of beginning the year, againſt which the ideas of the people would have revolted; and, therefore, although the eſcape of Mahomet from the indignation of his fellow-citizens was effected, according to their records, on the firſt day of the third month, or rabee prior, (on the 12th day of which he reached Medina,) yet the hegira takes its date from a period two months antecedent to this flight, *viz.* from the firſt day of Moharram, being the day on which immemorial cuſtom had eſtabliſhed the celebration of the feſtival of the new year. The Arabian and Syrian Chriſtians, and the Mahometan aſtronomers in general, appear to have fixed this day on Thurſday, the 15th of the Syro-Macedonian month Tamooz, anſwering to our July; but ſome among the latter, and moſt of their hiſtorical writers, refer it to the next day, Friday the 16th, and this latter date has, in modern times, obtained almoſt univerſal acceptance. A religious preference, which Friday claims above the reſt of the week, ſeems to have given effect to the arguments in its favour. The difference of opinion on this ſubject has ariſen, in the firſt place, from the uncertainty unavoidably attending a date, to be aſcertained at a diſtant period of time, from the phaſe of the moon, which is retarded or advanced by ſo complicated a variety of circumſtances; and the ambiguity appears, in the ſecond place, to have been promoted by the cuſtom of the Arabs, beginning their day at ſun-ſet; comformably with which idea, the time when the moon became viſible at Mecca, being the evening of Thurſday the 15th, according to our mode of computation, was to them the commencement of Friday, which Friday (beginning a few hours later) we term the 16th of July. At that period the cycle of the ſun was 15; the cycle of the moon, or golden number, 15; the Roman indiction, 10; and the dominical letter, C. For the mode of computing the beginning and duration of the year, we refer to the article *Arabic*, &c. Year.

In the year of Chriſt 622, the hegira commenced on the 16th of July, with the Arabian month Moharram; and conſidered as an ordinary, or ſimple year, it conſiſted of 354 days, but as a year of exceſs, an intercalary day is added to the laſt month Dulhajee, and it contains 355 days. The year of the Mahometans, indeed, conſiſts of twelve lunar months, each containing 29 days, 12 hours, and 792 ſcruples, or parts in 1080 (1080 ſcruples making an hour); ſo that the year contains 354 days, 8 hours, and 864 ſcruples. In order to reduce this year to an integral number of days, a cycle of 30 was choſen as the moſt convenient period, becauſe 30 times 8 hours and 864 ſcruples amount exactly to 11 days; and in this cycle there are 19 years of 354 days, and 11 of 355; the intercalary day is added at the end of the 2d, 5th, 7th, 10th, 13th, 16th, 18th, 21ſt, 24th, 26th, and 29th years of the cycle. The commencement of each year of the hegira will never fall on the ſame day of the month, according to our calendar, but will anticipate about 11 days. In order to reduce theſe years to the Julian calendar, *i. e.* to find what Julian year a given year of the hegira correſponds to, reduce the given year of the hegira into days, by multiplying by 354, divide the product by 365, and to the quotient add 622. *E. G.* To find the Julian year correſponding to 1225 of the hegira; $\frac{1225 \times 354}{365} + 622$ = 1810. Mr. Marſden (Phil. Tranſ. vol. lxxviii. part 2.) has given a very valuable table, exhibiting the correſpondence of the years of the hegira with thoſe of the Chriſtian era, and the month and day of their reſpective commencement; in which he has improved upon thoſe of Greaves in his "Epochæ Celebriores," Ulug Beighi, publiſhed in 1650, and thoſe in the "Chronologia Reformata" of Riccioli, 1659, and the "Ephemerides," Mat. Fred. Beckii, 1695. The firſt year of the hegira began, as we have already mentioned, A. D. 622, July 16th. The 1201ſt of the hegira, which is the 1ſt of the cycle, began A. D. 1786, Oct. 24, ſo that the table may be eaſily formed, or extended to any length,

length, either backward or forward. Until the beginning of the laſt century, this table diſtinguiſhes only every 10th year; but the intervals may be calculated with eaſe and preciſion by means of the obſervations that relate to the cycle; or by deducting 11 days from every year which has elapſed ſince the commencement of the cycle. Thus, the 2d year of the hegira commences 623, July the 5th; the 32d year commenced 652, Auguſt 13th, &c. The table is here ſubjoined.

Table exhibiting the Correſpondence of the Years of the Hegira with thoſe of the Chriſtian Era.

HEIDEGGER, JOHN JAMES, in *Biography*, a ſucceſsful adventurer, who arrived in England the beginning of the laſt century, and who, by his addreſs and talents, became, with the gay and faſhionable, an important perſonage in every day's converſation, and news-paper. He was the ſon of a clergyman, and a native of Zurich in Switzerland, where he married, but left his country in conſequence of an intrigue. (Anecdotes of Hogarth by Nichols.) Having had an opportunity of viſiting the principal cities of Europe, he acquired a taſte for elegant and refined pleaſures, which united to a ſtrong inclination for voluptuouſneſs, by degrees qualified him for the management of public amuſements. In 1708, when he was near 50 years old, he came to England on a negotiation from the Swiſs at Zurich; but failing in his embaſſy, he entered as a private ſoldier in the guards for protection. By his ſprightly, engaging converſation, and inſinuating addreſs, he ſoon acquired the good graces of our young people of faſhion; from whom he obtained the appellation of "the Swiſs Count." He is twice mentioned under this title in the "Tatler," Nos. 12. and 18; and in Mr. Duncomb's "Collection of Letters of ſeveral eminent Perſons deceaſed," there is a humorous dedication of Mr. Hughes's "Viſion of Chaucer" to "the Swiſs Count." He had the addreſs to procure a ſubſcription, with which, in 1709, he was enabled to furniſh out the opera of "Thomyris," which was written in Engliſh, and performed at the queen's theatre in the Haymarket. The muſic, however, was Italian, conſiſting of airs ſelected from the operas of Bononcini, Scarlattti, Steffani, Gaſparini, and Albinoni. Moſt of the ſongs in "Thomyris" were excellent for the time, particularly thoſe by Bononcini.

Valentini, Margarita, and Mrs. Tofts ſung in it; and Heidegger, by this performance alone, was a gainer of 500 guineas.

He is ſaid, by Motteux, to have ſelected the airs for Thomyris; he appears as a dramatic writer in the dedication to Antiochus; and likewiſe in that of the opera of "Amadige," or Amadis of Gaul, which he dedicates to the earl of Burlington in 1715, and which he ſays, "more immediately claimed his lordſhip's protection, as it was compoſed in his own family, meaning by Handel, who reſided in Burlington houſe, as his lordſhip's maeſtro di cappella.

The judicious remarks which he made on ſeveral defects in the conduct of our operas in general, and the hints which he threw out for improving the entertainments of the royal theatre, ſoon eſtabliſhed his character as a good critic. Appeals were made to his judgment; and ſome very magnificent and elegant decorations, which were introduced upon the ſtage in conſequence of his advice, gave ſuch ſatisfaction to George II., who was fond of operas, that upon being informed to whoſe genius he was indebted for theſe improvements, his majeſty was pleaſed from that time to countenance him, and he ſoon obtained the chief management of the opera-houſe in the Haymarket. He then ſet about improving another ſpecies of diverſion, not leſs agreeable to the king, which was maſquerades, and over theſe he always preſided at the king's theatre. He was likewiſe appointed maſter of the revels. The nobility now careſſed him ſo much, and had ſuch an opinion of his taſte, that all ſplendid and elegant entertainments given by them upon particular occaſions, and all private aſſemblies by ſubſcription, were ſubmitted to his direction.

From the emoluments of theſe ſeveral employments, he gained a regular and conſiderable income, amounting, it is ſaid, in ſome years, to 5000*l.*, which he ſpent with much liberality; particularly in the maintenance of perhaps a ſomewhat too luxurious table; ſo that it be may ſaid, that he raiſed an income, but never a fortune.

His peccadillos, however, if they may be called by ſo mild a name, were completely "covered" by his "charity."

After a ſucceſsful maſquerade, he has been known to give away ſeveral hundred pounds at a time. "You know poor objects of diſtreſs better than I do," he would frequently ſay to the father of the gentleman who furniſhes this anecdote: "be ſo kind as to give away this money for me." This well-known liberality, perhaps, contributed much to his carrying on that diverſion with ſo little oppoſition as he experienced.

Pope (Dunciad, 1. 289) calls the bird which attended on the goddeſs—"a monſter of a fowl," ſomething betwixt a Heidegger and "owl," and explains Heidegger to mean "a ſtrange bird from Switzerland, and not (as ſome have ſuppoſed) the name of an eminent perſon, who was a man of parts, and as was ſaid of Petronius, "arbiter elegantiarum."

That he was a good judge of muſic appears by the airs which he ſelected for ſeveral of the firſt paſticcio operas: but this is all that is known of his mental abilities: unleſs we add, what we have good authority for ſaying in honour to his memory, that he walked from Charing-croſs to Temple-bar, and back again; and when he came home wrote down every ſign on each ſide of the Strand.

As to his perſon, though he was tall and well made, it was not very pleaſing, from an unuſual hardneſs of features.

There is a mezzotinto of Heidegger by J. Faber 1742, (another copy dated 1749) from a painting by Vanloo, a ſtriking likeneſs, now (1784) in the poſſeſſion of Peter Crawford, eſq. His face is alſo introduced in more than one of Hogarth's prints.

But he was the firſt to laugh at his own uglineſs; and he once laid a wager with the earl of Cheſterfield, that, within a given time, his lordſhip would not be able to produce ſo hideous a face in all London. After ſtrict ſearch, a woman was found, whoſe features were at firſt ſight thought ſtronger than Heidegger's; but upon ſetting her head-dreſs upon himſelf, he was univerſally allowed to have won the wager. Jolly, a well-known taylor, carrying his bill to a noble duke; his grace, for evaſion, ſaid, "Dam your ugly face, I will never pay you till you bring me an uglier fellow than yourſelf!" Jolly bowed and retired, wrote a letter, and ſent it by a ſervant to Heidegger; ſaying his grace wiſhed to ſee him the next morning on particular buſineſs." Heidegger attended, and Jolly was there to meet him; and in conſequence, as ſoon as Heidegger's viſit was over, Jolly received the caſh.

The late facetious duke of Montague (the memorable author of the bottle conjuror at the theatre in the Haymarket) gave an entertainment at the Devil-tavern, Temple-bar, to ſeveral of the nobility and gentry, ſelecting the moſt convivial, and a few hard-drinkers, who were all in the plot. Heidegger was invited, and in a few hours after dinner, was made ſo dead drunk that he was carried out of the room, and laid inſenſible upon a bed. A profound ſleep enſued; when the late Mr. Salmon's daughter was introduced, who took a mould from his face in plaiſter of Paris. From this a maſk was made, and a few days before the next maſquerade (at which the king promiſed to be preſent, with the counteſs of Yarmouth) the duke made application to Heidegger's valet de chambre, to know what ſuit of cloaths he was likely to wear; and then procuring a ſimilar dreſs, and a perſon of the ſame ſtature, he gave him his inſtructions.

On

On the evening of the maſquerade, as ſoon as his majeſty was ſeated (who was always known by the conductor of the entertainment, and the officers of the court, though concealed by his dreſs from the company), Heidegger as uſual ordered the muſic to play "God ſave the King;" but his back was no ſooner turned, than the falſe Heidegger ordered them to ſtrike up "Over the Water to Charley." The whole company were inſtantly thunderſtruck, and all the courtiers, not in the plot, were thrown into a ſtupid conſternation. Heidegger flew to the muſic-gallery, ſwore, ſtamped, and raved; accuſed the muſicians of drunkenneſs, or of being ſet on by ſome ſecret enemy to ruin him. The king and the counteſs laughed ſo immoderately, that they hazarded a diſcovery. While Heidegger ſtaid in the gallery "God ſave the King" was the tune; but when, after ſetting matters to rights, he retired to one of the dancing-rooms, to obſerve if decorum was kept by the company, the counterfeit ſtepping forward, and placing himſelf upon the floor of the theatre, juſt in front of the muſic-gallery, called out in a moſt audible voice, imitating Heidegger, damned them for blockheads, had he not juſt told them to play "Over the Water to Charley?" A pauſe enſued; the muſicians who knew his character, in their turn, thought him either drunk or mad; but as he continued his vociferation, "Charley" was played again. At this repetition of the ſuppoſed affront, ſome of the officers of the guards, who always attended upon theſe occaſions, were for aſcending the gallery, and kicking the muſicians out; but the late duke of Cumberland, who could hardly contain himſelf, interpoſed. The company were thrown into great confuſion. "Shame! Shame!" reſounded from all parts; and Heidegger once more flew in a violent rage to that part of the theatre facing the gallery. Here the duke of Montagu, artfully addreſſing himſelf to him, told him, "the king was in a violent paſſion; that his beſt way was to go inſtantly and make an apology, for certainly the muſicians were mad, and afterwards to diſcharge them." Almoſt at the ſame inſtant he ordered the falſe Heidegger to do the ſame. The ſcene now became truly comic in the circle before the king. Heidegger had no ſooner made an humble apology for the inſolence of his muſicians, but the falſe Heidegger advanced, and in a plaintive tone, cried out; indeed, ſire, it was not my fault, "but that devil in my likeneſs." Poor Heidegger turned round, ſtared, ſtaggered, grew pale, and could not utter a word. The duke then humanely whiſpered in his ear the ſum of his plot, and the counterfeit was ordered to take off his maſk. Here ended the frolic; but Heidegger ſwore he would never attend any public amuſement, if that witch the wax-work woman did not break the mould, and melt down the maſk before his face.

To this occurrence the following imperfect ſtanzas, tranſcribed from the hand-writing of Pope, are ſuppoſed to relate. They were found on the back of a page containing ſome part of his tranſlation, either of the "Iliad" or "Odyſſey," in the Britiſh Muſeum.

Then he went to the ſide-board, and called for much liquor,
And glaſs after glaſs he drank quicker and quicker;
So that Heidegger quoth,
Nay, faith on his oath,
Of two hogſheads of Burgundy, Satan drank both.
Then Heidegger all like the Devil appear'd,
And ſtraight the whole table of diſhes he clear'd:
Then a friar, then a nun,
And then he put on
A face all the company took for his own.
Even thine, O falſe Heidegger! who wert ſo wicked
To let in the Devil——

Being once at a ſupper with a large company, when a queſtion was debated, which nationaliſt of Europe had the greateſt ingenuity; to the ſurpriſe of all preſent, he claimed that character for the Swiſs, and appealed to himſelf for the truth of it. "I was born a Swiſs," ſaid he, "and came to England without a farthing, where I have found means to gain 5000*l.* a year, and to ſpend it. Now I defy the moſt able Engliſhman to go to Switzerland, and either to gain that income or to ſpend it there."

He always ſeemed ſenſible of Handel's worth and ſuperior abilities, favouring and accommodating him in all his undertakings with the uſe of his theatre, in preference to his opponents and enemies.

He died Sept. 4th, 1750, at the advanced age of 90 years, at his houſe at Richmond, in Surrey, where he was buried.

HEIDELBERG, in *Geography*, a city of Germany, in the circle of the Lower Rhine, formerly capital of the palatinate, but ceded, in 1803, among the indemnities, to the elector of Baden. It is ſituated on the S. ſide of the Neckar, and was ſurrounded with walls in the 12th century. It has often been burnt and plundered; in 1799 it was taken by the French. The univerſity of Heidelberg was founded in 1386, and has been under the direction of 20 profeſſors, of whom four are Calviniſts. When this city was taken by the Bavarians in 1622, its library was transferred to the Vatican. Although it is now ſmall, it contains three churches for Roman Catholics and Proteſtants of different perſuaſions, ſeveral convents, an anatomical theatre, a military hoſpital, more than 20 fountains, and ſix gates. It has been noted for its wines, and for its capacious tun; it is commercial, and has manufactures of ſtuffs, ſilk ſtockings, &c. Its inhabitants are chiefly Lutherans, with a free toleration; 42 miles S. of Frankfort on the Maine. N. lat. 49° 24′. E. long. 8° 43′.

HEIDELBURG, a handſome town of America, in Dauphine county, Pennſylvania, containing about 100 houſes, and two German churches for Lutherans and Calviniſts, and 1990 inhabitants; 74 miles N.W. by W of Philadelphia.—Alſo, two townſhips in the ſame ſtate, one in York county, the other in that of Northampton, containing 1238 inhabitants.—Alſo, a Moravian ſettlement in Pennſylvania, begun in 1743; ſeven miles from Litiz, in Warwick townſhip, Lancaſter county.

HEIDELSHEIM, a town of Germany, in the palatinate of the Rhine, ſituated on the Salzbach; 17 miles S. of Heidelberg.

HEIFF, El, an iſland in the river Nile, near the great Cataract, anciently called "Pylæ;" on which are ſome remains of a temple of Iſis, and other antiquities.

HEIGHT, the third dimenſion of a body, conſidered with regard to its elevation above the ground.

To find the height of a hill, ſee the article of Leveling, towards the end.

Height, in *Aſtronomy*, *Geography*, &c. See Altitude and Elevation.

Height, in the *Manege*, &c. the ſtature of a horſe, &c.

It is reputed an imperfection in a horſe, when ſet too high on his legs, *i. e.* when the legs are too long in proportion to the body.

Some jockeys have determined a meaſure for them thus: take a ſtring, and meaſure from the horſe's withers to his elbow; and what length that is, the ſame ſhould he have betwixt the elbow and the lower part of the heels. Some meaſure their colts after this manner at a year old, being of opinion that the legs of a colt at this age are as long as they ever will be.

The duke of Newcaſtle, and ſir W. Hope, allow this to hold generally, but not univerſally.

HEIGHT *of Land*, in *Geography*, a range of mountains, extending from S.W. to N.E. and ſeparating the diſtrict of Maine from Lower Canada, giving riſe to many rivers which fall into St. Lawrence river and into the Atlantic, and between which and St. Francis river are produced beech, maple, birch, hemlock, and fir, ſome few white pines, but no oak.

HEIGHTS, in the *Military Art*, are the eminences round a fortified place, whereon the armies uſually poſt themſelves. The enemy had ſeized all the heights, appeared on the heights, &c.

HEILA, in *Geography*, a town of Pruſſian Pomerelia, at the mouth of the Viſtula, on a headland which projects into the Baltic; 24 miles N.N.E. of Dantzic. N. lat. 54° 47'. E. long. 18° 6'.

HEILBRONN, a town of Germany, on the Neckar, in a country celebrated for its vineyards. This town is well built, and contains three churches, two convents, a ſeminary, a library, and public baths. It was formerly an imperial town, but in 1802 granted as an indemnity to the duke (now king) of Wirtemberg; 26 miles S.E. of Heidelberg. N. lat. 49° 8'. E. long. 9° 18'.

HEILIGENHEIL, a town of Pruſſia, in the province of Natangen, on a ſmall river, which, ſoon after paſſing this town, runs into the Friſche Haff. It was anciently a ſeat of idolatry, in which the Pruſſians worſhipped their deity, Curetro, under a large oak. Of late it has been famous for fine beer and white bread. N. lat. 54° 26'. E. long. 19° 53'.

HEILIGENSTADT, a town of Germany, and capital of Eichsfeld, 42 miles N.W. of Erfurt. N. lat. 51° 23'. E. long. 10° 28'.—Alſo, a town in the biſhopric of Bamberg; 10 miles E. of Bamberg.

HEILIGENTHAL, a town of Pruſſia, in the province of Ermeland; 20 miles W.S.W. of Heilſberg.

HEILIGINHAFEN, a ſea-port town of the duchy of Holſtein, near the Baltic, oppoſite to the iſland of Femern: the harbour is at ſome diſtance, E. of the town. N. lat. 54° 27'. E. long. 10° 48'.

HEILSBERG, or HEILSPERG, a town of Pruſſia, in the province of Ermeland, where Charles XII. of Sweden fixed his head-quarters in 1703; 36 miles S. of Konigſberg. N. lat. 54° 3'. E. long. 20° 35'.

HEILSBRONN, a town of Germany, in the principality of Anſpach, on the Schwabach, where is a medicinal ſpring; eight miles E.N.E. of Anſpach. N. lat. 49° 20.' E. long. 10° 47'.

HEILTZ-LE-MAURUPT, a town of France, in the department of the Marne, and chief place of a canton, in the diſtrict of Vitry-ſur-Marne; 18 miles S.E. of Chalons-ſur-Marne. The place contains 940, and the canton 10,852 inhabitants, on a territory of 280 kiliometres, in 25 communes.

HEIN, PETER, in *Biography*, a celebrated Dutch admiral, born, towards the cloſe of the 16th century, of parents of obſcure rank, was, in 1623, a vice-admiral in the Eaſt Indies, and three years afterwards he had the chief command of the fleet, with which he defeated the Spaniards off the coaſt of Brazil, and took ſeveral veſſels with a rich booty. In 1628 he was appointed to the command of a fleet of 31 ſhips, fitted out by the Dutch Eaſt India company for the purpoſe of intercepting the Spaniſh Plate fleet. The project ſucceeded, and the Dutch admiral captured the whole of the ſhips, which proved to be of immenſe value. In the following year he engaged with a fleet from Dunkirk, of which he took three veſſels, but fell himſelf in the action. He was interred with great ſolemnity at Delft, where a ſplendid monument was erected to his memory. Moreri.

HEINASE, among *Sportſmen*, a roe-buck of the fourth year.

HEINAVESI, in *Geography*, a town of Sweden, in the government of Kuopio; 37 miles S.E. of Kuopio.

HEINECIUS, JOHN GOTTLIER, in *Biography*, was born at Eiſenberg in 1681. He was early devoted to the ſtudy of theology, and was for a time a preacher at Goſlar, when he applied himſelf moſt diligently to the ſcience of juriſprudence. In 1703 he was appointed profeſſor of philoſophy at Halle, and ſoon after obtained the degree of doctor of laws. In 1720 he was promoted to be public profeſſor of law, with the title of counſellor of ſtate, but in 1724 he removed to Franeker, where he was made profeſſor of the ſame ſcience. After this he was public profeſſor at Frankfort, and in 1733 he removed again to Halle, where he died in 1741, leaving behind him very many works as memorials of his great learning; among theſe may be mentioned "Syntagma Antiquitatum Juriſprudentiam illuſtrantium, ſecundum Ordinem Inſtitutionum Juſtiniani digeſtum:" "Elementa Juris Naturæ et Gentium:" this laſt was tranſlated into Engliſh by Dr. Turnbull. Heinecius was a man of great diligence as well as erudition; and his works, on account of the excellence of the ſtyle, and the extenſive knowledge of antiquities diſplayed in them, were well and generally received.

HEINECIUS, JOHN MICHAEL, brother to the preceding, took his degree of maſter of arts at Jena in 1696. He ſtudied the Oriental languages at Frankfort on the Mayne, under the celebrated Ludolph, in whoſe houſe he reſided, and by whoſe advice he went afterwards to Gieſſen, to attend the lectures of ſome other celebrated profeſſors. In 1699 he accepted an invitation of becoming deacon of the church of St. Peter and St. Paul at Goſlar, where he obtained great reputation by his learned works. After nine years reſidence at Goſlar, he was appointed paſtor of St. Ulrich's church at Halle. Here he died in 1722. His numerous works are written partly in Latin, and partly in the German language, of which we may notice his "Account of the Antiquities of Goſlar and the neighbouring Places:" and his view of the ancient and modern Greek church. Gen. Biog.

HEINICHEN, GEORGE, a young Saxon compoſer, who, travelling through Italy in 1728, ſet two operas for the Venetian theatre, which were very favourably received, at a time when Haſſe and Vinci had refined the taſte of that city.

HEINICHEN, JOHN DAVID, a German muſician of great eminence, in the ſervice of the electoral king of Poland. Being appointed maeſtro di cappella at that court, after he had made the tour of Italy, he drew up a treatiſe on thorough-baſe or accompaniment with ſo much intelligence, clearneſs, and ſcience, that Marpurg ſtyles him the Rameau of Germany. He taught Quantz compoſition; and compoſed for the Italian opera at Dreſden, when Seneſino was the principal ſinger there, between whom there was a quarrel, in conſequence of which, Seneſino engaged with Handel to ſing at the Royal Academy in London. Heinichen died in 1729, the ſame year that the quarrel happened between Handel and Seneſino in London.

HEINOLAX, in *Geography*, a town of Sweden, in the province of Tavaſtland; 55 miles E. of Tavaſthus.

HEINSBERG, a town of France, in the department of the Roer, and chief place of a canton, in the diſtrict of Aix-la-Chapelle; 10 miles S. of Ruremond. The place contains

tains 1333, and the canton 18,331 inhabitants, in 32 communes. N. lat. 51° 2'. E. long. 6° 1'.

HEINSIUS, DANIEL, in *Biography*, was born at Ghent in 1580. On account of the troubles in the Low Countries, his father, who was attached to the principles of the reformation, took his family firſt to England, and then to Holland, where he ſettled at the Hague. Here and at Zealand Daniel received his education. At a very early age he diſplayed conſiderable talents; he began to make Latin verſes before he underſtood the rules of proſody, and when he was ten years old, he compoſed an elegy of much merit on the death of a play-fellow. At the age of fourteen he was ſent to ſtudy the law at Franeker, but he preferred Greek literature, and made a rapid progreſs in it. He next removed to Leyden, where he had the advantage of Scaliger's inſtructions and friendſhip. At the age of twenty he began to read public lectures at Leyden on the claſſics. He was afterwards appointed profeſſor of politics and hiſtory, and made ſecretary and librarian to the univerſity. In 1619 he was ſecretary to the ſtates of Holland at the ſynod of Dort. He had conferred upon him the title of counſellor to Guſtavus Adolphus, and that of knight of St. Mark at Venice. He was offered conſiderable preferment by pope Urban VIII. if he would ſettle at Rome, but he preferred remaining at Leyden, where he died in 1655. As a critic and commentator he publiſhed notes on Silius Italicus, and the New Teſtament. He gave new editions of Horace, Seneca's tragedies, Heſiod, Maximus Tyrius, Theocritus, Theophraſtus, and others. As an original author his Latin poems are moſt eſteemed, and gave him the reputation of being one of the beſt compoſers of Latin verſe among his contemporaries. Theſe have gone through many editions. He pronounced on various occaſions Latin orations, which were collected and publiſhed at Leyden. Moreri.

HEINSIUS, NICHOLAS, ſon of the preceding, was born at Leyden in 1620, and having the advantage of his father's inſtructions, he was, at the age of ſeventeen, connected with ſome of the principal ſcholars of his time. When he was in his twenty-firſt year he came over to England, for the purpoſe of collating ſome MSS. in the univerſity libraries. He ſpent many years in his travels on the continent, ſearching into the libraries of the principal cities, and making ſuch collections as he thought might be moſt uſeful to him. He publiſhed ſome Latin poems which attracted the notice of Chriſtina, queen of Sweden, whom he viſited, and who honoured him with a very favourable reception. Upon his return he ſet out on a new journey through France and Italy, for the purpoſe of purchaſing MSS. and medals for Chriſtina. After this he was nominated by the United Provinces to the poſt of reſident at the court of Sweden, with a ſalary. In 1655 he returned to Holland, on occaſion of the death of his father, and received the appointment of ſecretary to the city of Amſterdam. An unfortunate law-ſuit obliged him to reſign this office, and he was again appointed reſident at Sweden, and in 1669 he was made envoy-extraordinary to Muſcovy. In 1675 he retired to Utrecht, and thence he went to Vienna where he ſpent the remainder of his life. He died in 1681, and was interred in his father's tomb at Leyden. His poems paſſed through many editions, but his beſt work conſiſts of his "Elegies," and a panegyric on queen Chriſtina. Like his father he edited new impreſſions of ſeveral of the claſſics, and after his death were publiſhed his notes upon Valerius Flaccus, Silius Italicus, Petronius, Phœdrus, Q. Curtius, Tibullus, and Tacitus. An edition of Virgil, with his notes, was publiſhed at Amſterdam in 1746. Burmann wrote his life, and publiſhed his Latin letters, which are highly praiſed for purity of ſtyle.

HEIR, formed of the Latin *hæres*, of the verb *hærere*, *to ſtick, remain faſt, be near, follow immediately*, &c. in the *Civil Law*, denotes the perſon who ſucceeds to the whole eſtate and effects of another, whether by right of blood or of teſtament. See DESCENT.

The inſtitution of an heir is a circumſtance neceſſary to the validity of a teſtament.

There are two principal kinds of heirs, the *apparent* and *preſumptive*.

HEIR *Apparent*, is he on whom the ſucceſſion is ſo ſettled, that he cannot be ſet aſide without altering the laws of ſucceſſion: or, whoſe right of inheritance is indefeaſible, provided he outlives the anceſtor; as the eldeſt ſon or his iſſue, who muſt by the courſe of the common law be heir to the father, whenever he happens to die.

HEIR *Preſumptive*, is one who, if the anceſtor ſhould die immediately, would, in the preſent circumſtances of things, be his heir; but whoſe right of inheritance may be defeated by the contingency of ſome nearer heir being born; as a brother or nephew, whoſe preſumptive ſucceſſion may be deſtroyed by the birth of a child; or a daughter, whoſe preſent hopes may be cut off by the birth of a ſon. Nay, even, if the eſtate hath deſcended, by the death of the owner, to ſuch brother or nephew, or daughter; in the former caſes the eſtate ſhall be taken away by the birth of a poſthumous ſon. Bro. *tit. Deſc.* 58.

HEIR, in *Common Law*, is he who ſucceeds, by right of blood, to any man's lands, or tenements in fee.

For nothing paſſes in common law, *jure hæreditatis*, by right of inheritance, but fee.

By common law, therefore, a man cannot be heir to goods or chattels: for *hæres dicitur ab hæreditate*, it is the inheritance denominates the heir.

Every heir having lands by deſcent, is bound by the acts of his anceſtors, if he be named; it being a maxim, that *qui ſentit commodum, ſentire debet et onus*. But though ever ſo much land come to him from ſuch anceſtors by gift in tail, or conveyance of the father, and not by deſcent, he is no way chargeable; and the caſe is the ſame in all other eſtates, except fee-ſimple.

Eſtates are tranſmitted from the anceſtor to the heir, according to certain rules or canons of inheritance, for which ſee DESCENT, *Collateral*.

Thoſe that are incapable of being heirs are baſtards, aliens, and perſons attained for treaſon or felony, (ſee ATTAINDER); but idiots and lunatics, perſons excommunicated, or that are attainted in a *premunire*, outlaws in debt, &c. are capable of being heirs.

The heir is favoured by common law; for not only land, but rent not due and in arrear at the death of the anceſtor, ſhall go to the heir; ſo corn ſown by a tenant for years, where his term expires before his corn is ripe, and every thing faſtened to the freehold, timber-trees, deeds belonging to the inheritance, deer, conies, pigeons, fiſh, &c. go to the heir. If an heir hath made over lands fallen to him by deſcent, execution ſhall be had againſt him to the value of the land, &c. if it be not ſold *bonâ fide* before the action brought, in which caſe there is a ſaving by the ſtat. 3 & 4 Will. & Mary, cap. 14. and it ſhall be tried by a jury, whether the heir hath ſuch lands, and what is their value, in order to make the heir anſwerable. A creditor may ſue either the heir, executor, or adminiſtrator, each of whom is chargeable; but when an heir, on being ſued, pays his anceſtor's debts, he ſhall be reimburſed by the executors of ſuch anceſtors, if he has aſſets in his hands. The heir can force the adminiſtrator to pay debts out of the perſonal eſtate, in order to preſerve the inheritance free; and where an executor

cutor has aſſets, he is compellable in equity to redeem a mortgage and diſcharge debts.

Moveables, or chattels immoveable, are given by teſtament, to whom the teſtator thinketh fit; otherwiſe they lie at the diſpoſition of the ordinary, to be diſtributed as he in conſcience likes beſt.

HEIR *Laſt*. See LAST *Heir*.

HEIR-*loom*, formed of *heir* and the Saxon *loom*, denoting *limb* or *member*, in our *Law-books*, ſignifies ſuch goods and perſonal chattels as are not inventoried after the owner's deceaſe, but go by ſpecial cuſtom to the heir along with the inheritance, and not to the executor of the laſt proprietor.

"Conſuetudo hundredi de Stretford, in com. Oxon. eſt quod hæredes tenementorum infra hundredum predict. exiſten. poſt mortem anteceſſorum ſuorum habebunt, &c. principalium, Anglice an heir-loome, *viz.* de quodam genere catallorum, utenſilium, &c. optimum plauſtrum, optimam carucam, optimam ciphum, &c." Coke on Littleton, 388.

Heir-looms are generally ſuch things as cannot be taken away without damaging or diſmembering the freehold; otherwiſe, the general rule is, that no chattel intereſt whatſoever ſhall go to the heir, notwithſtanding it is expreſsly limited to him and his heirs, but ſhall be veſted in the executor. (Co. Litt. 388.) But deer in a real authorized park, fiſhes in a pond, doves in a dove-houſe, &c. though in themſelves perſonal chattels, yet are ſo annexed to, and ſo neceſſary to the well-being of the inheritance, that they ſhall accompany the land wherever it veſts, by either deſcent or purchaſe. (Co. Litt. 8.) Thus, the ancient jewels of the crown are held to be heir-looms; becauſe they are neceſſary to maintain the ſtate, and ſupport the dignity of the ſovereign for the time being. Charters likewiſe, and deeds, court-rolls, and other evidences of the court, together with the cheſts in which they are contained, ſhall paſs together with the land to the heir, in the nature of heir-looms, and ſhall not go to the executor. (Bro. *abr. tit. Chattels*, 18.) By ſpecial cuſtom alſo, in ſome places, carriages, utenſils, and other houſhold implements, may be heir-looms (Co. Litt. 18. 185.); but ſuch cuſtom muſt be ſtrictly proved. On the other hand, by almoſt general cuſtom, whatever is ſtrongly affixed to the freehold or inheritance, and cannot be ſevered from thence without violence or damage, is become a member of the inheritance, and ſhall thereupon paſs to the heir; as chimney-pieces, pumps, old fixed or dormant tables, benches, and the like. (12 Mod. 520.) Other perſonal chattels, that deſcend to the heir in the nature of heir-looms, are a monument or tombſtone in a church, or the coat-armour of his anceſtor there hung up, with the banners and other enſigns of honour ſuited to his degree. (12 Rep. 105. Co. Litt. 18.) Pews in the church are ſomewhat of the ſame nature, which may deſcend by cuſtom immemorial from the anceſtor to the heir (3 Inſt. 202. 12 Rep. 105.) Heir-looms, though they be mere chattels, cannot be deviſed away from the heir by will; but ſuch a deviſe is void, even by a tenant in fee-ſimple. (Co. Litt. 185.) For though the owner might, during his life, have ſold or diſpoſed of them, as he might of the timber of the eſtate, ſince, as the inheritance was his own, he might mangle or diſmember it as he pleaſed; yet they being at his death inſtantly veſted in the heir, the deviſe (which is ſubſequent, and not to take effect till *after* his death) ſhall be poſtponed to the cuſtom, whereby they have already deſcended. Blackſt. Com. book ii.

HEIRAN, in *Geography*, a town of Arabia, in the province of Yemen; 36 miles S. of Abu Ariſeh.

HEIRESS, *Stealing of an*. See FORCIBLE *Abduction*.

HEIRS, in *Rural Economy*, a term occaſionally applied to the young trees in coppice-woods.

HEISHER ISLANDS, in *Geography*, two ſmall iſlands of Scotland; 15 miles N. of North Uiſt iſland. N. lat. 57° 46'. W. long. 7° 51'.

HEISS, JOHN, in *Biography*, reſident for the elector palatine at the court of France, is known, and mentioned here, for a hiſtory of the German empire, firſt publiſhed at Paris in 1684, in two vols. 4to. A new edition of it was printed by M. Vogel in 1731 in three volumes. Heiſs died at Paris in 1688. His work has been charged with the want of fidelity, but it is often referred to. Moreri.

HEISTER, LAURENCE, a celebrated phyſician, ſurgeon, and anatomiſt, who has alſo rendered himſelf conſpicuous among botaniſts by his objections to the ſyſtem and principles of Linnæus, at a time when they were making the greateſt progreſs in the general eſtimation, was born at Frankfort on the Maine, in 1683. He was educated in ſeveral German univerſities, and in the year 1706 ſpent ſome time in the ſtudy of anatomy and ſurgery at Amſterdam under Ruyſch, then ſo famous for his diſſections and anatomical preparations. In the following year he went to ſerve as a ſurgeon in the Dutch camp in Brabant; devoting the ſubſequent winter to further improvement, under Boerhaave and his eminent colleagues, who at that time attracted ſtudents from all parts to the univerſity of Leyden, where Heiſter took his degree. Returning afterwards to the camp, he was, in 1709, appointed phyſician-general to the Dutch military hoſpital. The experience he thus acquired, turned to account by his great application and acuteneſs, raiſed him to a diſtinguiſhed rank in the theory and practice of ſurgery, eſpecially as he had a genius for mechanics, and was by that means enabled to bring about great improvements in the inſtrumental branch of his art. In 1710 he became profeſſor of anatomy and ſurgery at Altorf in the little canton of Uri, and rendered himſelf celebrated by his lectures and writings. Ten years afterwards a more advantageous ſituation offered itſelf to him at Helmſtad, where he became phyſician, with the title of Aulic counſellor, as uſual, to the duke of Brunſwick, as well as profeſſor of medicine, and afterwards of ſurgery and botany, in that univerſity. Here he continued till his death, which happened in 1758, at the age of 75. The czar Peter invited him to Ruſſia, but he was too comfortably ſituated in Germany, where the favour of ſeveral ſovereigns already ſhone upon him at an early period, to accept the invitation.

Heiſter continued, from time to time, to publiſh a number of books relating to anatomy and ſurgery, to ſeveral of which he ſupplied figures drawn by his own hand. Among theſe, his moſt diſtinguiſhed work is the *Compendium Anatomicum*, an octavo volume, firſt printed in 1717, which became quite a claſſical book, ſuperſeding all that had been previouſly in uſe in the ſchools. It went through numerous editions, with ſucceſſive additions and improvements, and was tranſlated into moſt of the modern languages. In the preface he labours to expoſe the defects of the principal author who had hitherto been in popular uſe, Verheyen; cenſuring him, not unjuſtly, for his omiſſion of ſome of the principal diſcoveries of divers eminent Engliſh and Italian anatomiſts, and others. Indeed his criticiſms of this author are ſo well ſupported by references, and authoriſed by fact, that we cannot wonder at his having entirely driven him off the ſtage. Heiſter's *Compendium* is very excellent for its conciſeneſs and clearneſs, both as an anatomical and phyſiological ſchool-book. Nor did his "Inſtitutions of Surgery," publiſhed in German in 1718, procure him leſs decided authority in that line. The book was tranſlated into Latin, and moſt of the modern languages of

of Europe, and went through numerous editions. He wrote alſo ſome works on the theory and practice of medicine, in which his opinions are formed on the mechanical principles of the Boerhaavian ſchool, chemiſtry being ſcarcely more conſidered in the phyſiological ſpeculations of that day, than the agency of the vital principle, both which have made ſo great a figure ſince. A valuable practical work of Heiſter's, a collection of medical, ſurgical, and anatomical obſervations, in quarto, is well known in this country by an Engliſh tranſlation.

Heiſter ſeems early to have had a taſte for botany, and to have collected plants, as Haller obſerves, in his various journeys. This taſte enabled him to fill the botanical chair at Helmſtad with credit and ſatisfaction, and he paid great attention to the garden there, which he much enriched, and of which he publiſhed a catalogue in 1734, in 8vo., arranged alphabetically. At the end of this little volume he eſtabliſhes 16 new genera, moſtly named after botaniſts, or elſe without any ſound principles of nomenclature. Still leſs are their definitions well choſen. Heiſter loſt ſight of the only clue to ſolid botanical characters, the fructification, looſely regarding the whole plant, and chooſing his diſcriminative marks from the moſt vague and trifling ſources. Thus, he makes *Amaranthus tricolor* a genus, chiefly on account of its coloured leaves, and he names this new genus *Pſittacus*, becauſe its hues reſemble a parrot; not conſidering that the name is already eſtabliſhed in zoology, and that any perſon might as well make a genus of a white roſe, and call it a *Horſe*, becauſe *ſome* horſes are white. His *Stiſſeria* indeed is a good genus, the *Stapelia* of Linnæus and others, but without any character, and he may be content with neglect in this inſtance, if he eſcapes criticiſm in the reſt. His firſt botanical publication, *De Collectione Simplicium*, was the inaugural diſſertation of one of his pupils named Rabe, printed in 1722. This, by Haller's account, is ſtill more unworthy of a philoſopher. If he had written nothing elſe, his botanical labours ſhould have been conſigned to oblivion, in conſideration of his merits in a more important practical ſcience; but his ſubſequent works rank him as an original writer, even on the ſubject of vegetables. If we differ from him, we reſpect him as a man who thought for himſelf, and who perhaps might have thought better, had he been favoured with leiſure to look deeper, and not been warped by preconceived ideas. In 1732 he publiſhed a diſſertation on the "Uſe of the Leaves" in founding genera of plants, preferring thoſe parts for a natural arrangement, on account of the obſcurity and difficulty attending thoſe of the flower. Our ideas on this ſubject will be found under the article CONRAD GESNER, and are ſufficiently familiar to all who have, at this day, ſtudied botany at all.

In Auguſt, 1741, our author came forth as the profeſſed adverſary of Linnæus, in the inaugural diſſertation of one of his pupils named Goeckel, entitled *Meditationes et Animadverſiones in novum Syſtema Botanicum ſexuale Linnæi.* This very pupil ſeems, by a note in p. 50, to have been choſen for the purpoſe, becauſe his maternal grandfather, named Lochner, had written a ſplendid book on the *Ananas*, or Pine-apple, and Linnæus, if he choſe to alter the barbarous name, ought, it ſeems, to have called the genus *Lochneria*, whereas he termed it *Bromelia!* Such a reaſon might as well have been kept out of ſight. But the arguments by which the learned profeſſor and his pupil attempt to prove the poſition they aſſume, that the "method of Linnæus is extremely difficult, very doubtful, and uncertain," are not more cogent. They declare that the ſtamens and piſtil of two ſpecies of *Aloe*, the *margaritifera* and another, appeared ſo compreſſed, conſtricted, and confuſed, that they could make out nothing of their ſhape or number; that they could ſee nothing of the ſtamens or piſtils of papilionaceous flowers, without ſeparating the petals, of which it appears they never thought till thoſe parts fell of themſelves. They found no leſs difficulty in the common Chickweed, *Alſine media* (*Stellaria media*, Fl. Brit. 473. Engl. Bot. t. 537), of which, when they attempted to examine the ſtamens, they could indeed perceive the anthers, but ſo entangled together, that they could ſcarcely diſcern any one ſtamen clearly and diſtinctly, much leſs count the whole! So much for their objections to the Linnæan ſyſtem of arrangement! and we have only to congratulate ourſelves that their countryman Hedwig was bleſt with more acuteneſs of bodily and mental viſion. Some objections, relative to the natural order to which the *Alſine* belongs, concerning the variableneſs or anomalies of number in that order are more to the purpoſe, but it is really aſtoniſhing that any man ſhould have ſufficiently examined nature and the works of Linnæus to find out this particular difficulty, and yet not have been ſtruck with the ſagacity and ingenuity with which he ſtruggled againſt it. A natural philoſopher, in the honeſt purſuit of truth, contending with thoſe intricacies of nature which the human intellect is competent but partially to unravel, is entitled to a ſhare of the reſpect ſo juſtly due to a good man ſtruggling with adverſity, and a well-turned mind will, in neither caſe, withhold its admiration or aſſiſtance. Heiſter is not much more candid in his criticiſms of the Linnæan nomenclature, for as he could not perceive the benefit of eſtabliſhing correct genera, on principles derived from the fructification, it is no wonder he was blind to the advantages of naming ſuch with ſymmetry and conſiſtency. If there be, as we muſt allow, ſome juſtice in his objection to a ſubſtitution of the Linnæan ſpecific definitions, often extending to 12 words, in place of the old more compendious pharmaceutical names, that objection has been ſubſequently removed by the invention of trivial or ſpecific names.—Another diſſertation of Heiſter's, publiſhed in Oct. 1741, *de Nominum Plantarum Mutatione utili ac noxia*, is a more diffuſe and elaborate attack on the nomenclature of the great Swediſh teacher, whom however he terms "a moſt diligent and moſt valuable botaniſt." Nor does it appear that he was inſtigated to theſe attacks by any perſonal enmity, nor by any more extraordinary flow of bile than was uſual among controverſialiſts, of that day at leaſt. The portrait of Heiſter, very well executed, which is prefixed to his *Compendium Anatomicum*, has an animated countenance, not entirely deſtitute of eagerneſs or irritability. Whatever he purſued, he purſued with ardour, and perhaps as he advanced in age, ſeated in profeſſional ſtate, he grew more pertinacious in his opinions. Hence his ſubſequent attacks on Linnæus are marked with more vehemence, but proportionably, as uſual, with leſs reaſon, and therefore we paſs them over here. In 1748, notwithſtanding his diſlike to the Linnæan principles, he publiſhed a *Syſtema Plantarum Generale ex fructificatione, cui annectuntur regulæ ejuſdem, de Nominibus Plantarum, a Celeb. Linnæi longè diverſæ.* This ſyſtem is allied to that of Boerhaave, and by no means remarkable for originality or ingenuity, nor, though it takes into conſideration many particulars of general habit or ſtructure, is it more natural than the profeſſedly artificial ſyſtem of Linnæus. Though he will not allow his antagoniſt (if we may ſo call a perſon who never anſwered or cenſured him) to contrive new names for new genera, or for original ideas, he himſelf changes old ones without ſcruple, and would call *Briza, Tremularia; Coix, Lacrymaria; Feſtuca, Feſtucaria; Meſembryanthemum, Ficula; Galanthus, Nivaria;* &c.

We ſhall conclude with mentioning a very ſplendid publication of Heiſter in folio, in 1753, in which he deſcribes the *Amaryllis*

Amaryllis orientalis of Linnæus, which flowered with him, perhaps for the firſt time in Europe, three years before. This he names *Brunſvigia*, after his patron and ſovereign, and diſplays its magnificence in three coloured plates. The ſame plant has ſince bloſſomed at Schoenbrun, and is figured by Jacquin, but though its bulbs are not rare, we have never heard of their flowering any where elſe. Haller. Bibl. Bot. Aikin's Gen. Biogr. Heiſter's works. S.

HEISTERIA, in *Botany*, ſo named by Jacquin, in honour of Dr. Laurence Heiſter; ſee that article. Another plant had received this name from the hand of Linnæus himſelf, in the *Hortus Cliffortianus*, notwithſtanding the unfavourable diſpoſition of Heiſter towards the ſexual ſyſtem, and the Linnæan improvements in general; but it was afterwards properly reduced to *Polygala*, and now ſtands as P. *Heiſteria*. The preſent is a more certain and very fine genus, of which its founder knew but one ſpecies, though we are poſſeſſed of two more.—Jacq. Amer. 126. Linn. Gen. 214. Schreb. 291. Willd. Sp. Pl. v. 2. 579. Mart. Mill. Dict. v. 2. Juſſ. 260. Lamarck. Dict. v. 3. 81. Illuſtr. t. 354.—Claſs and order, *Decandria Monogynia*. Nat. Ord. *Holeraceæ*, Linn. *Aurantiæ*, Juſſ.; but we preſume to think one is not nearer the truth than the other, and that Lamarck has rightly ſuggeſted the affinity of this genus to ſome of Juſſieu's *Terebintaceæ*, in which order we would place it.

Gen. Ch. *Cal.* Perianth of one leaf, inferior, bell-ſhaped, five-cleft, acute, ſmall, permanent; in the fruit enlarged, coloured, with blunted points. *Cor.* Petals five, ovate, concave, acute, ſpreading. *Stam.* Filaments ten, flat, ovate, acute, erect, five of them ſhorter than the reſt; anthers roundiſh *Piſt.* Germen roundiſh, depreſſed; ſtyle ſhort, erect; ſtigma blunt, four-cleft. *Peric.* Drupa oblong, Abrupt at the ſummit, ſtanding on the greatly enlarged and coloured calyx. *Seed.* Nut oval, obtuſe, with a kernel of the ſame ſhape.

Eſſ. Ch. Calyx in five ſegments, permanent, inferior. Petals five. Drupa ſtanding on the enlarged coloured calyx.

1. H. *coccinea*. Linn. Sp. Pl. 1663. Jacq. Amer. 126. t. 81. (Borbonia fructu oblongo nigro, calyce coccineo; Plum. Gen. 4.)—Leaves elliptic-oblong, rounded at the baſe, ſhining. Flowers axillary. Calyx of the fruit widely ſpreading, with ſhallow lobes.—Native of deep woods, near torrents, in the iſland of Martinico, flowering in February and March, and bearing fruit in June. Jacquin's own ſpecimen, the only one we have ever ſeen, is preſerved in ſir Joſeph Banks's herbarium, and has fruit, but now flowers. Lamarck repreſents the latter in his plate, which Jacquin does not, and therefore it ſhould ſeem that ſome ſpecimens have been acquired by the French, ſince the time of Plumier or Jacquin, though few plants are leſs known to botaniſts. of Linnæus never ſaw the *Heiſteria* at all. We know not why he firſt wrote Plumier's ſynonym into his own copy of the *Species Plantarum*, and then eraſed it. There ſeems to be no doubt of this ſynonym, though Plumier confounded, under one genus with the preſent plant, the *Laurus Borbonia* of Linnæus, which is figured in his *Nov. Gen.* t. 2. at the bottom.—*Heiſteria coccinea* is deſcribed by Jacquin as an inelegant branching *tree*, about 20 feet high. The *leaves* are about ſix inches long, alternate, oblong, inclining to elliptical or ovate, with an oblique point, entire, rounded at the baſe, ſmooth, ſhining, having a midrib which ſends off ſeveral tranſverſe veins, interbranching towards the margin. *Footſtalks* ſhort and thick, without *ſtipulas*. *Flowers* axillary from ſome of the uppermoſt leaves, ſolitary, ſmall, white, their ſtalks ſcarcely ſo long as thoſe of the leaves, except when in fruit. *Calyx* of the flower ſmall and green; of the fruit greatly enlarged, ſpreading, ſcarlet, its border in five roundiſh, ſhort, and very blunt ſegments. *Fruit* ovate or cylindrical, blunt, about as long as the calyx, in the centre of which it ſtands. Jacquin ſays nothing of its colour, but if Plumier's ſynonym be right, the *drupa* is black. The French inhabitants of Martinico call it *Bois perdrix*, Partridge-tree, becauſe a kind of wild pidgeon, which they miſname a partridge, is very fond of the fruit.

2. H. *cauliflora*.—Leaves oblong, ſomewhat obovate, tapering at the baſe. Flowers from the ſtem and naked branches. Calyx of the fruit cloſed, deeply lobed.—Gathered in the Dutch ſettlements at Guiana by Mr. Alexander Anderſon, one of whoſe ſpecimens was given us by ſir Joſeph Banks in 1791. This is a lofty *tree*, bearing its flowers and fruit from the naked parts of the branches and ſtem. *Leaves* alternate, crowded about the tops of the branches, ſix inches or more in length, of a narrow obovate or oblong form, ſomewhat pointed, entire, ſlightly wavy, light green, ſmooth, but ſcarcely ſhining, reticulated with innumerable tranſverſe veins between the great ones, tapering down at the baſe into a ſhort thick *footſtalk*, without *ſtipulas*. Of the *flowers* we know nothing. The *fruit* is ſolitary, ſcattered, drooping, on a ſhort ſtalk, its *calyx* apparently coloured like the foregoing, but larger, with much deeper ſegments, which cloſe about the *drupa*, and whoſe edges are folded back.

3. H. *parvifolia*.—Leaves ovate, pointed, ſhining. Flowers axillary. Calyx of the fruit widely ſpreading, with deep ovate lobes.—Diſcovered at Sierra Leone by Dr. Afzelius, to whom we are obliged for ſpecimens in fruit. The *branches* are in ſome degree compreſſed and two-edged. *Leaves* alternate, ſcarcely two inches long, ovate, with a longiſh blunt point, entire; rounded at the baſe; the edge a little reflexed; ſmooth and ſhining, eſpecially above, with almoſt imperceptible veins. The *flowers* grow from little ſcaly axillary buds, and, from the ſcars that remain, ſeem to be three or four from each bud, one of them only remaining to form fruit. The latter is rather drooping, on a ſhort thick ſtalk. Its *calyx* red, ſpreading, about an inch in diameter, being about half the ſize of the laſt, very deeply divided into five ovate obtuſe lobes, the ſinuſes between which are reflexed. *Drupa* ovate, pale in the dry ſtate, rather ſhorter than the lobes. The dried leaves have a bitteriſh, rather acrid, flavour, confirming what is ſaid above of the natural affinity of the genus, and there is ſome analogy between the fleſhy-coloured calyx of *Heiſteria*, and the pulpy receptacle of the fruit of *Anacardium* and *Semecarpus*. We have no ſufficient opportunity of examining, but there ſeems reaſon to doubt whether the fruit be a real drupa, or only a capſule with a fleſhy coat of no great thickneſs. S.

HEITERNSHEIM, in *Geography*, a town of Germany, in a principality of the ſame name, in the circle of the Upper Rhine; 10 miles S. of Briſach.

HEITSBURY, Heytesbury, or *Heightſbury*, a borough-town and pariſh in the hundred of the ſame name, county of Wilts, England, is ſeated in a valley, near the S.W. extremity of Saliſbury plain. It is an ancient borough by preſcription, and ſends two members to parliament. The firſt return was 27 Henry VI. The right of election is in the burgage-holds, which are about fifty in number, and were till lately the property of the duke of Marlborough and ſir W. P. A. A'Court, bart. but the latter, having purchaſed the Marlborough intereſt, has the two ſeats in his own nomination. This town was ſome time the reſidence of the empreſs Maud, when ſhe contended with Stephen for the crown of England. In the reign of Edward III. it belonged to Bartholomew lord Burgherſh, and was afterwards

wards the abode of the barons Hungerford. Thomas, lord Hungerford, about the year 1400, built or greatly enlarged the church, which was collegiate before the year 1300. Walter, lord Hungerford, lord high treaſurer of England, founded an hoſpital for twelve poor men and one woman; and alſo built a houſe for a ſchoolmaſter, who was to be a prieſt, and not only teach grammar, but overlook the poor men. Margaret, the widow of lord Walter, obtained a licence from king Edward IV. to perfect this charity and ſettle a chaplain in it, to celebrate divine ſervice in the pariſh church, for the ſouls of herſelf and others. The church is collegiate, having four prebends in it, belonging to the cathedral church of Saliſbury. The building is ſpacious and ſtrong, in the form of a croſs, in the centre of which is a tower. The town, which conſiſts chiefly of one ſtreet, was almoſt entirely burnt down in the year 1766, ſince which it has been rebuilt to its former extent, and greatly improved in its appearance and reſpectability, principally owing to the introduction of the clothing manufactories, which are now carried on to a conſiderable extent. Here were formerly a weekly market and two fairs yearly; the firſt has been long diſcontinued; and there is only one of the latter, which is held on the 14th of May, for cattle, ſheep, &c. Heyteſbury is 92 miles diſtant from London; the population, returned in the year 1801, was 1072; the number of houſes 210. Sir W. P. A. A'Court has a ſeat cloſe to the town.

This town was the reſidence, if not the birth place, of a very worthy man, and valuable antiquary, William Cunnington, who laudably devoted his leiſure hours to the inveſtigation of the barrows, encampments, &c. which are very numerous on Saliſbury-plain, and in the neighbourhood of this town. The reſult of theſe reſearches has been laid before the public by ſir Richard Colt Hoare, bart. in a folio book, entitled "Ancient Wiltſhire." This very curious work furniſhes much valuable and intereſting information relating to the contents of barrows, and the cuſtoms of the early inhabitants of Britain. Under the articles STONEHENGE, TUMULI, and WILTSHIRE, we ſhall have occaſion to revert to it again. In a valley between this town and Warminſter, in a meadow called Pitmead, was diſcovered, in the year 1786, the foundation, with teſſellated pavements, &c. of a Roman villa; and in 1800 other veſtiges of the Romans were found here. At the end of this valley is a lofty ridge of the plain, on which are the earth-works of two encampments. Theſe are of great extent; and, from their commanding ſituations, muſt have been almoſt impregnable. One of theſe, called Scratchbury caſtle, comprehends an area of forty-one acres of land: the other, named Battleſbury caſtle, has a treble intrenchment. Britton's Beauties of Wiltſhire.

HEL RIVER, in Cornwall, falls into Falmouth bay at Little Dinnis, and from thence, about $5\frac{1}{2}$ miles W. to Gweek, near Mawgan, is navigable for ſmall veſſels.

HELAOUA, a town of Nubia, and the laſt ſubject to the Ottoman Porte; it has a conſiderable garriſon, and pleaſant environs, which abound with coloquintida and ſenna.

HELCESAITES. See ELCESAITES.

HELCOMA, HELCOS, HELCOSIS, } an ulcer, or ulceration.

HELCYDRION, from ἕλκος, an *ulcer*, a ſmall ulcerated puſtule.

HELCYSMA, of ἕλκος, a word uſed by ſome of the old writers, to ſignify the ſcoriæ of ſilver, called alſo by ſome encauma. Dioſcorides ſays, this has the ſame virtues with the molybdæna, and that it was in his time uſed like that in plaſters.

HELCYSTER, of ἕλκω, *I draw*, in *Surgery*, a hook uſed to extract the fœtus in difficult parturition.

HELDAZOO, in *Geography*, a ſmall iſland of Scotland, near the S. coaſt of Shetland. N. lat. 60° 13'. W. long. 1° 43'.

HELDBURG, a town of Germany, in the principality of Coburg; 8 miles W. of Coburg.

HELDER, a fortreſs of North Holland, at the entrance of the Texel, erected for the defence of Mars-Diep; taken by the Engliſh under ſir Ralph Abercrombie, Aug. 28, 1799; 24 miles N. of Alcmaer. N. lat. 53° 2'. E. long. 42° 34'.

HELDRUNGEN, a town of Germany, belonging to the principality of Querfurt, in a ſmall ſtream near the Unſtreitt: near it are two other towns, *viz.* "Feſtury-Heldrungen" and "Ober-Heldrungen;" 15 miles W. of Querfurt. N. lat. 51° 17'. E. long. 11° 20'.

HELEGUG, in *Ornithology*, a name by which the people in ſome parts of England call the *anas arctica Cluſii*, a web-footed fowl common on our ſhores. See DUCK.

HELEL, in *Geography*, a town of Africa, in the country of Sugulmeſſa; 40 miles N.W. of Sugulmeſſa.

HELEN, in *Fabulous Hiſtory*, the daughter of Tyndarus, king of Sparta, and Leda, was married to Menelaus, the brother of Agamemnon, and ſtolen from him by Theſeus in the year 1213 B.C. but afterwards reſtored; ſhe was carried off a ſecond time by Paris and taken to Troy, B.C. 1198, which occaſioned the war of *Troy*; which ſee. After the death of Menelaus ſhe was baniſhed to Rhodes, and there hung upon a tree. Temples were erected to her honour.

HELENA, in *Aſtronomy*. See CASTOR and POLLUX.

HELENA, in *Biography*, mother of Conſtantine the Great, was probably the daughter of an innkeeper of Drepanum, in Bithynia. She attracted the notice of Conſtantine Chlorus in one of his journeys, and was afterwards married to him. It was made a condition by Maximian, when he adopted Conſtantius in 292, that he ſhould divorce Helena and take a wife of imperial blood, and from this time ſhe lived in obſcurity till the death of her huſband, and the ſucceſſion of her own ſon Conſtantine, who ever treated her with the reſpect and attachment due to a mother. Upon his converſion to Chriſtianity ſhe followed his example, and became zealous in the new faith. So great was her ſway at this time, that ſhe had the title of Auguſta conferred upon her, was regarded as the empreſs at court and in the armies, and ſhe had the entire diſpoſal of a large revenue. She had the art and influence to keep from all public employments the three half-brothers of Conſtantine, and when her grandſon Criſpus had fallen a ſacrifice to Fauſta his ſtep-mother, ſhe reſolved to avenge the crime, and diſcovered to the emperor the infidelity of that empreſs, which cauſed her deſtruction. In 326 ſhe paid a viſit to the holy places of Jeruſalem, which was the epoch of that memorable event in eccleſiaſtical hiſtory called the *invention* of the true croſs. (See CROSS.) Having cauſed a temple of Venus, built over the ſuppoſed ſcite of the holy ſepulchre, to be demoliſhed, a cavern was diſcovered, in which were depoſited three croſſes, thought to be thoſe on which Chriſt and the two thieves were crucified. Such a treaſure being found out, it was not difficult, by means of feigned miracles, to aſcertain which of the three was that on which the Saviour ſuffered. Inſtantly, the ſacred relic was cut in two, one half being left

with the biſhop of Jeruſalem, and the other ſhe tranſported to her ſon. Helena remained at Paleſtine, and built a church at Bethlehem, which ſhe conſecrated to the ſon of God, and another on the mount of Olives. She then made a progreſs through the chief churches of the Eaſt, ſignalizing in every place her piety and munificence. She died at the age of eighty, in the year 328, was interred in the imperial mauſoleum at Rome, and canonized as a ſaint. Her native place Drepanum was from this time denominated by Conſtantine Helenopolis. Gibbon.

Helena, *St.*, in *Geography*, an iſland of the Atlantic ocean, ſituated in S. lat. 15° 55′. W. long. 5° 49′, within the limit of the S.E. trade-wind, and diſtant 400 leagues from the coaſt of Africa, which is the neareſt continent. Its extreme length is 10½ miles, its breadth 6¾, its circumference about 28 miles, and its ſurface, in acres, 30,300. This iſland, at a diſtance, appears like an abrupt and rugged rock; a nearer approach brings in view the central eminences, diſtinguiſhed by a ſofter outline, clothed with verdure, and towering to the clouds; but on advancing ſtill nearer, the ſcene again changes, and the green ſummits are concealed from ſight by the intervening craggy and ſtupendous cliffs, that ſeem to overhang the ſea. On rounding Munden's point, the eye is ſuddenly relieved by a view of the town ſituated in a narrow valley, between two lofty mountains; and the interſperſion of trees among the white houſes has an effect highly pleaſing and pictureſque. This valley, known by the name of James's valley, is on the N.W. and leeward ſide of the iſland, in which ſituation there is good anchorage from 8 to 25 fathoms; and freſh-water is conveyed in leaden pipes to the wharf, from a ſpring at the diſtance of two miles, which affords a plentiful ſupply. The riſe and fall of the tide at new and full moon ſometimes exceed five feet; and in 1796 the variation of the compaſs was 15° 47′ 30″. After paſſing the draw bridge, the way to the town lies between a line of heavy guns and a double row of trees, of a lively green, and generally in full leaf; the trees being ſpecies of the banian of India. The town is entered by an arched gate-way, under a rampart or terrace, forming one ſide of a parade about 100 feet ſquare. On the left ſide are the government-houſe and main guard-room, the former being incloſed with a wall, reſembling embraſures, and called the caſtle. It contains the governor's habitation, and the offices of government. The church, fronting the gateway, is a neat and not inelegant edifice. The principal ſtreet commences between it and a palliſade, incloſing the company's garden. It conſiſts of 28 houſes, moſt of them neat and well conſtructed, and divides into two other ſtreets; one on the E. leading to that ſide of the country; the other proceeding to the upper part of the valley, where are ſituated the barracks, the new garden, and the hoſpital. In this ſtreet there are many ſhops, well ſtored with European and Indian commodities: but the houſes, in general, are inferior to thoſe in the loweſt part of the town, where the principal inhabitants reſide. The two hills, or ridges, between which the town is ſituated, are Rupert's on the E., and Ladder-hill on the W. The roads by which acceſs is gained to the interior, are formed on the ſides of theſe hills, and the aſcent is ſo eaſy and ſafe, that carts and oxen paſs along without danger or difficulty. On the firſt mile or two, the traveller obſerves little elſe beſides nakedneſs and ſterility, but his curioſity is ſoon gratified by the ſudden proſpect of verdure, woody heights, neat dwellings, and cultivated plantations.

The iſland is unequally divided by a lofty chain, or ridge of hills, running nearly E. and W. in a curved direction, and bending to the S. at each extremity. From this chain alternate ridges and valleys branch off in various directions, but chiefly N. and S. Diana's Peak, towards the E. end of this chain, is the higheſt point of the iſland, and riſes nearly 2700 feet above the level of the ſea. From the ſummit of this peak houſes and plantations, beneath the line of ſight, diverſify the proſpect, and the contraſt of verdant and naked mountains render the ſcene novel, picturesque, and majeſtic. The ſummits and ſides of moſt of the interior heights are wooded with the cabbage-tree of the iſland, the red-wood, (a ſpecies of ebony,) ſtring-wood, dog-wood, and other indigenous trees and ſhrubs. And in leſs elevated ſituations the gum-wood was formerly found in great abundance, but few trees of this kind are now ſeen, except at Long-wood, where they cover a ſurface of nearly 1500 acres. Clear and wholeſome ſprings iſſue from the ſides of almoſt every hill, but they form only inconſiderable rills. The governor's country reſidence, which lies about three miles from the town, is called the Plantation-houſe, and is a well-built, handſome edifice, erected in the years 1791 and 1792.

Thunder, lightning, and ſtorms, rarely diſturb the ſerenity of this mild atmoſphere. In James's town, the thermometer ſeldom riſes above 80°; but in the country the temperature is much more moderate. At the plantation-houſe the ſummer is not ſo hot as in England, 72° being the higheſt point at which the thermometer was obſerved in 1788. The winter alſo is much milder than ours, ranging between 55° and 56° of Fahrenheit. The rain is diſtributed through the different ſeaſons more in the manner of our temperate than of the tropical climates, every month having its ſhare; the ſtormy ſeaſons are July, Auguſt, and September, and February has more rainy days than either of the other months. Cloudy days are very numerous, exceeding thoſe that are bright, in the proportion of almoſt two to one; and this kind of weather is ſuited to paſture and trees, but not to the ripening of European fruit.

Iron ore is ſaid to be found in ſome parts of the iſland, and there are ſome appearances of gold and copper ore. Lime is plentiful and excellent. The ſoil inclines to clay, and loam abounds in ſaline particles, and deſcends to a great depth. The clouds, floating at a certain height in the atmoſphere, ſupply the higher parts of the iſland with moiſture, without imparting any to the low lands; ſo that after a long continuance of drought, the roots of graſs, &c. periſh. Hence, the luxuriance of vegetation increaſes in proportion to diſtance and height from the ſea; and upon the very ſummits of the interior hills oxen are ſeen up to their knees in graſs, and of courſe the upper lands are regarded as the prime paſtures of the iſland. Fruits, particularly vines, figs, oranges, and lemons, ripen beſt in the valleys near the ſea, which are well adapted alſo to the growth of plantains and bananas. From a garden, more interior, but finely watered and ſheltered, of no greater extent than three acres of ground, 24,000 dozen of apples of a large ſize were gathered in one ſeaſon, beſides peaches, guavas, grapes, and figs in abundance. The greater part of the iſland, however, is a barren reluctant waſte. A ſpecies of yam, introduced from Madagaſcar, is cultivated principally in the valleys; and the attention of the farmer has for ſeveral years paſt been particularly directed to the cultivation of potatoes. Cabbages, peaſe, beans, and other vegetables, are raiſed in abundance. The breed of cattle and ſheep on the iſland is originally Engliſh. The beef is of an excellent quality, but ſuch is the demand, that a bullock is ſeldom allowed to attain the age of four years. In ſome ſituations rabbits abound: pheaſants and partridges are numerous, and every garden is enlivened by the notes of the canary-bird. As to fiſh, it has been computed that 76 different ſpecies frequent

quent the coaſt. Whales are frequently ſeen, and between the months of December and March turtle frequent the iſland. The ſhores and vicinity of the iſland abound in ſea-fowl, which breed in the cliffs and rocks around the coaſt.

Upon an average of five years, *viz.* from 1801 to 1805 inclusive, 165 ſhips touch annually at St. Helena, and in war time, the long detention for convoy experienced by large fleets occaſions ſuch an extra conſumption of ſtock and refreſhment, that the mere productions of the iſland itſelf could never be adequate to ſuch exigencies, if it were not amply ſupplied with ſalt meat from England, and of rice from Bengal. In the year 1805, the rates of proviſions were as follow: beef (alive), 6½*d.* per pound, mutton from 14 to 18*d.* do.; pork from 18 to 20*d.* do.; young fowls 9 to 12*s.* each; turkeys 30 to 40*s.* do.; geeſe 25 to 30*s.* do.; ducks 10 to 12*s.* do.; potatoes 8 to 10*s.* per buſhel: milk 4 to 6*d.* per quart; eggs 5*s.* per dozen; mackarel 8*d.* per dozen; turtle and coal-fiſh 8*d.* per pound; conger, conger-eels, cavallaes, ſilver-fiſh, and old wives 3*d.* per pound; ſtumps and ſoldiers 2*d.* each; long-legs 6*d.* do.; &c.

Soon after the firſt ſettlement of St. Helena, indigo, cotton, ſugar-canes, and vines were introduced. Rum, ſugar, wine, and brandy were brought to ſome degree of perfection, and at a more recent period, crops of barley and other grain were raiſed at Long-wood, but afterwards were not found to anſwer. The intrinſic value of St. Helena, conſiſting in its local ſituation, as a place of refreſhment and rendezvous for the homeward-bound ſhips from India, the attention of the Court of Directors has been confined to the objects which moſt conduced to that important purpoſe. Accordingly, every acre inſtead of being devoted to the cultivation of corn, has been applied to raiſing live ſtock, roots, and culinary vegetables. Its waters, vegetables, and climate, ſeem happily adapted to the recovery of ſcorbutic patients; and many ſuch have been reſtored in the hoſpital to perfect health, vigour, and activity.

By the regiſtered returns of the year 1805, the population of the iſland is ſtated at 504 white inhabitants, 1560 blacks, of whom 329 were free; making a total of 2064, excluſive of the garriſon and civil eſtabliſhment of the company. Five thouſand one hundred and eight acres are in the hands of individuals, beſides goat-ranges, which are the out-ſkirts of the iſland, affording the chief ſupply of freſh meat both to the inhabitants and to the hoſpital. Lands, in general, are ſuppoſed to yield a nett profit of between ſeven and eight per cent. The price of labour is high; a carpenter cannot be hired under 6 or 7*s.* a day; the wages of a maſon vary from 4 to 5*s.*; and thoſe of a labourer from 2*s.* to 2*s.* 6*d.*; or to a black man, engaged by the year, from 10 to 20*l.* The value of ſlaves has varied; the ſum of 150*l.* has been paid for a good huſbandman, but a man of bad character may be purchaſed for 30*l.* However, it is hoped, that this kind of traffic is *for ever* aboliſhed.

This iſland compriſes only one pariſh; but for the more regular performance of the county and pariſh officers' duties, it is divided into three diſtricts: *viz.* the eaſt, the weſt, and the ſouth, or Sandy-bay diviſion. There are two churches, one in the town and another in the country. Strangers, whilſt they remain on the iſland, are accommodated in private houſes, at the rate of one guinea per day; for which an excellent table, good wines, and comfortable lodgings are provided.

By repeated charters from the crown of Great Britain, the poſſeſſion of St. Helena is aſſigned in perpetual property to the Eaſt India company as lords proprietors, with powers of ſovereignty and legiſlation. The ſupreme and executive authority within the iſland is veſted in the governor, and a council, compoſed of the lieutenant-governor and ſenior civil ſervant. To this number is occaſionally added a fourth member, oftentimes a fifth, as the Court of Directors judge proper. At preſent the council conſiſts of four. Theſe are the immediate repreſentatives of the lords proprietors, and the ſuperintending agents of all their concerns at the iſland. They are alſo juſtices of the peace and commiſſioners of oyer and terminer and gaol delivery, and they exerciſe the juriſdiction of the eccleſiaſtical court, in granting letters of adminiſtration, proving of wills, &c. The governor is excluſively entruſted with the powers of the ſecret committee of the court of directors when the council is not aſſembled. The authority of the whole board concentrates in him; and, by charter from the crown, when there is occaſion, he may exerciſe the powers of captain-general. The civil eſtabliſhment conſiſts of an accountant, pay-maſter, ſtore-keeper, and the ſecretary to government, with their aſſiſtants, ſome of whom are the heads of inferior departments, and promotions take place by ſeniority. The military force of the iſland is compoſed of a corps of artillery, commanded by a lieutenant-colonel; a regiment of infantry, and five companies of white and black militia, who are at preſent upon the footing of volunteers. The governor is allowed a town and country reſidence, and a liberal table, at the expence of the company, with ſervants, horſes, &c. The lieutenant-governor has likewiſe the privilege of a town and country-houſe, ſome land, ſervants, and a few horſes. The other member or members of council are each allowed a town reſidence; and, by the orders of the court of directors, dated 1796, the remaining company's houſes were allotted to the two principal ſervants next to council, the engineer, chaplain, and head-ſurgeon.

As to the natural hiſtory of the iſland, it ſeems to have had a volcanic origin, as volcanic productions abound on its ſurface, emulating thoſe of Sicily and Italy. St. Helena is gifted with conſiderable attractions and advantages, both local and natural. The temperature and ſalubrity of the climate are not exceeded in any part of the world; the variations of heat and cold are moderate, and generally fluctuate near the point moſt congenial to animal exiſtence; it is fanned by a conſtant and agreeable wind, ſurrounded by plenty and variety of fiſh, and refreſhed by numerous ſprings of excellent water; the ſecluſion of its inhabitants is relieved by the frequent arrival of viſitants; and this intercourſe checks and corrects their uniformity of life, and tends to improve both the manners and the mind. The climate ſeems to be particularly adapted to the conſtitutions of Europeans, of whom many have reſided here for a long ſeries of years without ſuffering any malady. The only endemic diſorders to which the natives are ſubject are of the catarrhal kind; theſe, as they belong to the inflammatory kind, may in ſome meaſure account, notwithſtanding their general robuſt health, for the few inſtances among the iſlanders of longevity. The anchorage in the road is ſafe and ſheltered; the ſurf, indeed, is occaſionally high and dangerous; but the ocean beyond it is never ruffled by thoſe hurricanes which in other climates occaſion ſo much diſtreſs. The approach from the S.E. is ſmooth and commodious; and in departing for Europe, the ſhip glides away before a gentle and a ſteady breeze.

This iſland was diſcovered by John de Nova, a Portugueſe officer, on the 21ſt of May, 1501, (the anniverſary of Helena, mother to the emperor Conſtantine), three years and ſix months after De Gama had firſt doubled the ſouthern promontory of Africa. At that time the iſland was only

inhabited by ſea-fowl, and occaſionally by ſeals, ſea-lions, and turtles. The interior of the iſland was one entire foreſt, and even ſome of the precipices that over-hang the ſea were covered with gumwood-trees. The other indigenous productions beſides the trees and ſhrubs, together with plenty of fine water, a mild climate, productive ſoil, and commodious anchorage, ſituated in the immediate track of ſhips ſailing from India to Europe, rendered St. Helena of infinite importance in the eſtimation of its diſcoverers. The firſt human occupiers of the iſland were Fernandez Lopez, a Portugueſe nobleman, and his companions, found at Goa by Albuberque, and by him baniſhed, who, in the year 1513, landed on this iſland, with a few negro ſlaves. Lopez ſought comfort in this ſolitude. Hogs, goats, and poultry were landed for his ſuſtenance; partridges, pheaſants, guinea-fowls, peacocks, and other wild fowl, were let looſe; roots and vegetables of various ſorts were alſo introduced; and figs, oranges, lemons, and peach-trees were planted. Every thing proſpered under his attention and culture. The Portugueſe were anxious to keep ſecret their diſcovery of this iſland, and ſucceeded in their wiſhes and endeavours for this purpoſe until the 8th of June 1588, when it was deſcried by captain Cavendiſh in his return from a circumnavigating voyage. He diſcovered a convenient anchorage, oppoſite to Chapel Valley, in twelve fathom water; and afterwards he particularly deſcribed the ſtate of the iſland. The next perſon from England, who viſited this iſland, was captain Lancaſter, who after a diſaſtrous voyage to India, reached St. Helena on the 3d of April, 1593. After the incorporation of the India company in the year 1600, captain Lancaſter in a trading voyage, undertaken by order of this company, found the importance of this iſland, and after repairing his damages and refreſhing himſelf and his exhauſted men upon it, he arrived ſafe in England September 11, 1603. At this period St. Helena was likewiſe known to the Dutch and Spaniards, who made uſe of it as a convenient place of refreſhment. The Portugueſe, it is ſaid, were driven out of the iſland by the Dutch, who ſucceeded the former in the poſſeſſion of it, and retained it till the year 1651, when, eſtabliſhing a colony at the Cape of Good Hope, they abandoned St. Helena. On this event the Eaſt India company ſettled on it in the ſame year; and ten years after obtained the continued poſſeſſion of it by a charter from king Charles II. After this charter they took pains in ſtocking and improving it; and after the year 1666, the iſland received a conſiderable ſupply of inhabitants in conſequence of the dreadful fire in London. The Dutch, indeed, recovered it again in 1665, but in leſs than twelve months, the Engliſh regained their poſſeſſion. No fortifications ſeem to have been built upon it either by the Portugueſe or Dutch. The firſt fort appears to have been a triangular redoubt, erected in 1665, called Fort James, in compliment to the duke of York, afterwards king James II. The appellation of James's valley is derived from the old fort, and that of Chapel Valley from the Portugueſe chapel, the ruins of which were viſible when the iſland was firſt ſettled by the Engliſh. The Dutch recovered it again, but it was retaken by ſir Richard Munden, and upon his arrival in England, the poſſeſſion or government of it were again aſſigned by the king to the Eaſt India company, and a charter was granted December 16, 1673, conſtituting them lords proprietors of the iſland, with the rights and powers of ſovereignty. In their poſſeſſion it has ſince continued, and has been found of great importance and utility as a place of refreſhment or rendezvous in its connection with the India navigation and trade. Brooke's Hiſt. of the Iſland of St. Helena, 1808.

HELENA, *St.* an iſland of America, 30 miles in circumference, on the coaſt of South Carolina, which, with the main land on the N. forms St. Helena ſound, and gives name to a pariſh in Beaufort diſtrict, conſiſting of a cluſter of iſlands.—Alſo, a town on the coaſt of Florida, built by the Spaniards, and burnt by ſir Francis Drake in 1585.—Alſo, a town of the iſland of Scio.—Alſo, a town of South America, in the province of Quito; eight miles W. of Guayaquil.

HELENI, a town of Abyſſinia; 30 miles S.S.E. of Siré.

HELENIA, in *Botany*, Gærtn. t. 169. See HELENIUM.

HELENIUM, is an American genus, ſo named by Linnæus after he had referred the original *Helenium* to *Inula*. Ελενιον of Dioſcorides was thus called, as profeſſor Martyn informs us, in honour of Helen, the wife of Menelaus, who, as Heſychius ſays, cultivated a plant that deſtroyed ſerpents: according to others it ſprung from her tears. *Inula Helenium*, elecampane, is undoubtedly the ancient plant; and becauſe the genus we are about to deſcribe, in many reſpects cloſely reſembles the plant of Dioſcorides, Linnæus adopted this name for it. He firſt called it *Helenia* in the *Hortus Cliffortianus*, which termination Gærtner has retained. But in all the reſt of Linnæus's works the genus is found under the more claſſical title of *Helenium*.—Linn. Gen. 429. Schreb. 560. Willd. Sp. Pl. v. 3. 2120. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 227. Juſſ. 189. Lamarck. Dict. v. 3. 81. Illuſtr. t. 688. Gærtn. t. 169.—Claſs and order, *Syngeneſia Polygamia-Superflua*. Nat. Ord. *Compoſitæ Diſcoideæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common calyx* ſimple, of one leaf, ſpreading, divided into about 20 ſegments which are gradually attenuated. *Cor.* compound, radiated; *florets* of the diſk perfect, numerous, tubular, ſhorter than the calyx, four or five-toothed; thoſe of the radius female, equal in number to the ſegments of the calyx, ligulate, broader outwards, three-cleft at the top, longer than the calyx. *Stam.* (in the tubular florets) Filaments five, capillary, very ſhort; anthers cylindrical, tubular. *Piſt.* (in the tubular florets) Germen oblong; ſtyle thread-ſhaped, as long as the ſtamens; ſtigma cloven: the female or ligulate florets differ in having the ſtyle very ſhort. *Peric.* none, except the unchanged calyx. *Seeds* in the florets, both of the diſk and radius, ſolitary, obovate, angular, crowned with a ſmall, five-toothed, partial calyx. *Recept.* naked, convex; the ſcales of the calyx merely ſeparating the florets of the radius.

Eſſ. Ch. Receptacle naked; that of the radius chaffy. Down with five awns. Calyx of one leaf, in many deep ſegments. Florets of the radius three-cleft.

1. H. *autumnale*. Linn. Sp. Pl. 1248. Pluk. Phyt. t. 372. f. 4.—"Leaves ſerrated, very ſmooth."—Native of damp places in North America, flowering from Auguſt to October. The whole plant is extremely bitter. This hardy perennial riſes to the height of ſix or ſeven feet. Many branching *ſtems* ſpring from the *root*. *Leaves* elliptic-lanceolate, ſmooth, alternate, more or leſs deeply ſerrated. *Flowers* large, yellow, numerous, on terminal, finely downy ſtalks; the radius marked with ſtrong parallel ribs.

2. H *longifolium* (H. autumnale; Mill. Dict ed. 8.)—Leaves linear-lanceolate, entire, very ſmooth. Flower-ſtalks elongated, naked.—Native of North America. A more ſlender plant than the laſt, with *leaves* twice or thrice as long, much narrower, and entire, or ſlightly waved. The *flower-ſtalks* are greatly elongated, and naked. Cornuti's *Aſter luteus alatus*, Canad. 62. t. 63, rather reſembles this than the former, but we dare not poſitively quote it.

3. H. *pubescens*. Ait. Hort. Kew. v. 3. 227.—"Leaves serrated, downy."—Native also of North America.—This is all the account we have of it.

4. H. *quadridentatum*. Billardiere Act. Soc. Hist. Nat. de Paris, v. 1. 22. t. 4. Michaux Boreal-Amer. v. 2. 133. (Rudbeckia alata; Jacq. Ic. Rar. t. 593.)—Upper leaves entire, smooth, broad at the base. Florets of the disk four-cleft.—Native of Carolina and Louisiana. We received it from Kew Garden in 1797. The *root* is annual. *Stem* two feet high, much branched, strongly winged from the decurrent *leaves*, which are lanceolate, broad at the base, smooth, or very nearly so; the upper ones quite entire, the lower somewhat serrated, or even pinnatifid. *Flowers* much smaller than the other species, being scarcely an inch broad, orange-coloured, with broad-wedge-shaped three-lobed florets in the radius, and those of the disk four-cleft only; not five-cleft, as is almost universally the case in this natural order. The *flower-stalks* are long, slender, simple, naked, terminal, and solitary.

HELENS, St. in *Geography*, is a small town and parish in East Medina Liberty, Isle of Wight, England. It has a bay of considerable note as a rendezvous for the royal navy; and in time of war is a place of great maritime traffic, the East India fleet generally stopping here for water and provisions. At the mouth of the bay is a cluster of rocks called the Mixen. The houses in St. Helens are neatly built with stone, and thatched: their number, at the time of the late return to parliament, was 100, the inhabitants 550. The ancient church was partly taken down about the beginning of the last century, the church-yard having been encroached on by the sea: the tower was suffered to remain as a mark for seamen. The new church is a small edifice, standing in a more elevated situation to the north-west of the town.

In this parish, opposite St. Helens' road, was a priory for Cluniac monks, founded about the middle of the twelfth century, and made subordinate to an abbey in Normandy. The scite of the ancient building is now occupied by the seat of sir Nash Grose, one of the judges of the Court of King's Bench, whose mansion, denominated Priory, commands extensive views of the Hampshire and Sussex coasts. This edifice, which has been much enlarged by the present possessor, stands at the head of a spacious lawn, that declines from the house to the brink of a high ridge, the steep bank of which is covered with wood down to the water's edge. In the southern part of the wood are the remains of an ancient watch-tower, supposed to have belonged to the priory. The whole of this demesne is formed of a narrow slip of ground, extending about a mile along the shore.

At a small distance north-west from Priory is Fairy-Hill, the seat of the Rev. Henry Oglander; the house is a neat structure, and the grounds are pleasantly disposed. On the sea-shore, near Old Fort, is a saltern. Beauties of England and Wales. Worsley's History, &c. of the Isle of Wight, 4to.—Also, a bay on the coast of Africa; 30 miles N. of Saldenha bay. S. lat. 32° 40'.

HELENUS, in *Fabulous History*, a celebrated soothsayer, the son of Priam and Hecuba. He married Andromache, the wife of Hector and slave of Pyrrhus, who gave her to him in marriage, because his predictions had been favourable to him. He was the only one of Priam's children who survived the ruin of his country. After the death of Pyrrhus he reigned over part of Epirus, called Chaonia. His son, Cestrinus, succeeded to a part of his father's dominions, called Cestrina. Helenus is said to have learned the art of divination from Cassandra his sister, the priestess of Apollo. Possessed of this art, he was much respected by the Trojans; and being taken prisoner, in his retirement to mount Ida, by Ulysses, he was much urged by the Greeks to reveal the secrets of the Trojans, and was at length prevailed upon to inform the enemies of his country that Troy could not be taken whilst it was in possession of the Palladium, nor before Polydectes, leaving his retreat at Lemnos, joined in supporting the siege. When his country was ruined he became the property of Pyrrhus, whose life he saved by warning him to avoid a dangerous tempest, which proved fatal to all those who set sail. Thus, as we have already said, he gained the favour of Pyrrhus, and his favour was introductory to the other events that occurred. It is said that Helenus received Æneas when on his voyage towards Italy, and predicted to him some of the calamities that befel his fleet.

HELEPOLIS, in *Antiquity*, a military machine for battering down the walls of a place besieged.

The word is Greek ἑλεπολις; compounded of the words ἑλειν, *to take*, and πολις, *a city*.

The helepolis, as described by Diodorus Siculus, &c. appears to have been no more than the aries or battering-ram, with a roof or covering over it, to prevent its being set on fire, as also to screen the men who worked it. Some will have it a combination of two or three battering-rams, moving on large strong wheels, roofed over, and covered with raw or wet skins. It had several iron points or heads, wherewith the execution was done, formed much like the thunderbolts which painters represent. Within was a great number of soldiers, who drove it with force of arm, and by means of ropes, violently against the wall where the breach was intended.

Others will have helepolis a generical name, comprehending all the machines used by the ancients in besieging towns; as, among us, the name artillery includes all the sorts of large fire-arms. But this opinion is chiefly founded on the origin of the name, and does by no means suit with those minute descriptions given of the helepolis in the ancient writers.

The invention of the helepolis, and divers other military machines, is ascribed to Demetrius; which, with the great number of cities he took thereby, gave him the denomination of *Poliorcetes*, or city-taker.

HELESAY, in *Geography*, one of the smaller Scots Hebrides. N. lat. 57°. W. long. 7° 20'.

HELFING, in our *Old Writers*, a brass coin among the Saxons, equivalent to our halfpenny.

HELGA, in *Geography*, a lake of Sweden, in the province of Smaland; five miles S. of Wetter lake.

HELGOM, a town of Sweden, in Angermannland; 46 miles N.W. of Hernosand.

HELIACA, formed from ἡλιος, *sun* in *Antiquity*, sacrifices and other solemnities performed in honour of the sun.

HELIACAL, of ἡλιος, *sun*, in *Astronomy*, applied to the *rising of a star, planet*, &c. denotes its issuing or emerging out of the rays and lustre of the sun, wherein it was before hid; whether this be owing to the recess of the sun from the star; or that of the star from the sun. When applied to the setting of a star, it denotes entering or immerging into the sun's rays and so becoming inconspicuous by the superior light of that luminary.

A star rises heliacally, when after it has been in conjunction with the sun, and on that account invisible, it gets at such a distance from him, as to be seen in the morning before the sun's rising.

The same is said to set heliacally, when it approaches so near the sun as to be hid therein. So that, in strictness, the heliacal rising and setting are only an apparition and occultation.

The heliacal rising of the moon happens when she arrives at

at the diſtance of 17 degrees from the ſun; for the other planets, 20 degrees diſtance is required: and for the ſtars more or leſs, as they are greater or ſmaller. See ARCH *of Viſion*.

The ancients computed that a ſtar, between the tropics, would be forty days before it got clear of the ſun's rays, and became conſpicuous again. Heſiod firſt made this computation, and the reſt followed him. The period comes very near to the computation of the moderns; for the ſun advancing nearly a degree every day, it will be twenty days approaching to it, from the heliacal ſetting of the ſtar, and thirty days more withdrawing, till the heliacal riſing.

Some nations of America, and particularly the inhabitants of Cayenne, regulate their civil year by the courſe of Sirius, beginning it with the heliacal riſing of that ſtar.

To find the HELIACAL *riſing and ſetting by the globe*, ſee GLOBE.

HELIACAL *Year*. See CANICULAR and *Egyptian* YEAR.

HELIADES, in *Mythology*, the daughters of the Sun and Clymenes, according to the poets: they were ſo afflicted, as they ſay, with the death of their brother Phaeton, that the gods, moved with the paſſion, transformed them into poplars on the banks of the river Eridanus.

HELIANTHEMUM, in *Botany*, from ἥλιος, *the ſun*, and ἄνθεμον, *a flower*, becauſe the bright yellow flowers expand only in the ſunſhine. Tourn. t. 128. Juſſ. 294. Gærtn. t. 76.—This genus, ſeparated from *Ciſtus* by the above authors, who are followed, as we underſtand, by ſome more recent ones, conſiſts of thoſe dwarf ſpecies, generally with yellow flowers, found on expoſed ſunny hills in various parts of Europe, many if not all of which are remarkable for the irritability of their ſtamens. They certainly differ from the true genus of *Ciſtus* in having only three valves to their fruit, which is reported to be of but one cell. We find it however of three cells in *Helianthemum thymifolium*. Another character, remarked by Gærtner, is, that the ſeeds are inſerted into the valves, whereas in *Ciſtus* they grow on the axis, or central column, of the capſule. The calyx-leaves are rather more unequal in *Helianthemum* than in *Ciſtus*, and the habit of the plants is unqueſtionably different. See CISTUS, ſection 2d.

HELIANTHUS, derived from ἥλιος, *the ſun*, and ἄνθος, *a flower*, is a genus univerſally known under the title of Sun-flower. This name originated from the reſemblance which its broad golden diſk and ray bear to the ſun, and is rendered further appropriate by its having the power (which indeed other ſyngeneſious plants poſſeſs) of conſtantly preſenting its flowers to that luminary. This order of plants is only endued, in a very high degree, with the ſame quality that is common to the whole vegetable world, of preſenting themſelves to the light; though this property, where it is eminently conſpicuous, has been poetically conſtrued into a ſort of ſympathy or perception in the plant, like the ancient Heliotrope.—Linn. Gen. 439. Schreb. 573. Willd. Sp. Pl. v. 3. 2237. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 248. Juſſ. 189. Lamarck. Dict. v. 3. 82. Illuſtr. t. 706. Gærtn. t. 172; (Corona Solis; Tournef. t. 279.)—Claſs and order, *Syngeneſia Polygamia Fruſtranea*. Nat. Ord. *Compoſitæ oppoſitifoliæ*, Linn. *Corymbiferæ*, Juſſ.
